Oswego, N. Y., Aug. 23—A group of financiers in this and neighboring cities has about completed plans for the formation of an automobile manufacturing corporation. It is expected that papers will be requested within a few days, and work upon the new plant being built for the Ontario Industrial Company, at the foot of West Albany street, is being rushed. One car has already been finished for experimental purposes, with a four-cylinder motor, an extra long wheelbase, and other modern features, and others are to be manufactured for 1910 delivery. The following appear as backers of the concern: Col. John T. Mott, C. C. Place, H. A. Wilcox, John P. Miller, D. W. Pell, T. P. Kingsford, A. N. Radcliffe, George E. Farrell, A. H. Mowry, James Dowdle, L. W. Mott, B. S. Adler, H. J. Wilhelm, T. A. Clarke and E. B. Powell.

WILLYS PREDICTS GREAT YEAR FOR EUROPEAN INDUSTRY

NEW YORK, Aug. 21—Contrary to the prevalent opinion in this country, that the European automobile industry has perhaps reached the zenith of its progress, are the ideas expressed by John N. Willys, on his return this week from a round of foreign factories. Although traveling ostensibly on a vacation trip, his connection with the automobile industry in this nation, as president of the Overland Automobile Company and the Marion Motor Car Company, of Indianapolis, led him to give the situation across the Atlantic a serious study. For two months he watched the wholesale and retail business, the work of the various factories, and the trend of the general activity in England, France, Italy, Belgium and Switzerland. His impression is that 1910 will unquestionably be the greatest year in the history of the European automobile industry, based not only upon the work in connection with pleasure vehicles, but even more so with the commercial and taxicab departments.

"The automobile industry in Europe held many surprises for me," says Mr. Willys, "for I had the opinion that it was declining, but I believe that the opposite is the real situation. The entire effort of the factories, however, is being directed only along the lines of taxicabs, commercial vehicles, and high-priced pleasure machines. The development of the low or medium-priced automobiles has been almost neglected. Paris, London, and other large centers are fairly alive with taxicabs. In New York, Boston, Chicago, and other American cities we think that a great quantity of these machines are in use, but the numbers being employed cannot compare with those in the English capital and on the Continent. Roughly counting, I do not believe it exaggeration to state that there are at least 5,000 automobile cabs in Paris and 2,000 in London.

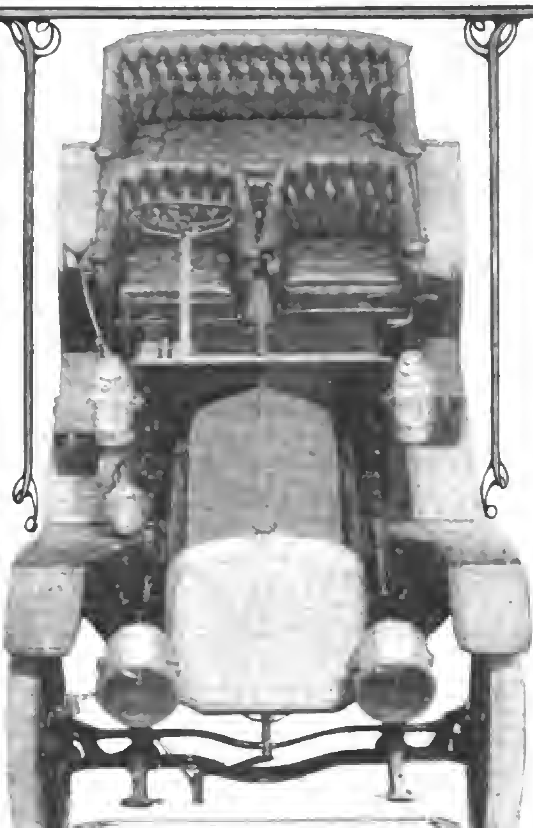
"The same applies to the business in commercial vehicles, in which there has been great progress. The last five years have made wonderful changes in traffic conditions abroad, and it is hardly conceivable that in such a short time so much of the horse-drawn movement could have been supplanted by the motor-driven machines. There are hundreds of auto-buses in London and Paris, and scores in all large cities, some double-decked, but usually with a single deck, to facilitate handling. I was greatly impressed by the prevalence of limousines, landaulets, and other types of high-priced European cars, as compared to the general use of these machines in this country, including those of domestic make, of course. The surprise was induced, probably, by the absence of the low-priced or medium-priced class, for but few of this kind are made, due principally to the fact that the manufacturers have confined themselves to the powerful and expensive output.

"In my opinion there is an excellent field abroad for medium-priced American machines of good quality, and it is the intention of our concerns to enter that business as soon as we are able to care for the American demand for Overlands and Marions. Just when this will be is indefinite. The European automobile public is gradually coming to believe in the American production, and is about ready to purchase imported goods, providing that the models are successful, and not the over-production. The business should be started conservatively, however, so as not to antagonize the foreigners with reports of a so-called 'invasion.' The success of the moderate size cars in this country has influenced the designers on the other side to give attention to this type; but, as yet, their small cars cannot compare with ours. They concede the American superiority, and I believe that it will take them some time to be able to construct machines that will equal our own. They do not have the up-to-date machinery to give large output, unless they have gotten it from America. It was noticeable to me that the manufacturers with whom I spoke do not consider the American small cars sneeringly, as they once did. Rather they gaze upon our industry with respect, and perhaps with fear.

CORBIN APPEARS IN 1910 FORM

SLIGHT modifications in the motor, a lengthened wheelbase, a heavier frame and additional equipment are the principal changes in the "Full Jeweled" Corbin for 1910. The model which was so successful during the passing season has been retained nearly in its entirety, the only details altered being characterized as distinct refinements. Produced by the Corbin Motor Vehicle Corporation at New Britain, Conn., associated with other large manufacturing establishments, the cars have been the results of splendid engineering skill and knowledge, and it is the announced intention of the factory that the same standards shall be maintained throughout the immediate as well as future seasons.

As in the past the efforts of the entire force will be concentrated upon a single model, giving the experiences gained in five years of making Corbins, and some of the constructive details proven in the models in which they were pioneers are important still. With one type of chassis will come two motors, either water or air-cooled, though the latter will be made only on special order, and the two engines are interchangeable, of course, with their individual fittings. The success of the 1909 season was so marked that the prospects become bright for an even more flourishing one ahead and orders for material sufficient for 600 automobiles have either been let or are pending. It is planned by the officials to turn out that number of cars during the 1910 period and already deliveries have been going on for a month.



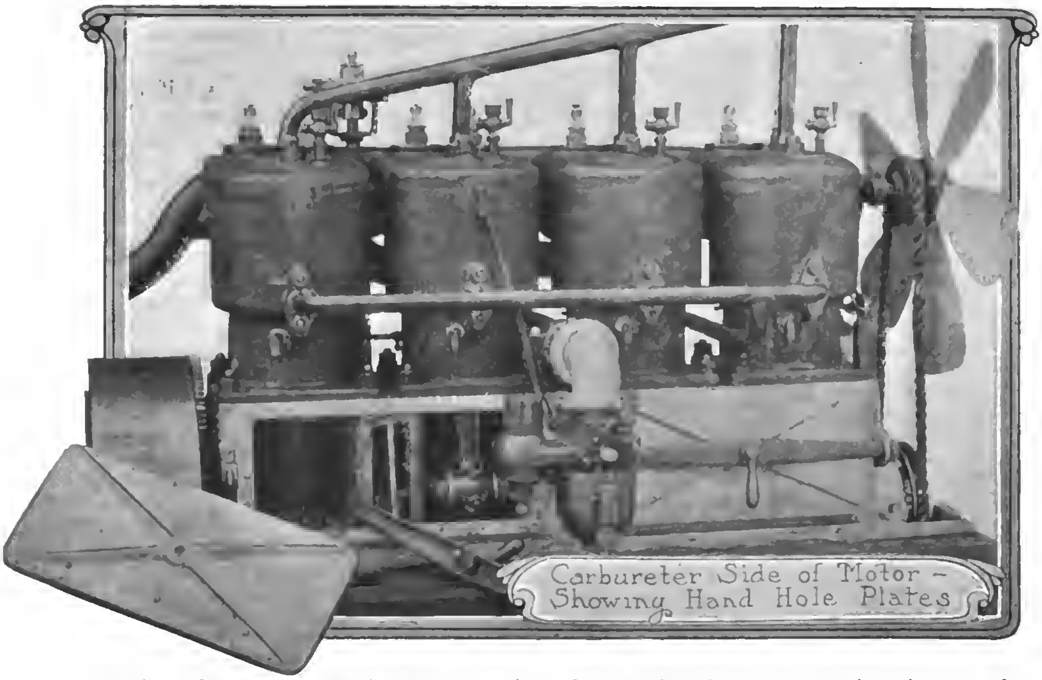
Baby Tonneau Body

Details of the Changes in New Models—As has become somewhat general among the stable members of the industry, standardization has been attained to such a degree that few deviations are necessary. In the new Corbins this will be well illustrated, for the variations from previous practice may be counted upon the fingers of one hand. In the motor itself the principal ones include enclosed timing gears, a new type of oil pump and a changed location, and the moving of the magneto from the front inlet side to the rear exhaust side. The oil pump was formerly mounted midway on the exhaust side and driven directly from the camshaft, but now it is further back on the same side and is driven by the same helical gear which operates the distributor. The pump is now a centrifugal one instead of plain-gear and forces oil from the reservoir, under the foot-boards, through dash sight feeds to the four cylinders and thence to the crankcase for splash. The two-to-one or timing gears remain at the forward end of the case and are enclosed in an aluminum oil-tight case. A Bosch magneto is now regular equipment and this is placed at the rear of the exhaust side and driven by aluminum to fiber gears from the camshaft. In previous models this has been extra equipment and provision was made to drive it from the timing gears at the front next to the carbureter. The change keeps all moving parts on one side.

In the chassis the frame has been lengthened 2 1-2 inches and this put into the wheelbase to insure greater comfort in riding. To make this possible the frame members have been made 1 inch deeper in section. Looking toward the same end, that of ease, the tires are now 4 inches in diameter all around instead of 3 1-2 front and 4 in the rear. Hartford universal joints are used in the driving mechanism and the driving shafts in the rear axle are made of vanadium, instead of nickel, steel. A slight change has been made in the engine support whereby a lighter steel beam is introduced to transmit the torque reaction from the engine to the side frame members. The engine is supported as previously, but the steel beam takes the place of a deeper and heavier one of aluminum.

Arrangement of the Corbin Motor—No departure has been made in the type of water-cooled motor used in 1909, it having four cylinders cast separately with the valves all on one side—the left looking forward. The bore is 4 1-2 inches and stroke 4 1-4 inches. The exhaust and inlet manifolds are held in place by a series of four yokes, the exhaust pipe going directly to the rear, while the inlet takes a turn between the second and third cylinders to the carbureter on the other side. The single camshaft is driven from the enclosed gears at the front, operating not only the cams, but also the water and oil pumps, the distributor, and the magneto. The fan is mounted upon the front cylinder and driven by a rope belt which is held under tension by a spring and lever arm. The water enters the pump at the bottom, is forced to the jackets from the opposite side, the piping passing between the first and second cylinders, and is returned to the honeycomb radiator through a copper tapered manifold on the top. By the use of single cylinder castings a five-bearing crankshaft is permitted with plain bearings of Parsons white brass between the cylinders and the two end supports are of the annular ball type.

The aluminum crankcase is divided, the lower half being held by through bolts which at the upper end hold the cylinders down on the upper half. This is a construction which secures great simplicity. To inspect the interior of the case there are two very large hand holes on the carbureter side of the upper crankcase half and the connecting rod bearings may be taken up through these. Their size makes the operation very easy and an entire piston and connecting rod may be removed without disturbing the rest of the motor. Another point of accessibility is secured in the manner of holding the cam rollers. These are pinned in such a way that with the withdrawal of a cotter pin and by sliding the bolt to one side the roller may be removed through the crankcase hand holes from the opposite side. The hand hole covers are retained by a yoke and single turn screw, so that they can be removed in a twinkling. A relief cock is placed in the head of each cylinder. Inspection of the timing gears is facilitated through the use of a separate casting cover held in place by three cap screws. The entire water system is so designed that it can be taken off or put on with no difficulty, the former operation being confined to the un-



clutch with three springs is used to transmit the power from the flywheel through a keyed shaft, with a sliding joint to allow vertical freedom. The clutch is held in the flywheel by three powerful seating springs and the thrust taken up in a ball bearing. A long lever arm on the foot clutch-pedal makes the operation of the clutch easy and the disengaging mechanism is as simple as possible, ball bearings being employed on the end of the fork.

Three forward and one reverse speeds are secured in the compact selective sliding gear transmission. This is placed immediately at the rear of the clutch-engaging assembly with the shifting rod entering it at the top just under a removable cover plate. The case itself is of aluminum in halves so arranged that the gears, slide bars and operating levers all act in oil. The gears are made of high-grade steel, case-hardened and

coupling of two unions and the unloosening of a castellated nut to remove the pump and then the regular process of taking off two manifolds. These arrangements aid in caring for the car.

The addition of the magneto to the list of regular equipment now gives the Corbin a double set, the one with the Bosch magneto and a one-point Connecticut coil and the other with a Connecticut coil and distributor, using a storage battery or six dry cells as source of current. The magneto, as has been explained, is driven directly through gears and is readily accessible. The wires are led between the second and third cylinders, a guide being arranged on the top of the inlet manifold, to the fiber cable-lead and thence to the spark plugs. The magneto plugs are placed over the inlet valves, inasmuch as most of the running will be done with this system, while the batteries have a set over the exhaust valves, but in the same pockets. The distributor is controlled from the lever on the steering wheel through bevel gears at the base of the column and a rod passing between the third and fourth cylinders.

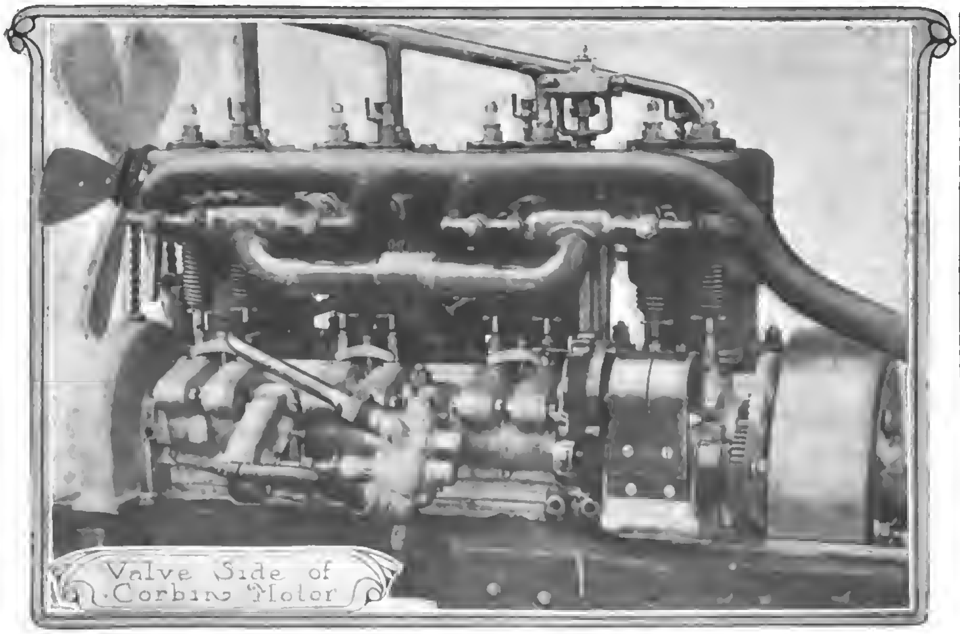
A water-jacketed Schebler carbureter is used, controlled also from the top of the steering column and a single rod. A foot throttle is also connected, operated by a piano-type push pedal.

Clutch and Transmission Assembly—A leather-faced cone

ground, and the shafts are supported on F & S imported annual ball bearings. The final drive is by shaft through two Hartford universal joints to a semi-floating rear axle. The shafts are of nickel steel, heat-treated and mounted upon annual ball bearings with a special bearing to take care of the thrust. There are seven annular and two thrust bearings in the rear construction, making this expensive, but being conducive to longer life and less wear. The driving pinion itself has three of the annular and one of the thrust bearings. The torsion strain is taken from the rear axle by a long tubular rod extending to the cross-frame member just at the rear of the transmission and its end is there held between spring bumpers. The spring seats are oscillating to give an easier motion to the body of the car and to place less strain upon the rear construction. The gears and differential can be removed without removing the axle from the car, by taking off the upper half of the housing.

Two complete sets of double-acting brakes are placed upon the rear wheels, one set—the external—is operated by the foot pedal, and the other by a hand lever at the side, as is general practice. The former brakes are floating bands lined with camel's hair, and a flat spring on the outside keeps them from dragging upon the drum when not engaged. Bronze shoes acting upon the steel drum constitute the internal system and both are so arranged that the pressure upon them from either the foot or the lever is very great. The springs are all long, of the semi-elliptic type, and the rear ones have a scroll turn at the rear with a spiral spring tending to give easy-riding properties.

Steering Gear—A worm and sector irreversible steering gear is used in the new models as in those in the past in which it gave great satisfaction. The teeth are cut by the Hindley process which gives long bearing surfaces thereby preventing quick wear, and the sector and sectorshaft are made in one drop forging, mounted on bearings of bronze. The wheel itself is made of wood with a finish which protects it from water and keeps the color constant. The spark and throttle operating levers are placed upon a stationary quad-



rant in the center of the steering wheel. Ball thrust bearings above and below the steering worm tend to reduce to a minimum all wear, and together with the ball bearings in the pivot heads, make the steering remarkably easy.

The I-beam front axle is a one-piece drop forging of alloy steel properly tempered, with large jaws at each end to receive the pivots and with the spring seats integral. The pivots have large ball bearings at the top to take both the load and the steering strain. A distinctive feature of the Corbin front axle construction is seen in the fact that no through bolts are used to hold the pivots in place, but the forging is so made that the pivots cannot be forced out except by removing a bushing in the lower jaw of the axle. The bushing is held in place by two cotter pins. The steering cross rod is placed at the rear of the axle, thus being protected from any possible damage from road obstructions. All nuts in the system are castellated, and due provision is made for adjustments to take up the ordinary wear in the joints. The cross rod is dropped in the center, conforming to the shape of the axle, and to obviate any chance of its hitting the dust pan under the engine.

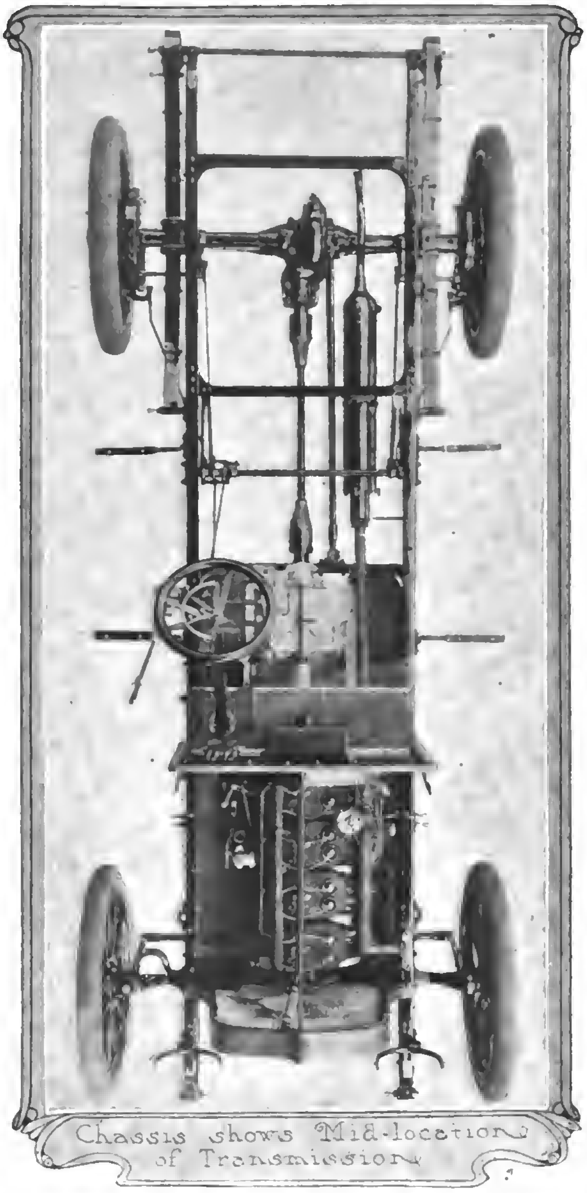
The air-cooled motor will this season be installed in cars only on order, but the construction is such that there is no difficulty in making the change when the car is purchased or built. The method of attaching the engine to the frame is the same in both cases, as is the ignition, oiling and transmission connections. The cylinders are of the same size as the water-

Dash Board and Control Mechanism

cooled ones, but are different in the essential construction aside from the difference in cooling. Their bore is 4 1-2 inches and the stroke 4 1-4 inches, but the valves are in the head, operated by push rods and rocker arms. There is but one camshaft and this works both valve tappet rod sets, the exhaust directly above it and the inlet through a set of rocker arms in the crankcase. The valves are located in cages in the head of the cylinders. Cooling is effected through a series of sheet metal flanges set spirally in the cylinder walls and the wavelike shape gives the air a better chance to touch the entire surface. The coming season will be the third for this type of air-cooled motor.

Four Body Models—The Corbin Company, while concentrating its attention upon one chassis, will give an option of four different styles of bodies—the five-passenger touring car, the four-passenger roadster, the four-passenger baby tonneau and the limousine. The only appreciable difference necessitated in the chassis by any of these is that the wheelbase for the limousine is 6 inches longer than for the others. The standard length is now 110 inches and the enclosed model will be 116. For the roadster and baby tonneau cars the steering column is given a slightly increased rake and the gear ratio may be altered if desired. Inasmuch as the equipment now includes the magneto, the Prest-O-Lite tank and the cape top, the price has been raised from $2,500 to $2,750, with the enclosed cars, of course, proportionately more, but the increase is less than that to which the purchaser was put in equipping his car heretofore. The color finish of the cars will be to some extent optional, for a number of choices are offered in the new catalogues. Another wide range of choice is seen in the fact that any make of American tires will be placed upon the car, according to specifications. Body lines on the 1909 cars were so well liked that the alterations are minor ones, the fenders, general appearance, and finish being of the same character, with just sufficient variations to distinguish them as new models.

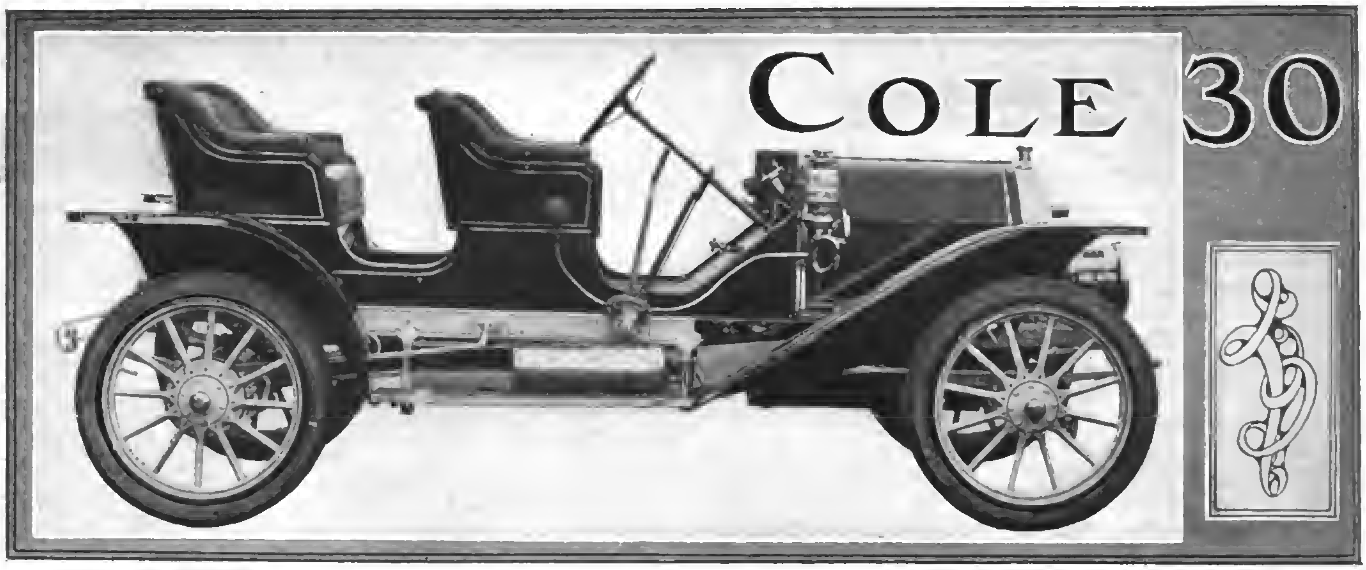
The familiar trademark, "Full Jeweled," will also be among the features retained, for the cause of its first application is still found in the large number of annular bearings used. There are 20 of these, distributed as follows: four in the front



Chassis shows Mid-location of Transmission

wheels, two on the crankshaft, five in the transmission, seven in the rear axle, and two in the clutch. These enable the car to be moved with the minimum of frictional resistance, consequently reducing the loss between the motor and the road wheels, and at the same time increasing the efficiency of the entire machine.

Throughout the spring the extensive factory of the Corbin Company has been working steadily upon the output, so that with the completion of the season it was well prepared to enter upon the new orders. Material has been going through for some weeks, and machine work is being done in advance to be ready for the urgent demands. Night work has not been found necessary with the existing facilities, but from present indications it may become imperative very shortly.

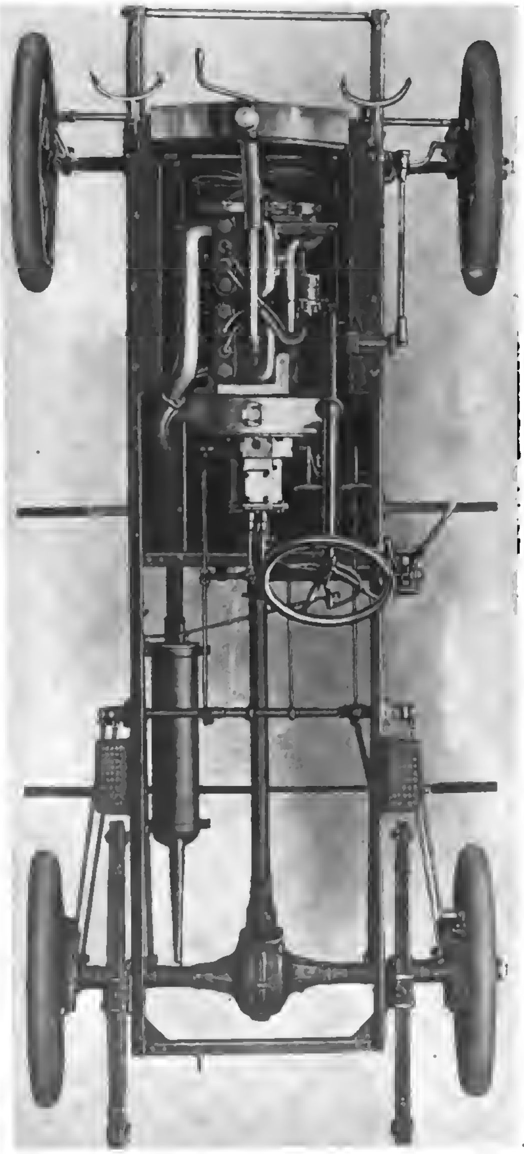


NEW among the cars for 1910 is the Cole "30," which, however, shows no new and untried features but is constructed upon correct and accepted lines, which have shown merit in the past. It is an Indianapolis production, being built by the Cole Motor Car Company of that city, and sold by the Henderson Motor Sales Company. Wisdom is shown in the election to build but a single model, upon which factory and sales effort will be concentrated, this being named the Cole "30."

In this, the source of power is a four-cylinder motor, comprising part of a unit power plant located at the front end of the chassis, driving back through a slightly inclined shaft to the live rear axle. The engine has the 4 by 4 cylinders cast in pairs, with the valves all placed on the left side. This form of construction makes the engine very simple, for there is but one camshaft, one set of cams, and all valves being located close together, repairs or adjustments are more easily made. To avoid complicating the motor, the magneto, a regular part of the equipment, is placed on the right side, as is also the water pump.

Connected to the motor as an integral part, is the clutch, which is of the cone type. This is of the direct cone variety, the removable clutch leather surfaces working directly on the flywheel proper. In it, as in the whole power plant, and in fact, throughout the car, simplicity has been sought and attained. As few parts are used as will actually do the work, which means a great deal to the prospective owner, since fewer parts means fewer sources of wear, lesser number of joints to wear loose and a smaller number of parts to be repaired, in case of accident.

Not only is the clutch made one with the engine, the cases of the two being rigidly fastened together, but the transmission case, also, is joined to the other two. This form of construction, combined with the suspension which it allows, keeps the bearings, the vital parts of any piece of mechanism, in constant and perfect alignment. Not only does this make for easy assembling at the factory, but in the hands of the user, in daily service, the same alignment may be confidently counted upon. The whole thing spells ease of operation and increase in the power delivered to the rear wheels, which after all, is the desideratum. The transmission affords three speeds and reverse, operating on the selective plan, with a positive locking device which prevents two gears being used at once.



Chassis of Cole "30" Viewed from Above

A self-contained oiling system of this motor makes all other oilers unnecessary. The oil is filled in through the breather by removing the cap of same, the oil gauge just to the left of the carbureter clearly indicates by the rise and fall of the aluminum ball the amount of oil in the reservoir, a full supply of oil is indicated when the ball is near the top of the open slot, and time to put oil into the motor is indicated when the ball is at the bottom of the open slot. A plunger pump connects the oil reservoir with the crank case proper and circulates the oil continually, depending upon the speed of the motor, and maintaining at all times proper level. All excess of oil overflows to the reservoir. A pet cock on the outside, near the top of the pump, when opened will indicate whether or not the pump is operating.

Full floating describes the rear axle, which is mounted upon Hyatt flexible roller bearings, while the I-section front axle has ball bearings to carry the load. Two sets of brakes are fitted, one internal expanding, the other, band brakes on the outside of the brake drum. The wheelbase is 108 inches and the wheels, 32 inch, equipped with 3½-inch tires all around.

FRENCH SPEEDOMETER SHOWS SPEED, TIME AND DISTANCES

By W. F. BRADLEY

PARIS, Aug. 19—Perhaps the only objection that can be brought against an accurate modern speedometer is that it is ephemeral. It gives the speed at which the car is traveling while the car is in motion. When the car stops the pointer drops back to zero, and nothing more is to be learned from the clock-like dial. On certain instruments the maximum speed remains permanently recorded, but even this is a meager record compared with the one supplied by a new European instrument.

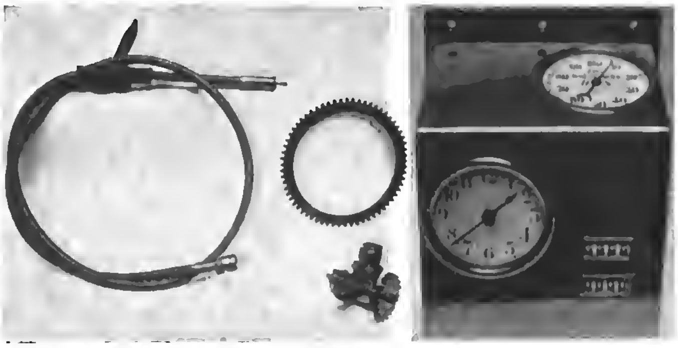
The O.S. register shows the speed at which the car is traveling, in the same way as the usual type of speed indicator, and at the same time prints, on a narrow strip of paper, an account of all that has been done by the automobile from the moment it is taken out of the garage to the instant it is brought back again. If it is desired to know, for instance, what the car was doing between 3 and 4 in the afternoon, it is only necessary to look up the band and everything will be found in black and white: the speed minute by minute; the exact minute when each stop was made, how long the stop lasted, at what time the car started, etc.

The matter is really simple, although it may at first sight appear to be too complicated an operation to be connected with simplicity. Within the brass box containing the speedometer is a roll of paper about one inch in width, which is unrolled from one spindle to another at a determined rate. The paper bears horizontal and vertical lines, these latter representing minutes, fifteen minutes and hours. The band is driven by clockwork mechanism, the passage of each one of the vertical bars representing one minute. The horizontal bars represent each ten kilometers, and run up from ten to 100 kilometers.

As soon as the car is put into motion and the speedometer, operated in the usual way by flexible cable from a front wheel, starts to act, a stencil begins to trace a line on the moving band of paper, passing under it at the rate of one vertical space a minute. Where the diagram crosses the horizontal lines it shows the speed, and at the vertical lines, the hour that speed took place.

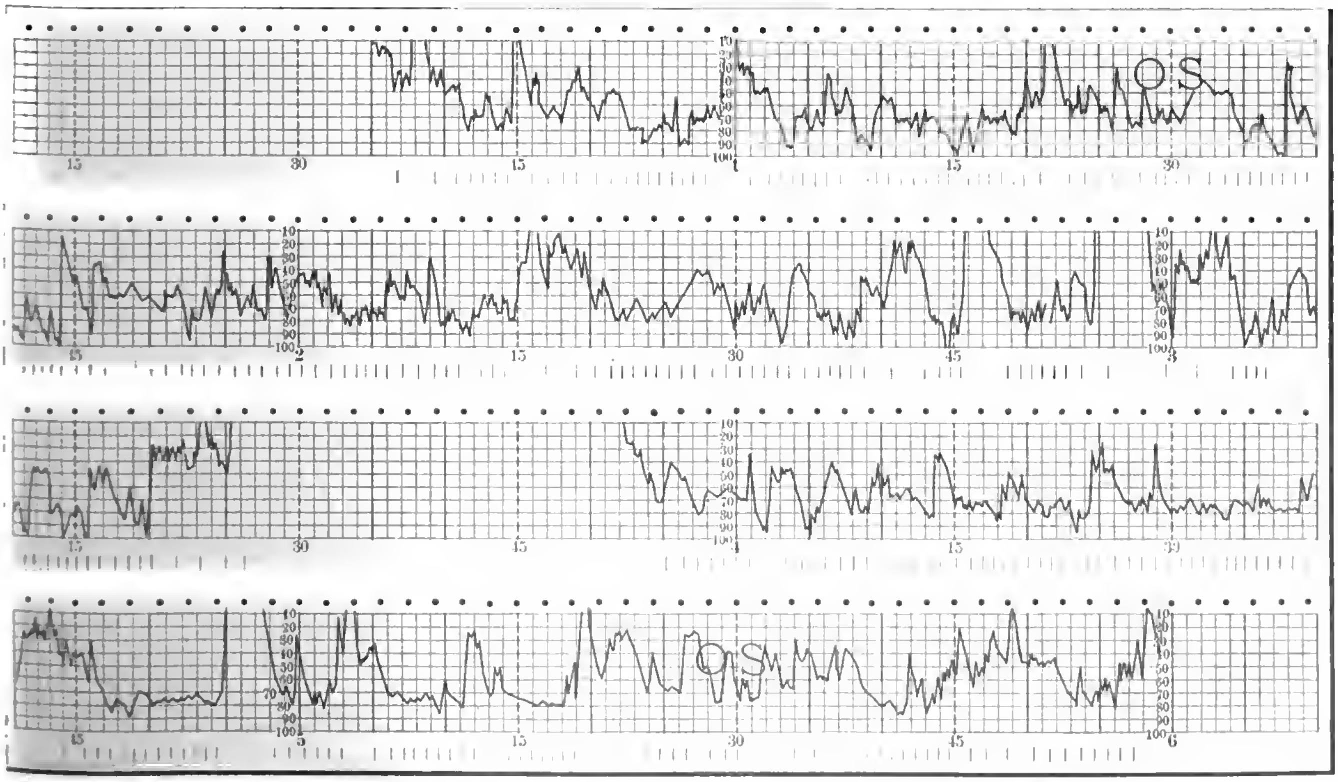
The following is an example of the reading taken on a trial run with a fast touring car fitted with this apparatus. Car started at 12.35. After two minutes the speed rises to 50 kilometers an hour. After three minutes grade crossing and stoppage of one minute. The speed gradually increases to 80 kilometers an hour, with one or two periods where it drops back to 60 kilometers. At 12.45 stop of half a minute, and at 12.59 stop of 45 seconds. At 1.04 the speed is 93 kilometers; at 1.09 it is 95 kilometers; at 1.15 it is 100 kilometers.

The recording bands are supplied in lengths for 12, 18 and 24 hours' duration. They are very easily put into position, and once placed the door of the instrument can be locked, making it impossible for the driver to tamper with the record. So long as



Driving Shaft, Gears and Enclosed Box of O.S. Speed Register

the speedometer is doing its duty the permanent record will be made. From a sporting standpoint it is interesting to be able to keep a permanent record of what has been done by the car each day, and for the private owner it is valuable to have some check on his driver when the car is out of his sight. If the instrument can be produced at a sufficiently low price to make it accessible, it should have a great future on commercial vehicles, where a moderate speed and the reasonable use of the brakes are both absolutely necessary for the long life of the car. At present, the cost is rather above the means of the average owner.



Sample Chart as Spoken of in Text, Showing How the Recorder Indicates Time, Speed and Distance

BOURDREAUX-VERDET BALL-BEARING MOTOR

INGENUITY is rarely so well displayed as it is in connection with the application of ball bearings to motors, and that the automobile industry has heard the last word is scarcely to be taken for granted. Some motors lend ease to the application of ball bearings, and the one as here illustrated is in this class. This application, as presented by Henry Hess—Hess-Bright Manufacturing Co.—shows how nicely the Hess-Bright (D.W.F.) type of bearings work in, and it happens to be the case that the motor, aside from the question of ball bearings, is of more than passing interest as a type.

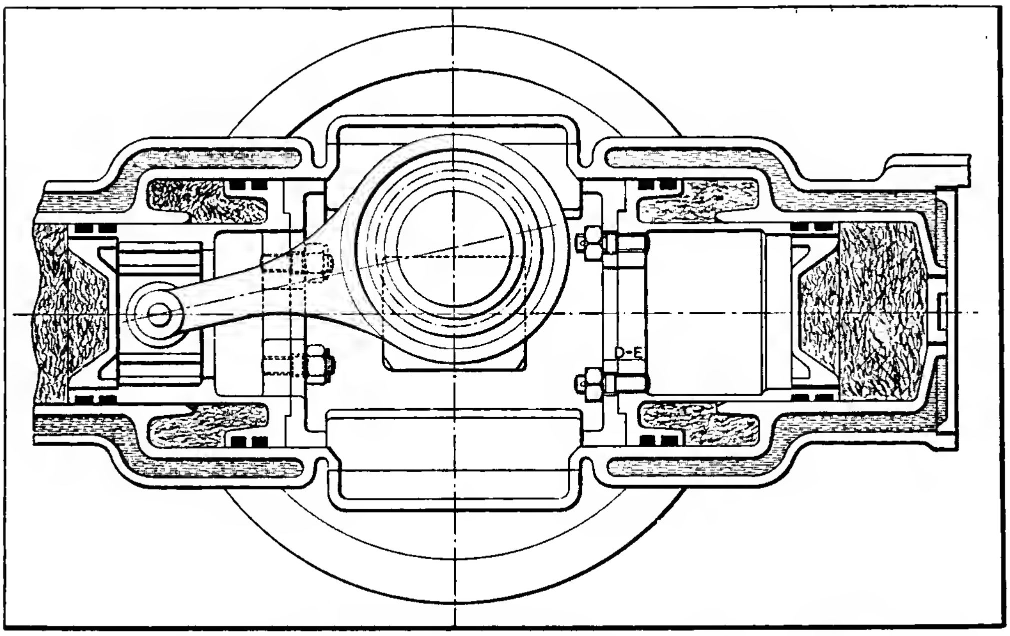


Fig. 1—Cross-section through cylinders, showing concentric piston and thicknesses of walls

As will be observed, the motor is of the concentric-piston type, designed to operate four-cycle, giving results such as the two-cycle motor is supposed to afford, in that there is one explosion for each revolution. With the small piston having 10.2 square inches area (the concentric piston having the same area) and a stroke of four inches, the compression is 80 pounds per square inch, giving seven horsepower, at 1,100 revolutions per minute, for a single cylinder.

But this, in the abstract, is not so much to be wondered at; what is more to the point is the constant torque reported for this motor and the fact that the power increased with speed as follows:

INCREASE OF POWER WITH INCREASING SPEED

Speed in Revolutions per Minute	H.P.	Torque in Foot-pounds
1,100	7	32
1,250	8.5	..
1,425	9.75	..
1,560	10.6	36

The above is for one cylinder, and, as will be observed, the torque was very nearly constant throughout the range of speed, which is a rather unusual performance, especially at the rather high speeds named. The power, in view of the nearly constant torque, increased with the speed almost in proportion, and the weight efficiency of the motor, in view of its lightness, is very good indeed.

Among the mechanical features, as clearly depicted in Fig. 1, and further indicated in Fig. 2, is the connection between the two systems of pistons, and the use of a common connecting-rod. Then, as the same figures show, the crankshaft is short, strong and well balanced, considering the type of motor. The piston construction is a little heavy, which is a matter of moment in motors in general; but in this case, owing to the rigidity of the parts and the great ability of the ball bearings selected, the results are not marred by the weight of the reciprocating parts, and the test, as reported, shows adequately the ability of the bearings, crankshaft and connecting parts.

The cylinders are properly water-jacketed, and the ports, which do not show in the section are sufficiently large to adequately serve the purpose. The construction in general is on a rather high plane, and, on the whole, this is a good illustration of what can be done outside of the conventional; and in view of the present uneasiness among designers, as evidenced by the many new examples which are constantly being presented, it may prove of more than a little interest at this time not only to show the trend from the point of view of ball bearings, but in the direction of the increase in weight efficiency of motors, which is a matter of increasing the number of power strokes, in a given time, without increasing the number of cylinders or the total weight of the power plant.

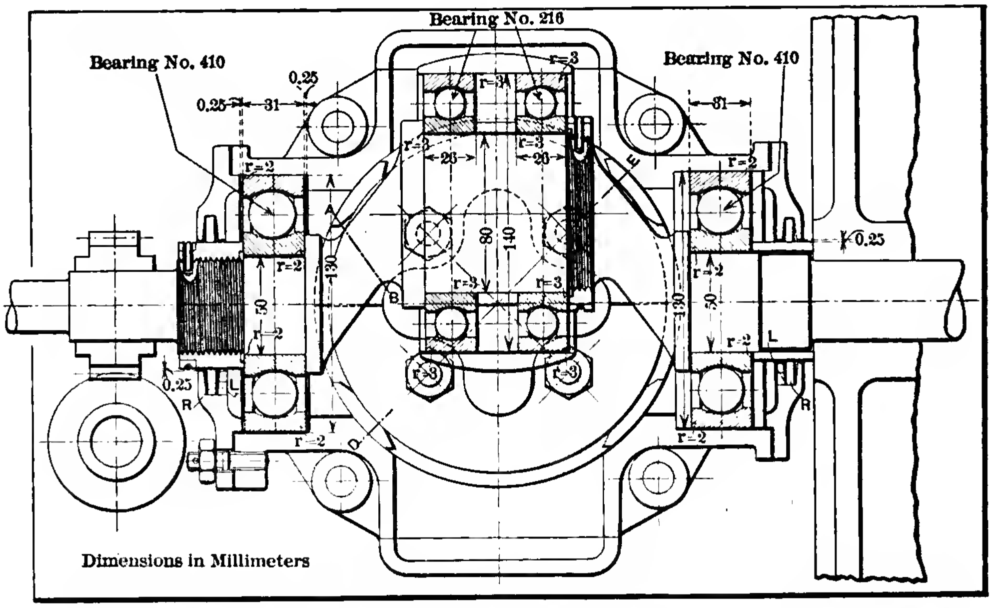

Fig. 2—Cross-section through crankshaft, depicting the manner of applying ball bearings

Regal Completes Its Transcontinental

Ames Monument over 8,000 feet above Sea Level

Along the Cliffs, Weber Canyon Utah

Crossing Desert Sands Western Utah.

Fording a Wyoming Stream

SAN FRANCISCO, Aug. 22—Thirty days out from New York, running time, and with the odometer reading 4031.5 miles, the Regal transcontinentalist ended its strenuous journey at the Regal agency on Golden Gate avenue, in the best of condition and ready to duplicate the trip. The experiences of the party as far as Rawlins, Wyo., have already been described. The final stretch may best be left to the fervid and flowery rhetoric of George D. Wilcox.

"It is a wise provision of Nature," begins the tale of the Regal Xenophon, "that we poor mortals may not know what the future holds in store for us, else our gay start from Rawlins on that bright Sunday morning would have immediately changed into a feeling as of one going forth to slaughter. Heading westward along the tracks of the Union Pacific road we found ourselves in a rough, rolling country of steep ascents, but fairly good road surface." Here he pauses to relate a coyote story in the Seton-Thompson style. Continuing: "Wamsutter, on the eastern edge of the Red Desert, was the noon stop, and after filling the water bags we tackled the road across this barren waste. How we ever got the car through this hundred miles of country we hardly know.

"Bitter Creek, a sluggish alkali stream, rose to a raging flood and tore into the soggy banks like a steam shovel. For forty-eight hours we waited in the old stone stage house, a relic of the Indian days. Tuesday afternoon we ventured forth, and five miles out came to the first washout. We plunged in; the water rose into the body and over the motor, and we stopped in midstream all awash. We held a council of war and devised methods of extraction, which finally were rewarded with success. Across the Green River and southwest into a mighty canyon we plunged, determined to make Granger, 45 miles away, for the night stop. The road improved somewhat, but with Granger only five miles distant, our searchlight disclosed the walls of another washout directly across our path. Its walls were precipices, its bottom fathomless mud. Scouting parties discovered an opening. The Regal was brought up, rushed the ford and sank in a sickening manner in quicksand just at the moment when a safe passage seemed sure. One look was enough; we decided to camp by the car till daylight.

"In that high altitude the nights were bitter cold, and a sage-brush fire, unless constantly fed, is a failure; so all night long we alternately froze and roasted. Daylight and the sun warmed our blood enough to begin the work of rescue, which we accomplished in due time. At Granger we found that we must run north to Oakley, thence south to Evanston, a detour of 75 miles, to avoid more washouts. Night found us at Opal, and in the morning we were off early for Evanston. However, we took a wrong turn, and after 32 miles of "Seeing Wyoming" we were back again whence we started. Again we were instructed, and hitting the right road south, made a fast run into Evanston, arriving at 6 p. m.

"Who can describe the grandeur of this ride through the great natural gateway that opens before us permitting our escape to the beautiful valley in which Ogden is nested?" Mr. Wilcox gallantly attempts the description: "Range on range of magnificent snow-clad mountains pile themselves to the north and south. The Weber River roaring through the narrow gorge gives scant foothold for the wagon road, which, perched now upon one shoulder, again on the opposite of the cliff, winds under the shadow of the great overhanging rocks. The road is superb. At last, filled with the grandeur and majesty of this wonderful pass, we break through the Devil's Gate and come abruptly into the level and beautiful valley. We were received in Ogden with open arms.

"Ogden is the gateway to the great desert; six hundred miles to the west lies Reno. Saturday afternoon found us again under way after adding to our already overloaded car a supply of provisions, extra water bags and tires. The road led into rough, broken country, and we bumped up and down long hills, thrashing through sagebrush and greasewood wheel high. We crossed the marsh at the head of Salt Lake instead of climbing on the abandoned railroad right of way. Ten miles wide and as white as snow it lies, seemingly as smooth and safe as a cement walk; but the fragile white crust conceals a swamp of pasty, black mud. We hasten on, and finally reach the hills and safety, arriving in Lucin at 9 p. m. Sunday.

Struggles with Sand and Sage-Brush

"We celebrated our entrance into Nevada the next morning with a struggle with fifteen miles of sand. The only possible way that a car could progress was by means of canvas strips on which it must run. We had provided ourselves with several of these, each 100 feet long and two feet wide, and we spent the entire day getting into Montello, 20 miles, in this manner. We left for Wells the following day and again tackled the desert. Don't imagine the Nevada desert a smooth, sandy plain—far from it. It's climb up and down all day long, and the grades are wonders for steepness and roughness.

"On Friday we reached Lovelock at 3 p. m., and thence bowled along for 20 miles, skirting the northern edge of the alkali desert, into which the Humbolt River so mysteriously sinks. Westward, as far as we could see, the white, salt-incrusted plain stretched to the setting sun. Southward the mountains, and the railway at their base, receded into the dim, hazy distance, and to the north the broken foothills lay barren and desolate. We spun along, but how seemingly slow the progress; it is as though we remained in the very center of this deserted land and the wheels revolved under us idly." Here the faithful reader encounters a marvelous tale of a band of wild horses, led by a "magnificent white animal." Hardly had these disappeared, when as darkness dropped down, we realized that without water and food we were lost in the dreaded sink. The car was traveling on a thin crust of sun-baked mud, under which the treacherous black ooze threatened to mire us. At last we reached the foothills and encountered a well-defined trail. We drove into Leet's Station in time for the savory ham and eggs of the Sunday morning breakfast.

"From here we followed the Southern Pacific into Wadsworth, 20 miles, and arrived in Reno, 35 miles from Wadsworth, at 2 p. m., where we enjoyed the luxury of a bath in a real tub and sleep in a real bed. Reno, with its electric cars, paved streets and modern hotels, looked bigger than New York to us. On the morrow, rested and refreshed, we started southward on the last lap of the 'long trail' to the Golden Gate.

Crossing the Sierras into California

"The road wound through a narrow canyon along the eastern slope of the mountains, skirted the shore of beautiful Washoe Lake, and then, ascending a high divide, dropped us down suddenly into Carson City. We rushed through the broad main street and after a run across country over a superb road we reached Wally's Hot Springs. Six o'clock in the morning found us away, and turning directly into an enormous canyon, we confronted the 'Grade.' The road was ankle deep in equal parts of fine sand and disintegrated granite in which the wheels sink to the rims, and it ascends the mountain in a series of great sweeping switchbacks winding, snakelike, back and forth up a mighty spud, so deep that in a quarter of a mile's travel you look down 200 feet on the road directly below you over which you have just come.

"We start abruptly down the Pacific Slope among giant fir trees and come out on the shores of beautiful Lake Tahoe at lunch time. The lake, blue as the sky above, with its setting of snow-clad mountains, glimmers like an immense topaz 7000 feet above the sea. The road, built and maintained by the State, is a credit to the commonwealth. Its cost must have been immense, hewn out of the cliff side as it is. We go down, down, down, in a seemingly unending succession of curves, now under overhanging cliffs, now buried in the semi-darkness of a pine forest. After a hurried meal at Placerville, we headed northwest and reached Sacramento at 1 a. m., having covered 164 miles.

"We get away on the last lap in great style next morning. Down through Stockton and Livermore we fly to Oakland. We finish the great run with a final rush up Market street, in our hearts and minds nothing but gratitude and pleasant recollections to those and of those who so kindly contributed to our success and pleasures en route."

Wearied by the strait confines of prose, Mr. Wilcox concludes his recital with a burst of verse in the true epic mood:

"We have lived an age in a half-moon wane;
We have seen a world; we have chased the sun
From sea to sea—but the task is done.
We here descend to the Great White Main,
To the King of Seas with its temples bare,
And a tropic's breath on brow and hair."

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

- Sept. 21-23.......Cleveland, Good Roads Convention, American Automobile Association.
- Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers. Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.
- Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
- Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
- Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.
- Feb. 22-26 ....Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

Races, Hill Climbs, Etc.

- Aug. 27-28.......New York City, Brighton Beach, 24-Hour Race, Motor Racing Association.
- Sept. 6-11.......Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
- Sept. 10-11.......Baltimore, 24-Hour Race, Motor Car Racing Association of Maryland.
- Sept. 15..........Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
- Sept. 20-22.......New York, Second Annual Run Around Long Island, New York Automobile Trade Association.
- Sept. 21..........Riverhead, L. I., Long Island Derby, Motor Contest Association.
- Sept. 21-29.......Washington-Boston and Return, Munsey Reliability Run.
- Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City M. C.
- Oct. 16...........Denver, Col., Start of "Flag to Flag" Reliability Run, G. A. Wahlgreen, Manager.
- Nov. 9............Atlanta, Ga., Track Races, Atlanta Automobile Association.
- Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

What the Clubs Are Doing These Days

ROCHESTER CLUB HAS LARGE MEMBERSHIP

ROCHESTER, N. Y., Aug. 23—The Automobile Club of Rochester is fast becoming one of the largest automobile organizations in this country. With the additions at its last election the roll now includes over 700 names and there are more applications on hand at present. It is the hope of the members of the body that this club may be soon counted upon the very largest in this respect. Considerable activity along lines of good roads, legislative and touring work has been outlined for fall campaigns.

The recent fifth annual orphans' day was the most successful ever held by the club. There were 585 children and 50 attendants as guests for the day and 172 automobiles in which to entertain them. The passengers were secured at 1 o'clock in the afternoon from the various asylums, the parade formed and ride around the city taken as a preliminary to the rest of the day's fun. The line of cars was preceded by a motor-cycle police squad and a large truck carrying a band. At Ontario Beach Park every concession was thrown open and refreshments distributed freely. The children from each home were assigned certain colors and their cars decorated accordingly, so that loading and unloading was greatly facilitated. This was an arrangement made by Secretary Bert Van Tuyle.

NEW AUTO CLUBHOUSE AT WILDWOOD, N. J.

WILDWOOD-BY-THE-SEA, N. J., Aug. 21—Although but six weeks old, the North Wildwood Motor Club is a healthy infant, as was evidenced by the fact that to-night it had a "house-warming" in its new quarters, at the junction of Central boulevard and Seventeenth street. The clubhouse is a cosy and comfortable structure, having two-story porches and a roof-garden, besides accommodations for such of its members as may desire to use the clubhouse as headquarters during their stay in the resort. The membership list contains the names of many prominent in automobile and newspaper circles in the Quaker City. W. Wayne Davis, manager of the Matheson branch in Philadelphia, is president; the Mayor of North Wildwood, Harry C. Wheaton, is vice-president; William C. Richardson, treasurer; William E. Young and E. M. Omensetter, secretaries, and Charles Winters, counsel. Plans are in progress to hold a meet on the Central Avenue speedway before the close of the present season.

EAST ST. LOUIS NOW HAS A CLUB

EAST ST. LOUIS, ILL., Aug. 23—With a charter membership of 22, the Automobile Club of East St. Louis has been formed in this place, as a direct result of an accident to a boy a few days previous. The traffic rules have been so lax and children so foolhardy on the street that these autoists banded together to secure some action from the local council. It will seek to have the children prevented from running at large on the business streets, and to make it a misdemeanor to throw bottles, glass, tacks and similar articles out where auto tires may be affected. The following officers were elected: President A. B. Sager; secretary and treasurer, James E. Combs.

QUAKERS PLAN RECEPTION FOR MUNSEY TOUR

PHILADELPHIA, Aug. 23—When the Munseyites arrive here on September 21, en route from Washington to Boston, they will be taken in tow by the Quaker City Motor Club, whose house committee, under the leadership of Frank Hardart, Sr., and A. T. James, will entertain the visitors with a smoker and concert in the huge banquet hall of the Hotel Walton. "Doc" Overbeck, the Quaker's scout, has been named as one of the committee of technical sharps to look over the cars after the run.

WASHINGTONIANS PREPARING FLORAL PARADE

WASHINGTON, D. C., Aug. 21—The automobile floral parade of the Chamber of Commerce, assisted by the Automobile Club of Washington, scheduled for September 30, and the Munsey tour to Boston and return, September 21-29, are two projects that are attracting a great deal of interest among local automobilists. The floral parade is expected to be one of the greatest events of the kind ever held in this section. The announcement that President Taft's big White steamer would probably head the parade has caused it to assume national importance. It is also expected that the several members of the Taft cabinet will enter their cars, each of which will fly the departmental flag of its chief. Various other cars owned by the Federal Government will make up the balance of the Government section, and then will come the Munsey tourists. The flag-decorated cars will compose the next section, followed by the floral decorated cars. The last section will be devoted to commercial vehicles. Handsome prizes have been offered, including a sweepstakes cup valued at $600.

NEW ROCHELLE AUTOISTS FORM CLUB

NEW ROCHELLE, N. Y., Aug. 23—Marked enthusiasm for the new organization accompanied the formation of the Automobile Club of New Rochelle on Thursday evening. With about 250 automobile owners in this city, the charter membership of the club is nearly 50, and it is expected that this will increase by leaps and bounds in the near future. The poor condition of some of the streets, and certain conditions which have arisen to bother autoists, led to the call for the local body. It is planned to begin at once upon plans for a clubhouse and garage, and the constitution permits the club to take active part in aeronautics, a subject in which many of the members are particularly interested. The officers elected are: President, E. T. Birdsall; first vice-president, W. B. Ogden, Jr.; second vice-president, J. A. Schofield; secretary, F. M. Carpenter; treasurer, F. D. LeCount; governors, A. F. Bradley, T. N. Benedict, G. W. Sutton, E. Eckart, Robert Fox and G. A. Peck.

SUCCESSFUL ANNUAL TOUR OF WINNIPEGGERS

MINNEAPOLIS, MINN., Aug. 21—Ten cars made the run here via Grand Forks and Fargo, in the annual tour of the Winnipeg Automobile Club last week. Pathfinder McLeod utilized a unique method of marking the course, by placing a funnel through the footboard of the car and using ordinary white beans instead of confetti.

The tourists were entertained by friends in St. Paul and Minneapolis for two days, and returned via the same route.

NORFOLK ORPHANS GIVEN AN OUTING

NORFOLK, VA., Aug. 14—Under the auspices of the Tidewater Automobile Association, 115 little orphan children were given an outing on Wednesday. Twenty cars were donated for the occasion and the three institutions in the city furnished the occupants. They were taken to Ocean View, where the amusements were thrown open to them, and later a lunch provided.

NEW CLUB FORMED IN ABILENE, KAN.

ABILENE, KAN., Aug. 21—The Abilene Automobile Club was organized in this city this week with the following officers: President, C. M. Harger; vice-president, F. H. Forney; secretary and treasurer, J. T. Nicolay. All the towns of the county will be canvassed for members, and inasmuch as good roads will be the object of the body, farmers will be asked to join.

RACING A PROBLEMATICAL SPORT

Disastrous and disheartening was the initiation of the Indianapolis motor speedway, the fatalities supplying ammunition to those who believe that high speed in automobile competition has nearly reached its conclusion. But, apparently, the end is not yet for contests of this character in America, and, while the element of danger is ever involved, a lesson can be learned from the Indiana race-course which should prevent a recurrence of such an unfortunate innings of sport. This lesson has been taken to heart by the builders themselves, who keenly feel the regrettable opening.

In order to keep faith with the public, as well as with the contestants themselves, the promoters of the stupendous undertaking at Indianapolis rushed their construction to a completion which left much undone when the workmen were driven from the course to make way for the impatient participants in the racing. The track, in its hastily prepared condition, could not withstand the horde of high-powered speed craft, and soon the surface had disintegrated in such manner as to make it positively dangerous. Furthermore, the distances in the feature events were too great for track contests wherein only one driver to a car is employed.

Human endurance has its limits, and men should not be encouraged to exert themselves beyond their capabilities, either in the pursuit of glory or gold, or both. These defects can be avoided on another occasion, though it must always be borne in mind that high-speed automobile racing is not a lawn tennis match or a genteel kind of game, which means that there will be occasional sacrifices to this fierce god of sport, the supporting of which rests entirely with the manufacturers, not a few of whom are now asking themselves whether it pays.

The promoters of the great undertaking at Indianapolis were actuated by a desire to excel anything of the kind ever before attempted in this country, and the seeking of profits unquestionably was secondary, for none believed that such a hazardous venture would be successful financially in a city of moderate size. The wish was to supply a course as safe as can be obtained for mile-a-minute and faster racing. The first inclination, after the frightful introductory, was an abandonment of the entire project, but a revised judgment has brought forth the announcement that $100,000 additional, if necessary, will be utilized in providing all safeguards possible to drivers and spectators.

Here is expressed the sincere hope that no more lives will be cut short in the racing at Indianapolis; but one can never lose sight of the fact that high-speed racing in its sanest aspect involves a risk perhaps only exceeded by the spectacular aeroplane in its abrupt entrance upon the scene; and the man of the air may assert that his sport is even less perilous than that of the fellow who hurtles himself around a track or over winding roads in a machine tested to its utmost endurance, remembering that a thing is only as strong as its weakest part.

DEVELOPMENT IN BODY DESIGN

Improvement in automobile body design has fully kept pace with improvement in the motive power and running gear. We can all remember the bulges and scrolls of the "Roi des Belges" so popular five years ago, which enjoyed the triple distinction of being offensive to the eye, painful to the spinal column, and back-breaking for the unfortunate chassis. Our newer body work is simple in outline and decoration; it relies for effect on proportion and the arrangement of masses. Its simple lines permit a lighter and more mechanical construction, and the graceful reverse curve beloved of the artist no longer catches the unhappy passenger in the small of the back. The depth of the seats and the foot-room have been worked out with some regard for human anatomy; this done, the body builders have made that world-old discovery that utility is the larger half of art.

The most significant development has been that in "baby" and close-coupled tonneaus. The remarkable popularity of these designs indicates that the desire for excessive seating capacity is no longer dominant. A most sensible and logical body, at least in respect to size, was shown on a foreign car in one of the New York shows, but failed to receive the attention that it deserved. It was of the close-coupled type, but the rear seat was divided so as to provide comfortable accommodation for two persons. In addition, there was a single folding seat in the middle, instead of the customary pair. This arrangement seems ideal. Four makes a good party; and, if there should be a fifth, he would be at least as comfortable on the auxiliary seat as in the middle of the usual tonneau seat. Everyone forced to occupy that seat will join in a prayer for its early abolition.

ATLANTA'S NATIONAL SHOW PLANS ANNOUNCED

NEW YORK, Aug. 23—First of the forthcoming national automobile shows is that at Atlanta, and the entire South is interested in it. The exhibition is welcomed there by tradesmen and owners alike as a means of stirring additional enthusiasm for this method of locomotion, and of further awakening that section of the country. The automobile is already working wonders toward opening up the States which have lain idle for years, and with the coming of this event of such wide importance a strong economic result is expected. It was really this event which suggested to the promoters of the New York to Atlanta endurance contest the idea of running down to the exhibition, and thus arouse enthusiasm for good roads.

The Southern show will be held in the Auditorium-Armory, and by the removal of various partitions there will be 65,000 square feet of floor space available. The structure is one of the largest buildings for exhibition purposes in that section of the country, and, under the ownership of the city of Atlanta, has been used for some of the largest of conventions. The show will be held from November 6 to 13, under the management of Samuel A. Miles, general manager of the National Association of Automobile Manufacturers, and of Alfred Reeves, general manager of the American Motor Car Manufacturers' Association.

The applications for space and diagrams of the floor arrangement have been mailed to the makers of automobiles and accessories, and to be considered in the first allotment, these must be returned to the headquarters of the N. A. A. M., No. 7 East Forty-second street, New York, by September 4. No application received after that date will be taken up until the others have been cared for. The first allotment will take place September 8.

Those working in conjunction with Messrs. Miles and Reeves are Asa G. Chandler, president of the Atlanta Chamber of Commerce; John S. Cohen, Clark Howell, E. W. Gans, S. C. Dobbs, C. R. Ryan, E. M. Hanson, J. T. Fitten, and others, all of Atlanta.

VANDERVOORT EXPLAINS HIS PROTEST OF HOWER AWARD

NEW YORK, Aug. 24—After refraining from discussion of the subject the past few weeks, W. H. VanDerVoort, president of the Moline Automobile Company, has consented to tell the facts regarding his protest against awarding the Hower trophy in the recent Glidden tour. Mr. VanDerVoort does not wish it to be thought that his protest was merely on the matter of carrying a tail-light, and in his statement he explains where, in his judgement, a proper enforcement of the rules would have given the Hower trophy to the Moline. Mr. VanDerVoort says:

"I dislike very much to be involved in a protest of any sort, but many of the contestants in the tour almost demanded it, and I think my interest in the Moline and in fair play warrants it.

"Feeling that the text of my protest against the finding of the technical committee in the final inspection of the Glidden Tour cars at Kansas City should emanate from the office of the chairman, Mr. Hower, I have until this time refrained from giving out same.

"Noting, however, that an erroneous report has gone out to the effect that Moline car 101 was protesting the decision on the grounds of Pierce car 108 not carrying a tail-light, we feel that this impression should be corrected. Pierce car 108 did carry its tail-light, and my protest is based upon the fact that this tail-lamp was demolished and the bracket considerably bent.

"Penalties were provided for deterioration, and, according to the rules, car 108 should have been penalized to the extent of the price of a new lamp and the labor required to straighten the tail-lamp bracket. Moline car 101 was required to light its oil lamps in proving condition. This would have been impossible with car 108, as the tail-lamp was entirely inoperative.

"On the basis of material and labor in repairing bracket, and replacing lamp, it would alter the final score in my favor.

"I have no criticism whatever as to the findings of the committee upon penalties which were imposed upon Moline entry 101, and while the crushing of the tail-lamp and the bending of its bracket may appear trifling, I feel that the tightening of the three spring clip nuts and the furnishing of one 1/4x1-inch cap screw, and one 3/8x1-inch step bolt, upon which our penalties were levied, are, from the operative standpoint, of less importance.

"In the case of the protest against the perfect score Glidden car, the public has been led to believe that this was based upon the technical fact that the car did not carry its tail-lamp over a portion of the tour. While this is true, and under the rules should have been penalized, back of it all lies the fact that these lamps were purposely removed in order to prevent the breaking off of the bracket and the tool box, as happened to Pierce car 109 during the tour. As it is only fair to assume that had the tail-lamp been left on the two touring cars, they would both have suffered the same fate as befell the two roadsters."

NEW CONNECTICUT LAW IS AMENDED

HARTFORD, CONN., Aug. 21—When Governor Weeks signed the new automobile law, as stated last week, he did so with the provision that certain changes be made in it by amendments. These have been passed this week by both houses of the legislature and make some important alterations in the statute. The principal change is that in regard to the license fees, which have been changed from certain amounts upon different classes of power to a flat rate per power. Cars of less than 25 horsepower will be taxed at 50 cents for each horsepower, while those about the 25 figure will be rated at 60 cents each. The factories will have to pay only one dollar for each machine tested upon the roads, instead of double that amount. The proposed amendment that automobilists be required to stop when approaching street cars loading or unloading passengers was not included in the bill, thus allowing the three-miles-an-hour clause to remain.

COLUMBUS, O., DESIRES ROAD CONVENTION

COLUMBUS, O., Aug. 23—The Columbus chamber of commerce is making every effort to secure the next convention of the American Roadmakers' Association, which will be held in October. This body of highway builders is composed of some of the most prominent men in the country interested in good roads, representing every State. If the meeting is brought to this city it is likely that it will be held in connection with the annual gathering of the Ohio Good Roads Federation, October 27 to 29.

JONES SECURES INJUNCTION AGAINST I. A. L.

NEW YORK, Aug. 23—The Jones Speedometer Company announces that it has secured a restraining injunction in the U. S. Circuit Court of the Western District of New York, against the International Automobile League of Buffalo. This forbids the sale of Jones speedometers or parts at less than factory list prices.

AUTOISTS NOW LOOK TO LOWELL'S CARNIVAL OF SPEED

LOWELL, MASS., Aug. 23—With the termination of the races on the Indianapolis speedway, the attention of the automobile world is focussed on Lowell and the Merrimac Valley course as the next scene of competition in speed. Stock cars will have complete sway in the national events which will feature the carnival, starting on Labor Day and lasting throughout the week, and as the dates approach little else is thought of in this section. For many weeks the preparations have been going on, the course being treated, railroad facilities improved, and now, chief of all, the racing men are on their way with their swift machines. The committee in charge of the multifarious plans is about ready to state that the entire arrangements have been completed.

Work on the 10.6 mile circuit is nearly at an end, and only enough will be required to keep it in excellent condition for the events. The grand stand is receiving its finishing touches, as is also the pontoon bridge across the river, and the parking spaces have been staked off opposite the big stand and on the boulevard. It has been the aim of those in charge to have all the preliminary work done before the great majority of the ante-race crowd arrives. Many of the racing teams have secured their quarters, and it is advisable for everyone who intends to visit the city to reserve rooms well in advance. Those in charge of the matter have the location of 500 rooms for visitors on their lists, and will gives the names of the places upon application. Additional space is being secured daily, for it is felt that all will be needed. Preparations are made to include a crowd of from 125,000 to 150,000, and an endeavor will be made to keep down any tendency toward exorbitant charges on the part of the local dealers.

Last year, with 80,000 spectators along the course, 300 patrol guards succeeded in preventing accidents and in keeping the course well policed. During the big events next month the number will be increased to 500, of whom 400 will be local militiamen, and the others will be from the local police force. The men will be scattered around the route as last year, with the greatest number where the crowd is likely to congregate, and will be given instructions to keep people off the road at all cost. Wire fence has been used in some places to assist the police, and rope will be ready to stretch in case of any unusual gathering at some now unsuspected vantage point.

The latest entry is a new 50-horsepower Simplex car, a duplicate of the one with which George Robertson won the recent 24-hour track race. Its owner and entrant is Daniel Shea, and he is desirous of securing Robert Hilliard to handle it in the big race here. Hilliard won the light car race at Savannah last fall, and has been prominent in many contests of speed and endurance. The list of entries now includes the following: Three Maxwells, a Moon, an Allen-Kingston, a Columbia, an Isotta, a Mercedes, a Bergdoll, two Appersons, an Alco, two Renaults, Knoxes, Stoddard-Daytons, Benz and Rainiers. Walter Christie is expected to have his new 100-horsepower front wheel drive here for the straightaway speed trials on the day between the small chassis event and the big one for the Lowell trophy. The entries are still being received, so that a wonderful field of starters is expected.

SPECIALIZED CONDITIONS FOR FLAG TO FLAG CONTEST

DENVER, COL., Aug. 21—From Denver to Mexico City is the route over which the tourists in the Flag to Flag contest will be required to travel during the last week of October and the first half of the month of November. The date of the start has been announced as October 25, and that of the finish sometime in the week of November 15. Road conditions are such that the exact time can be figured but approximately, although the rules as announced give the schedule for the competition while under the Mexican banner. The contest is for the George A. Wahlgreen trophy, conducted under the sanction of the A. A. A., and with rules which are much similar to those of the 1909 Glidden tour. Necessary alterations have been made to conform with circumstances that will probably arise across the border. In addition to the prize offered by Mr. Wahlgreen for touring cars will be another for runabouts.

The rules have recently been issued, and chief interest in them is taken in that section which governs the contestants from Eagle Pass, the last city in this country, to the capital of the Aztecs. The regulations previous to the former point are well understood, including penalties for lateness at night controls, the use of observers throughout the daily trips, penalizations for repairs and adjustments, and a final examination. To those autoists, however, who are accustomed to daily control periods of from seven to perhaps ten hours, the schedule of the Flag to Flag competition will be a surprise. From Eagle Pass to Torreon is a long run, and the schedule is five days and six hours for the largest cars, with additions of two hours each for the succeeding five sections; the next run is to Zacatecas, and two days and one hour is the time allowance. The third run can be figured out in plain hours and minutes, for it is to the City of Aguas Calientes, and the running time will be eight hours; then comes another long journey over the shifting roads, en route to the City of Celaya, with two days and 30 minutes schedule; the fifth control will be in the City of San Juan del Rio, with one day and 30 minutes; the sixth will be at the City of Tula, the schedule being another day and 30 minutes, and the final run must be made into the City of Mexico in seven hours and 10 minutes.

The classification has been changed somewhat in these rules, giving an extra division, the prices which separate them now being: $4,001 and over; $3,001 to $4,000; $2,001 to $3,000; $1,251 to $2,000; $851 to $1,250, and $850 and under. The daily schedule before reaching the border will give a 20-minute handicap over class 1 when the running time is nine hours or more, 15 minutes when it is between seven and a half and nine, and 10 minutes when it is less than seven and a half. In Mexico there is considerable difference in the allowance, given in detail in the regulations.

There will be a pacemaker from San Antonio, which will precede the tourists by one or two days. After leaving the United States a number of the regulations in regard to the operation of the cars will be changed. For instance, when tires have to be repaired the engine may be stopped, but there will be no penalty for work in connection with the pneumatics. Another alteration is that mufflers need not be carried, and still another is that if one contestant borrows parts from another contestant or a free-lance car in the tour, it will not be disqualified. When a machine reaches a control of more than one day's duration it may be immediately checked, and continue towards the next stop.

The problem of hotel accommodations is giving the managers some concern, for the plan to have a Pullman train accompany the travelers does not adequately fill the requirements, because for long distances the cars will be away from the railroads. The hotels in the various control cities are able to care for the party, but it would be necessary to camp out on the plains at times, and to carry sufficient food along. It has been thought best to allow those who will participate in the event to decide about the train or hotel arrangements.

Private Malcolm E. Parrott Receiving the Official Despatch at Governor's Island Prior to the Start

MILITARY MITCHELL BEGINS ITS TRANSCONTINENTAL TRIP

NEW YORK, Aug. 23—Bearing a despatch from Major-Gen. Leonard A. Wood, commanding the United States Army, Department of the East, to Major-Gen. John F. Weston, commander of the Department of California, the 1910 Mitchell "Ranger" started from this city for San Francisco on Thursday afternoon. Clad in the regulation army khaki, with canteens, haversacks and revolvers hung on the sides of the new touring car, were Private Malcolm E. Parrott, of the Tenth Regiment of the New York National Guard; Frank X. Zirbes as driver, and Lieut. B. B. Rosenthal, the three members of the party. With the plan of a definite schedule to follow, about 3,693 miles to cover, and probably much more, the new car is essaying one of the most strenuous trips ever attempted. No records will be aspired to, for the car will deviate from the direct route a number of times in order to visit army posts en route.

To New York automobiledom, however, there was wide interest in the Mitchell car itself, when it first appeared on Broadway. The entirely new line of the 1910 product of the Mitchell Company was a surprise, and General Manager Gilson was congratulated many times upon the pleasing style of the newcomer. The radiator, and consequently the hood, are materially different in shape from other Mitchells, and the alteration has included the body also. It was well prepared for the long journey before it, rope, shovel, pick and other tools being in the equipment.

Preliminary to the actual start was a trip to Governor's Island for the official despatch, and at exactly noon the party, acccompanied by a number of Mitchell cars from the Mitchell branch, and a delegation of private owners, assembled at Columbus Circle to witness the beginning of the rigorous jaunt. Private Parrott carried a large flag presented to him by Capt. W. L. Burnett, of his regiment, as well as the pennant of the Hudson Valley Automobile Club of Poughkeepsie, of which he is a member. The route selected is that most generally taken, via Albany, Buffalo, Chicago and Omaha.

LONG BRANCH RACES IN THE TWILIGHT

LONG BRANCH, N. J., Aug. 21—Lengthy delays, while horses were cantering up and down Ocean avenue this afternoon, interfered with what might have been a very successful series of one-mile straightaway speed trials. As it was, the cars did some high-speed work, but the hundreds of automobile parties from neighboring Jersey coast resorts tired of waiting for the start and returned to their homes. It was 5:45 P. M. when the automobiles were called to the tape, and they did not finish the heats until well into the dark, with their gas lights doing valuable service.

Some fast cars had been brought here for the event, among them being Heitemeyer's Simplex, Allen's Allen-Kingston, Rainier's Rainier, Roebling's Roeblink, Lescault's Palmer and Singer, and Burnham's Lancia-Fiat racer. The stock cars had matters their own way, in spite of the fact that there were a number of special types on the course. The Simplex took the honors of the evening for the fastest time, twice covering the mile in 52 seconds, a rate of 69.2 miles per hour, winning the $4,001 and over class, and the free-for-all. The big 120-horsepower Roebling was second in point of time, its record being :53, in the open class. Walter C. Allen's A-K captured the $3,001 to $4,000 division, in 55 seconds, with the P. & S. one second behind. Other class winners were: $2,001 to $3,000, S. P. O., 59 seconds; $1,251 to $2,001, Buick, 1:09; $851 to $1,250, Cadillac, 68 seconds. The A-K repeated its 55-seconds performance in the free-for-all, but a little behind the Simplex and Roebling.

CALIFORNIA TO HAVE 300-MILE RACE

SAN FRANCISCO, Aug. 20—It has been definitely decided that a 300-mile road race will take place during the three days of the Portola Festival. The date has been set for Saturday, October 23, and the event will be run over the Foothill Boulevard, near San Leandro. The Automobile Club of California will have the management of the event, and the supervisors of Alameda County have given their sanction to the event. The course is about 21½ miles long, having two long straightaways between which are many short turns. The cars will be divided into two classes, Class A of cars with greater than 300 inches displacement, and Class B for those under this measurement. The main trophy of the day will be the Portola Cup, which is valued at $5,000. The driver of the winning car in Class A will receive a purse of $800, the second best, $500, and the third, $300. In Class B the winner will get $250, the second, $150, and the third, $50. The winning car in this class also will be awarded a cup, valued at $1,000. Extrance fee will be $150, to be returned at start.

SECOND RUN AROUND LONG ISLAND

NEW YORK, Aug. 24—The second annual endurance run of the New York Automobile Trade Association around Long Island will be held on September 20, 21 and 22. The first night stop will be made at Shelter Island, the cars being parked at Greenport, and the second at Good Ground or Southampton.

LATEST NEWS FROM THE CAPITAL OF MOTORDOM

DETROIT, Aug. 23—When Henry Ford and his associates decided to purchase the old Highland Park racetrack and grounds, in the northern part of the city, and erect thereon what is said to be the largest single building in the world devoted to the manufacture of automobiles, wise ones in the industry shook their heads and averred that the Ford Motor Company had made a mistake in moving so far from the established manufacturing districts. Despite predictions of disaster, the Ford Company went ahead with the project, and now, just as it is moving into its new plant, comes the announcement that a new industrial district will be developed in the immediate vicinity, in which the automobile and its accessories will hold full sway.

Cramped for space in its present quarters that, at the outset, were considered adequate for all time, the Brush Runabout Company has purchasd twenty acres of land on the Grand Trunk Railroad, a short distance from the Ford plant, and work is already under way on four large buildings which will form the nucleus of a group that will eventually house all the local Briscoe enterprises, and may mean the addition of another large plant to Detroit's auto colony.

Frank Briscoe is president of the Brush Runabout Company, whose business has been growing at an enormous rate. Some time ago the Brush people transferred their business from the plant of the Briscoe Manufacturing Company, and now are compelled to put up a plant of their own, in order to meet demands. The Briscoe Manufacturing Company's trade in radiators, in which field it is one of the largest in the country, has grown to such proportions that larger quarters must be secured. The present plant will be added to, and it is the intention, as soon as the new Brush factory is completed, to start work on buildings for the Briscoe Manufacturing Company adjoining.

Quite the most interesting bit of gossip in this connection has to do with the establishment here of a factory by the Maxwell-Briscoe Company, which now has plants at Tarrytown, N. Y.; Providence, R. I., and Newcastle, Ind. Options are held on some forty acres of ground in addition to that already purchased, and it is known that the question has been discussed favorably by the Maxwell-Briscoe Company.

"Any definite announcement regarding such a move must come from my brother, Benjamin Briscoe, of the Maxwell-Briscoe Company," said Frank Briscoe in answer to an inquiry. "It is true that the matter has been discussed at length, and that Detroit has been looked upon with favor. Further than that, there is nothing to be said at present at this end of the line."

Associated with the Brush and Briscoe companies in the new district, it is understood, will be several parts and castings companies. The present plant of the Brush company will, under the new arrangement, be devoted to the manufacture of bodies.

A stock company, capitalized at $300,000 and with ample funds in reserve, has been formed to take over the business of the Blomstrom Motor Company, to continue the manufacture of Gyroscope cars. It is probable that the plant will be established in Adrian, Mich., as a majority of the stockholders in the new concern reside there.

FACTORY BUILDING OBSTACLES OVERCOME

Detroit, Aug. 23—Morgan & Wright's huge tire and rubber goods factory, located on the banks of the beautiful Detroit River, from the standpoint of scenery, light, air and water supply, is probably one of the finest factory sites in the country. It is doubtful, however, if these advantages, particularly the abundant water supply, appealed to the engineers in charge of installing the recent additions to the tire building equipment.

The steam presses in which the tires are cured are so ponderous that it is necessary to go down to bedrock to get a proper foundation for them. As the excavations proceeded below the level of the river, water oozed through into the shafts to such an extent that it was necessary to install a big centrifugal pump, and run it night and day to permit of continuing the operations. Even then the men were compelled to work up to their waists in water most of the time. In spite of these difficulties it is expected that the new equipment will be ready for operation inside of a few weeks.

SUGGESTS TIRE PUBLICITY AGREEMENT

Akron, O., Aug. 23—Anent the varied announcements concerning tire performance in the Glidden tour is a suggestion that hereafter the different makers unite on an agreed statement of facts before submitting their respective claims to the public. "We are willing to do that very thing," says W. B. Miller, secretary of the Diamond Rubber Company, "but we would want experienced tire men to keep the record and act as arbiters. We had on the tour this year four men who know all kinds of tires and tire mishaps intimately, and the result of their joint observations and inspections is supported by their affidavits; but another concern can come along with a different story, and there you are. Perhaps the public doesn't care particularly. Such things work out right in the end somehow, and nowhere more than in the automobile business. In no line of activity does the public more quickly bury false notions or so unerringly pick only the real gold from the unending glitter put forward."

INCREASING USE OF DEMOUNTABLE RIMS

Akron, O., Aug. 23—That fully one-third of next year's touring cars will be equipped with demountable rims is the prediction of H. S. Firestone in the latest news from large tire companies. The improved features of the 1910 demountables are of pertinent interest, and Mr. Firestone's contention is of special importance.

"The growth in popularity of these rims of late has been little short of phenomenal," says Mr. Firestone. "Three years ago they were known only to a few racing men; to-day thousands of private car owners have them. The improved features that appear in the latest rims permit their use with any standard type or make of tire, which means that no matter what may be the favorite tire chosen, the motorist can now enjoy the freedom from annoyance and delay which demountable rims offer."

Kentucky's Governor Honors the Glidden Lexington

The photograph shows Governor Wilson, at the State Fair Grounds, presenting the Lexington crew, which made such a fine showing in the recent Glidden Tour, with a gold watch to Driver Moore, and remembrances to Mechanic Blackburn and to Observer Dodge, all donated by the Lexington Motor Car Company, in appreciation of their services.

Banquet of the Stoddard-Dayton Agents, Held at Hotel Denison, Indianapolis, August 20, During Annual Convention

STODDARD-DAYTON AGENTS AND EMPLOYEES FACTORY GUESTS

INDIANAPOLIS, Aug. 21—Stoddard-Dayton is a name that has become exceedingly well known in this city during the past few days in connection with the opening of the motor-speedway. Not only because of the large participation of cars of this make was this so, but also because of the convention of the agents of the Dayton Motor Car Company, and of the excursion of the entire factory force to this city to-day. Then, too, none of the vast crowd which went out to the races could help seeing the special convention tent erected for the meetings, and at times the public became so insistent that the special exhibtion of 1910 Stoddard-Daytons had to be opened to them.

Inasmuch as the annual meeting of the factory representatives, to discuss the prospects for the coming season, was about due, the scene of action was shifted from Dayton to this city. The agents began to arrive on Wednesday and Thursday, and stayed throughout the race meet, with all their expenses paid by the Ohio firm. To cap the climax the entire factory force was brought here to-day in a special train of 17 cars. A corps of waiters and a chef were in attendance throughout the meet to serve lunches in the three private Stoddard-Dayton grand-stands.

The exhibition tent was an attraction in itself, for it was very large, and decorated to resemble an Italian pergola, covered with growing vines and flowers, with bey trees and junipers to carry out the effect. The result was that the whole appeared as substantially built as if intended to be permanent. Fifteen of the new models were grouped around the outer oval, giving ample space in the center for the morning sessions, and the exhibit was intended to be comparatively private. The crowds, however, were evidently so desirous of seeing the machines that they were allowed to inspect them. There was every style of automobile there, including roadsters, runabouts, baby tonneau, regular touring cars, a speed car and enclosed models of limousines, landaulets and coupes. The latter type attracted a great deal of attention, for the upholstering and details were elaborate and the whipcord, leather and broadcloth were used to their best advantage. A limousine of the 30-horsepower chassis was of particular interest, as was also an inside-driven coupe, which has its steering wheel, gear and brake levers so arranged that entrance can be made from either side with ease.

Two banquets were the features of Thursday and Friday evenings, on the former occasion the agents gathering around tables grouped in the shape of a U, and last night the letter S was similarly described. The autophone, an orchestra, and a military band took turns at furnishing the music.

The agents who attended were the following: Whitney and Ferris, Boston; Cramer, Buffalo; Babcock and Tillotson, Chicago; Church, Los Angeles; Hershede, Cincinnati; Moore, Cleveland; Jekins, Columbia; Roberts, Columbus; Dodds, Dayton; Barnett, Denver; Sears, Des Moines; Neumann, Detroit; Burington, Holyoke; McGee, Kansas City; Ward, Lexington; Longest, Louisville; Burmeister and Kelly, Minneapolis; Hartwell, Mobile; McShane, Newark; Wheeler and Westerfell, New Haven; Newton, Whiting, Percy and Warren, New York; Berren and Hamilton, Philadelphia; Fetill, Omaha; Moore and Jackson, Pittsburgh; Ziebrich, Rochester; Thompson, Salisbury; Holligan, Savannah; Thompson, Thomasville; Atwood, Toledo; Smith and Bonvier, Toronto; Lucey, Troy; Tool and Decker, Utica; Ide, Syracuse; Halff, San Antonio; Shellenberger, Wichita; Shoemaker, Elmira; Cox, Harrisburg; Schaab, Baltimore; Dorsett, Washington; Wallace and Dewitt, Chattanooga; Garret, Wilmington; Leavitt and Plughoff, San Francisco; Sherman, Salt Lake City.

CHANGES IN CLEVELAND WHITE BRANCH

CLEVELAND, Aug. 23—Several changes took place to-day in the Ohio retail department and local branch of the White Company, following the resignation of its manager, Hobart M. Adams. Frank E. Stiverson has been appointed to the position, and at the same time retains his former capacity as sales agent for this city and the State. Concurrent with this is the announcement by the factory officials of the consolidation of the repair and stock departments of the local branch and of the factory. Some confusion has been caused by White owners out of this territory getting in touch with the retail end of the business instead of the wholesale at the factory. H. N. Searles, who drove the kerosene-burning White steamer in the Glidden tour, will be in charge of the enlarged department and will be in direct touch with all owners and agencies from any locality. The changes in this city in regard to the Ohio territory do not directly affect the White representatives at Cincinnati, Toledo and Columbus.

The White plant is now working upon the 1910 product and shipments of the kerosene cars have been going on for some time, in quantities which promise one of the greatest seasons in the history of the concern.

Progress on Duplicate Addition to Chalmers-Detroit Factory, Detroit

Bowser Company Adds to Factory—Growth of the automobile industry has necessitated the addition from time to time of factory space at the plant of S. F. Bowser & Company, Fort Wayne, Ind., but none of the magnitude of the new building now under way. Up to the first of this year the Fort Wayne factory had 65,000 square feet of floor space, and the new structure will just double this. Work is progressing rapidly on it, and a contract has just been let for the installation of a 320-horsepower gas engine with a gas producer plant. The entire factory is working to the limit to supply gasoline and lubricating oil storage outfits for the automobile trade, in addition to that for the general demand. It also manufactures tanks, pumps and similar devices, as it was doing for fifteen years prior to the introduction of the automobile business.

Diamonds in Tire Mileage Record—A tire mileage record that many motorists will envy was made by G. W. Butler, who won first prize, $1,000, in the "lowest upkeep" contest conducted by one of the large automobile manufacturers. Mr. Butler is a chauffeur in the employ of J. E. Clenny, of Chicago, and his daily records were duly sworn to. The Diamond make of tires was used and in 17,003 miles covered gave an average of 11,289½ miles each, counting only the tires fully used up, or an average of 9,045 miles, including tires in use when the contest closed. A hint to automobile owners is found in Mr. Butler's system, by which when a rear tire had run 3,500 to 4,500 miles it was changed to the front, so that the newest tires were always on the rear.

Fine Building for Wintons in Seattle—What is claimed will be the finest automobile establishment on the Pacific Coast is being planned by the Winton Motor Carriage Company for Seattle. This will be erected at Pike street and Terry avenue, of steel and concrete construction, with a frontage of 80 feet and a depth of 120. It will have six stories, two below the street level and four above. The contracts have been let and the building will be ready for occupancy on January 1 next. The entire structure will be used by the Winton interests, for the rapidly increasing business in that city and the Northwest has far outgrown the present big quarters at 715 East Pine street.

Rushing Stearns Factory Addition—Under a forfeit of $100 a day, work is now being rushed on the new four-story brick and concrete addition to the F. B. Stearns factory in Cleveland, O. Under terms of the contract, machinery in the new building must be in running order by September 15. For the past year the Stearns factory has been badly cramped because of lack of room, the machine and forge shops being particularly hard pressed. The new addition, 120 by 180 feet, will materially aid the production department and provide for much quicker delivery.

An Ajax Transcontinental Record—In publicity matter issued by the Ajax-Grieb Rubber Company is the interesting tire report of the trip made by Mrs. Alice R. Ramsay across the continent in her Maxwell car. It is stated that three of the Ajax casing ran the entire 4,200 miles with the original New York air in them, and that but one puncture necessitated a change of the fourth, after several thousand miles had been covered. This is in line with the guarantee given by the Ajax company for 5,000 miles of running or 200 days of service with its tires.

Carriage Company to Specialize in Auto Bodies—The Carriage Woodwork Company, of Hamilton, O., has announced its intention of making a special feature of its work in automobile bodies. It has engaged William Cheetham, formerly of Detroit, to take charge of the construction department and to turn out both wood and aluminum bodies. Mr. Cheetham has had large experience in this line, having just finished a contract in Pontiac, Mich. He is a graduate of the Kensington School of Fine Arts of London.

Firestone Tires on Oldfield's Record-Breaker—At the Indianapolis Motor Speedway two of the fastest records set for an American special track were those which Barney Oldfield made for the mile and kilometer. On his car he used Firestone tires and set the mile record at 43.1 seconds, as against the 48.2, held by Jay on a regular track. The kilometer record for an American circular course is a new one, 26.2 seconds, a rate of 85.5 miles per hour. The Firestone Company is justifiably proud that its tires were used in such a meet on the big car.

Testing New P. & S. Motors—Experimental work and thorough tests of the new Palmer & Singer motors are now being carried out. Two new types of motors will be added to the already ample line of six and four-cylinder machines, and the preliminary work was held under the direction of Engineer David Landau. Mr. Landau states that one of the new engines will be able to furnish a speed of ninety miles per hour, and that the other type will have marvelous hill-climbing ability.

Bosch Gets Largest Magneto Order—The Bosch Magneto Co., of New York, announces that it has secured the order for equipment of Bosch magnetos on all Indian motor cycles for 1910. The Hendee Manufacturing Co., builders of this machine, has adopted the Bosch for its output next season, and the Bosch company states that the order exceeds by several thousand any similar one on record.

Addition to Parts Company Plant—The Illinois Automobile and Parts Company in Peoria, Ill., has had work started upon a $6,000 addition to its factory that will double its present capacity.

PERSONAL TRADE MENTION

Fred J. Titus has joined the sales force of the Palmer & Singer Manufacturing Company as assistant sales manager in charge of the out-of-town territory. He will begin his new duties on September 1. Mr. Titus is one of the best-known figures in the automobile trade and until recently had been connected with the Harry S. Houpt Company, leaving to enter the agency field in Newark, N. J.

O. L. Weaver, of Cincinnati, has resigned as manager of the branch of the Goodyear Tire & Rubber Company in that city and will locate in Cleveland as factory sales agent for Overland automobiles in eastern Ohio, western Pennsylvania and West Virginia. In severing his connection with the Goodyear Company he broke a service of ten years, six of which he had spent as manager of the Cincinnati branch.

Will S. Gilbert is now the automobile editor of the Cleveland *Plain Dealer*, succeeding Henry H. Hower, who has joined the Stearns forces. Mr. Gilbert was connected for many years with the Cleveland *Leader*, and is one of the veteran automobile writers. He covered the Glidden tour this year for the *Plain Dealer*.

A. K. Brown, of the Hoyt Electrical Instrument Works, Penacook, N. H., has been given charge of the Boston branch, 161 Summer street. He has been connected with the makers of the Hoyt instruments for a considerable time, thus being well equipped for his new position.

E. W. Carter, of the Hoyt Electrical Instrument Works, will hereafter be connected with the factory at Penacook, N. H. Mr. Carter has been in charge of the Boston office.

CHANGES IN THE BOSTON TRADE

Boston, Aug. 21—The crop of changes in the Boston automobile trade that comes every year about the time of the appearance of the new models has arrived, and recently there have been a number of shifts of interest. Prominent among them is the establishment of a branch house by the Thomas company. It is called the Thomas Motor Branch Co., and is in charge of Charles S. Henshaw who, several years ago, was the Thomas agent here. Just now the branch is located in upper Columbus avenue, but negotiations are in progress for a site in the Back Bay. For the past year or more the Thomas agency has been held by the Whitten-Gilmore Co., who now have the Chalmers and the Hudson agencies.

Another shift in local representation is the passing of the Algonquin Motor Car Co., agent for the Oldsmobile, and the organization of the Olds-Oakland Co. as selling agent for the Oldsmobile and the Oakland, two General Motors cars. The new concern has taken the Algonquin Motor Car Co.'s lease of the salesroom on Massachusetts avenue. On Boylston a new arrival is the Stevens Sowers Motor Car Co., which has the agency for the Jackson and the Fuller cars. The Selden Motor Car Co., of Massachusetts, is just opening a new store at 801 Boylston street, and the Continental Caoutchouc Co., heretofore represented by an agent, has a branch store about ready for business on Boylston street. The Panhard & Levassor branch, formerly on Massachusetts avenue, has moved to Dartmouth street, taking the quarters formerly occupied by the Goodyear Co. The Velie agency at 21 Hawkins street, formerly the Kilbourne-Corlew Co., has become the Corlew-Coughlin Co.

Two important real estate transactions marking the inroads that motor vehicles have made on the public carriage business were consummated lately. One of these was the sale of the large modern stable at Massachusetts avenue and Newbury street, formerly occupied by Kenny & Clark, livery and cab men, to F. J. Tyler, of the Maxwell-Briscoe Boston company. It is understood that Mr. Tyler will make the necessary alterations and soon the Maxwell-Briscoe sales, shop and garage headquarters will be established in the Kenny & Clark building. It is well located near Commonwealth avenue and the parks, most convenient for garage purposes and most conspicuous for sales.

Not far from the Kenny & Clark building on Massachusetts avenue is the large stable of the Boston Cab Co., which, by an arrangement made recently, is to be converted into a garage and headquarters for the Taxi Service Co.

Other changes in the local trade, including the placing of some new agencies, are said to be pending.

RECENT BUSINESS CHANGES

Lucia Brothers Change Firm Name—The Lucia Brothers Motor Car Company is the new name adopted by Albert J. Lucia and Howard E. Lucia, of Green Bay, Wis. Up to this time the Lucia Cycle Company was the firm title, but inasmuch as the automobile business is taking the entire attention the old name has been abandoned. The concern was started in 1888 with bicycles, and in 1900 automobiles were first taken up. A well-equipped garage and repair shop is maintained in Oconto, in addition to the headquarters in Green Bay.

Boston Taxicabs Companies Combine—The Taxi Service Company and the Boston Cab Company have arranged to work together, the former having purchased a substantial interest in the latter. For the present they will be operated separately, but without conflicts, and will later be merged. A. E. Morrison will continue as manager of the Taxi company.

TAXICAB AND TRANSIT

Dixon Springs, Tenn.—An automobile line has been established between Dixon Springs and Gallatin, a distance of 23 miles. At present but one car is being used, making the outbound trip in the morning and returning in the afternoon, connecting with trains to Nashville. If traffic requires it, another machine will be put into the service.

IN AND ABOUT THE AGENCIES

Baker, Chicago—The Baker Electric Vehicle Agency has leased for a term of ten years the property on Michigan avenue, 100 feet south of Twenty-third street. A building will be started at once, with the provision that it must be ready for occupancy on May 1, 1910.

Franklin, Pittsburgh—W. F. Reynolds, who was recently appointed manager of the new Franklin branch, has secured quarters at 5926 Baum street and will take possession on September 1.

NEW AGENCIES ESTABLISHED

Rambler and Regal: Charlotte, N. C.—Carolina Automobile Company, South Church street, E. A. Robbins, manager. Distributors for North and South Carolina.

Chalmers-Detroit, Hudson, Hupmobile: Natrona, Pa.—Plumer Eaton and Howard Humes, Second avenue.

American Simplex and Overland: Kansas City, Mo.—Louis J. Long and Clifford Histed, 1527 Grand avenue.

Jackson and Fuller: Boston—Stevens-Sowers Motor Car Company, 821 Boylston street.

Reo and Premier: Atlanta, Ga.—J. E. Levi & Co., 222-224 Peachtree street.

Peerless: Donaldsonville, Ga.—Louis A. Maurin.

Hudson: Trenton, N. J.—Harry B. Salter.

RECENT INCORPORATIONS

New Jersey Carbureter Company, Jersey City—Capital $25,000. To manufacture steel, iron, malleable iron, wood, and other carbureters, appliances, etc. Incorporators: Charles R. Nutter, F. L. Houghtaling, Charles F. Zissel, Jr.

Chicago Automobile Self-Starting Appliance Company, Chicago—Capital $70,000. To manufacture and deal in automobiles and accessories. Incorporators: C. E. Crane, Harry Hobbs, Charles Conlon.

C. A. Coey Automobile Service Company, Chicago, Ill.—Capital $200,000. To conduct an automobile livery and garage service. Incorporators: C. A. Coey, C. E. Gregory, D. Henderson.

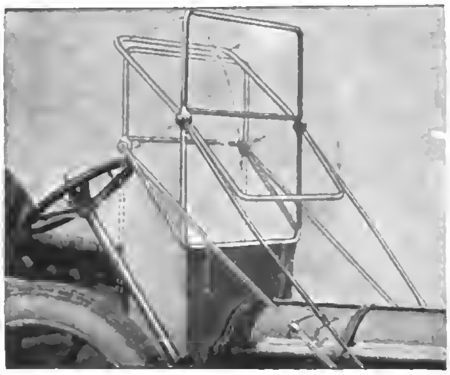
Harry S. Houpt Manufacturing Company, New York—Capital $600,000. To manufacture automobiles, motor boats, and aerial machines. Incorporators: H. S. Houpt, M. K. Harris, G. Cheney.

Parker Motor Company, Hartford, Conn.—Capital $50,000. To manufacture automobile engines, etc. Incorporators: Lucius F. Robinson, Albion B. Wilson, Francis W. Cole.

Group of Overland Automobiles in the Government Mail Service at Indianapolis, Taken in Front of the Postoffice

Information for Auto Users

The Friction Folding Wind Shield—This shield, of the centrally-hinged type, is capable of a great variety of positions, all of which are obtained without manipulating a single spring or thumb-nut, and with the use of but one hand. It is easily within reach of the driver when wanted, and may be quickly folded out of the way when not in use. No adjustments are necessary. The frame is made of



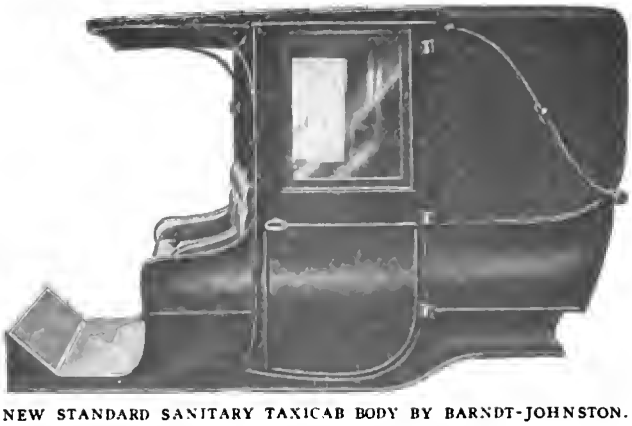
CENTRALLY HINGED TYPE OF WIND SHIEID

seamless brass tubing, with a sub-channel to hold the glass firm and prevent rattling. There are no sharp edges or corners to catch the dirt, so that it may be easily polished and kept clean. Its normal position for country driving is with the upper part folded down to the front at an angle of about 45 degrees below horizontal; this position greatly reduces the wind resistance, and the air currents are deflected over the driver's head. At the same time the glass does not interfere with his vision. The maker is the Newark Rivet Works, of Newark, N. J.

Barndt-Johnston Taxicab Body—The Barndt-Johnston Auto Supply Company, of Columbus, O., is furnishing various manufacturers with a new standard taxicab body, which embodies a number of up-to-date ideas. The body is made as sanitary as possible by the use of the skeleton type top and the substitution of linoleum for carpet as the floor covering. The framework of the body is of white ash, and the panels of sheet steel coated with aluminum. The rear portion is extremely large and roomy and will accommodate five passengers comfortably.

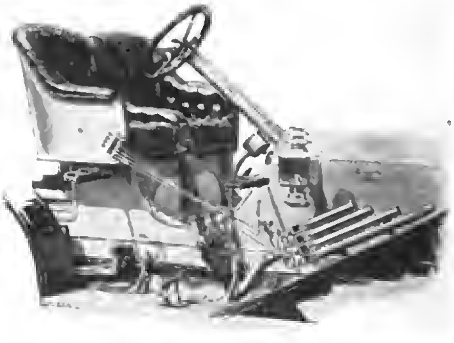
K-W Ignition and Lighting—To its line of magnetos and coils the K-W Ignition Company, of Cleveland, has added electric headlights and side lamps, intended to be operated by the current from one of their ignition magnetos. The lighting system is connected directly to the magneto, which may or may not be used for ignition purposes as well. Ignition requires about 25 per cent. of the current output of the magneto, consequently reducing to some extent the available amount of illumination; but even in this case it is claimed that the light is more powerful than that obtained from an acetylene system. When the motor is stopped the lighting, of course, stops too; but a storage battery is provided to supply current for the side and tail lamps, if required. The total battery consumption of these is about 3-4 ampere hours. The light also varies in intensity with the speed of the car, up to about thirty miles an hour, above which it remains constant. No matter how slow the car goes, however, there is always light enough to meet all requirements. There is no danger of burning out the lights at any speed; the regulation is automatic without governors or any other trappy devices.

The K-W line of electric lamps includes automobile headlights, side and tail lamps, speedometer lamps, dome and bracket lamps for closed cars, and searchlights and side lights for motorboats. The headlights are fitted with parabolic reflectors of brass, silver-plated, in which the electric bulbs are accurately focussed. The bulbs are of the tungsten type and very economical in their consumption of current. Fittings are also made by which gas headlights and oil side lamps may be converted to electric. One interesting feature of the K-W system is that if more light is required for a few seconds to make out some distant object, the clutch may be slipped momentarily, allowing the engine to speed up and doubling the illumination.



NEW STANDARD SANITARY TAXICAB BODY BY BARNDT-JOHNSTON.

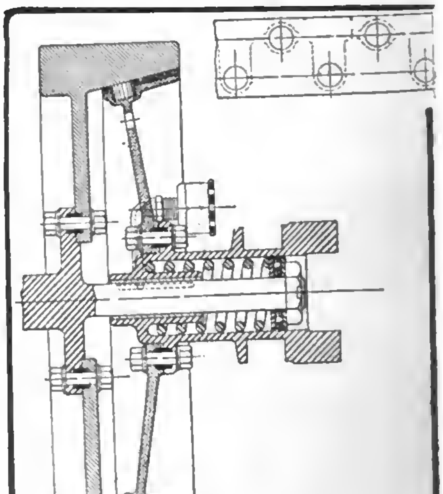
New Four-Tone Horn—That prolific inventor, C. H. Foster, of the Gabriel Horn Mfg. Co., Cleveland, has just brought out another clever little appliance for the automobile, which is destined to be just as popular as his previous devices are. This is a very small, compact horn of four tones, suitable for playing bugle calls and similar simple tunes, through



NEW GABRIEL HORN IN PLACE ON CAR

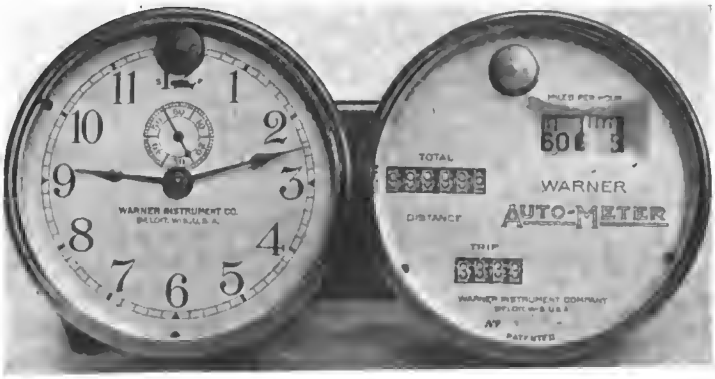
the medium of the exhaust gases. It is operated by a keyboard comprising four keys, each controlling one note, and the whole located on the side of the seat, convenient to the driver's right hand. In addition, a foot pedal, when pressed, sounds all four notes at once, this serving as a warning signal. While any location is possible, the usual place is that shown in the cut above, on the front running board, just back of the front fenders.

General Cone Clutch—A revival of the interest in cone clutches, which has been so noticeable in connection with the most recent car production, is accounted for in a wide measure when notice is



CORK INSERT CONE CLUTCH FROM INDIANA

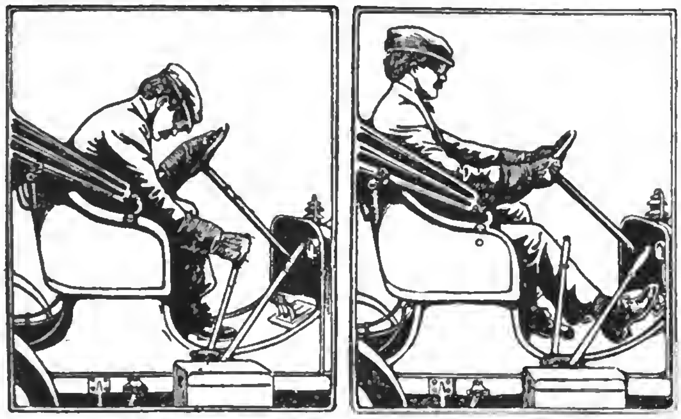
taken of the line of cone clutches that are to be had from the General Manufacturing Company, of Elkhart, Ind. Of the several sizes and models of cone clutches which this company is furnishing to makers of cars in large quantities, the type F size, rated at 30-35 horsepower, is here illustrated and, as will be observed, it is leather-faced with "cork inserts" and up to the standard established by the National Brake and Clutch



WARNER'S NEW TWINS AS THEY APPEAR FACE TO FACE

Company, originators of "cork inserts." In addition to the cork, with a view to bringing the leather to a good bearing springs are placed at equal distances around the periphery, under the leather, so that the leather is pressed out evenly against the female member of the clutch. The General Manufacturing Company is manufacturing a full line of these clutches, in addition to transmission gear sets of the latest and most approved types for use in 1910 cars.

F-B Automatic Clutch Release—All owners of the Buick Model 10 will be interested in a device brought out by the F-B Company, of Columbia, S. C., known as the F-B automatic clutch release. Its purpose is to enable the driver to release his high-speed clutch without stooping over to reach the lever. This is accomplished by interconnecting the service brake with the clutch, so that when the brake is applied the clutch is released, and when the brake is taken off the clutch automatically engages again. The result is the same as if the car were fitted with a sliding gear and master clutch. The device has been on the market for some time, and many letters of commendation have been received.



METHOD OF OPERATION OF F-B AUTOMATIC CLUTCH RELEASE DEVICE.

As the two cuts show, the old way of releasing the clutch was an awkward one, resulting in a cramped position and the loss of much time in reaching for the lever. This device does away with all that, allows better control, a clear view ahead and eliminates the stooping forward action.

One New Idea from Cincinnati—This southern Ohio city has gone into the motoring field with a new accessory especially designed for automobiles. This is a dry battery, known as the Sparker, and its manufacturers, the Rock Island Battery Company, Cincinnati, are exploiting it as an extra special ignition dry cell, and the highest priced cell on the market as well. This battery differs from others in that Japan is the source of the manganese ore used, instead of Russia. Other points of difference are the high voltage and comparatively high amperage peculiar to the cells. It is a hand-made cell and the result of three years of experimentation and successful use. Made in every size for which there is a demand, the most popular 2½ by 6 size, known as No. 6, retails at 35 cents. Other larger sizes are priced in proportion. The well-sustained electromotive force makes it worth every cent of its cost, high as it is.

Separate Department for Automobiles—One of the largest of the many large metropolitan supply houses, that of the New York Sporting Goods Company, 15 Warren street, has had its automobile supply department expand to such an extent that the necessity arose for segregation. So it is that the basement and first floor have been given up to supplying motorists' wants. Chains, oils, batteries and other heavy goods of a similar nature will be located in the basement, and above them, on the first floor, will be found clothing lamps, horns and the smaller parts. Located just one door from Broadway, in the heart of the downtown district, this store will be found very convenient.

Warner Autometer "Twins"—No mechanical change has been made in the 1910 Warner Autometer, but a new combination autometer and clock has been brought out, called "The Twins," very attractive in appearance. As may be seen from the illustration, the clock and the speedometer-odometer device are each in a cylindrical case exactly similar in size and shape, thus giving the instrument an appearance of symmetry very pleasing to the eye. The dials are illuminated from the interior, the light being thrown directly on their backs, and so arranged that it does not interfere with the vision of the driver. As most autoists know, the Warner Autometer, which is made by the Warner Instrument Company, of Beloit, Wis., is built on the magnetic induction principle. Chronometer construction is followed, the moving parts running on sapphire jewels and balls. The driving shaft is designed to turn at one-fourth the usual speed, that is, at 680 revolutions to the mile, thus giving it long life and eliminating noise and vibration. The odometer is built with the same care; its trip and season dials register up to 1,000 and 100,000 miles, respectively.

With improved roads, automobile speeds are gradually increasing, and this device will meet with a wide range of usefulness among the motorists who think, in the words of a Warner competitor, "it's nice to know how far you go," the modern version being "it's nicer to know how fast you go." The new twins allow for the first time the record of time, distance and speed at one and the same time.

THE AUTOMOBILE

NEXT LOWELL'S NATIONAL STOCK RACES

Where the Storm Center will be Located

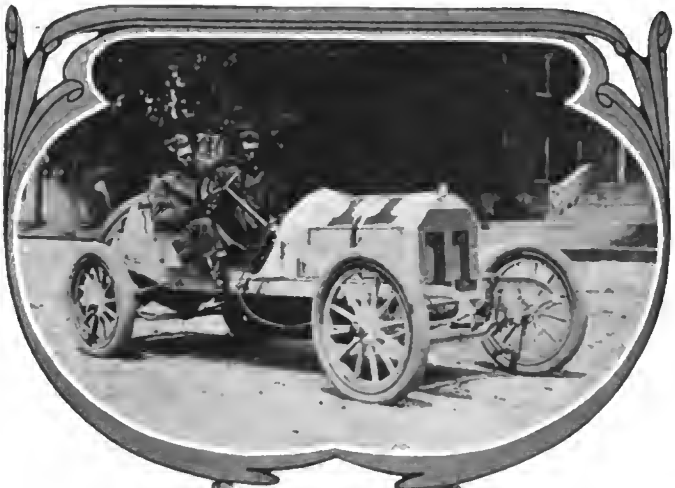
Hustlers Heinze and Hower

LOWELL, MASS., Aug. 31—If conscientious preparation and a generous entry list insure success, then there should be no question of most satisfying competition in the A. A. A. national stock car races to be held next week under the auspices of the Lowell Automobile Club.

The Merrimac Valley course is 10 6-10 miles long, and the only fault that might be found is in the fact that it is for the most part composed of ideal boulevard roads which will permit of exceptional speed. Under the capable leadership of John O. Heinze, the Lowell club has prepared for the racing in no prodigal manner, but with a thoroughness that has not taken into account the question of expense. Chairman F. B. Hower of the A. A. A. contest board has been very much on the scene, while the near presence in Boston of President L. R. Speare of the A. A. A. has been another advantageous situation. The representative entry is sufficient to guarantee gilt-edge sport, and the presence of enormous crowds is a certainty with a course in such close proximity to an over-populous area.

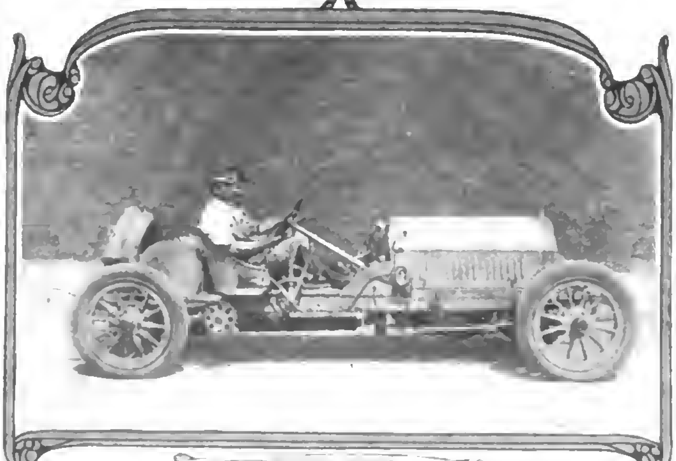
The little cars will open the competition on Monday, followed by mixed straightaway trials on Tuesday, with Wednesday devoted to the big car event. Motor boat races will occupy Thursday morning, with a Marathon foot race in the afternoon, and on Friday the meet will conclude with the motorcycle events.

That there will be speed in plenty is generally recognized, for the stock car of to-day is the equal, in available power, of the racing craft of earlier and more unrestricted days. The intent of the manufacturers interested in racing is to limit competition to cars of which the duplicates can be found in the salesroom



Moon, Yorick Cup — Davis, Driver

Benz Vesper Trophy — Stoecker, Driver



Alco Lowell Cup — Grant Driver

by the man who selects because of ability demonstrated in racing. While it is true that the rules at present require some revision, the progress made in this direction in the past year has been decidedly substantial.

How the Various Competitions are Scheduled

From the looks of the entry list and the events scheduled, this will probably be the greatest automobile road-racing event of the year. The classes represent the fastest American and foreign cars of the "stock chassis" types. Only classes 1 and 2 will have foreign cars. Of the eighteen machines in class 1, only three are not native, the foreign representatives being the Isotta and two Fiats. In class 2 are the Benz and the Renault, the former being rather a "dark horse," as that size of Benz is scarcely known in this country.

The list of events and the days of their running are as follows:

MONDAY, SEPTEMBER 6

Class 2—Vesper Club Trophy—For all cars having a piston displacement between 301 and 450 cubic inches. The minimum weight limit for this class is 2,100 pounds. The distance will be twenty laps or 212 miles.

Class 3—Yorick Club Trophy—For all cars having a piston displacement between 231 and 300 cubic inches. The minimum weight limit for this class is 1,800 pounds. The distance will be fifteen laps or 159 miles.

Class 4—Merrimac Valley Trophy—For all cars having a piston displacement between 161 to 230 cubic inches. The minimum weight limit for this class is 1,500 pounds. The distance will be twelve laps or 127 2-10 miles.

TUESDAY, SEPTEMBER 7

Mile Straightaway Trials for high-power machines.

WEDNESDAY, SEPTEMBER 8

National Stock Chassis Competition for cars in Class 1—Lowell Trophy and $2,000 cash—The cars in this class are limited by a cylinder capacity varying from 451 to 600 cubic inches. The minimum weight limit for this class is 2,400 pounds. The distance will be thirty laps or 318 miles.

THURSDAY, SEPTEMBER 9

Motor Boat Races in the morning, and a Marathon foot race in the afternoon.

FRIDAY, SEPTEMBER 10

Motorcycle racing with six events will be run off.

Without doubt, the third day's racing will prove the representative road competition event of the season. The foremost cars and drivers are involved, among the drivers being such well-known ones as Robertson, Strang, Lytle, De Palma, Chevrolet, Burman, Cobe, Poole and Parker in the big car class. In the small cars will be Dingley, Matson, Lorimer, Jelnaw and Knipper, all of whom will drive Chalmers "Blue Birds"; while Chevrolet, Burman, DeWitt and Ryall will handle Buicks; with See, Sickinger and one yet to be named, as a Maxwell trio. Basle will have a small Renault.

The events are scheduled to start at 10 o'clock in the morning every day except Tuesday when they will not begin until 2.30 p. m. In the long races Monday and Wednesday, the cars will start at half-minute intervals, and on the opening day the smallest class will be started first; that is, class 2 will start before class 3, with class 4 last. It is expected that the classes will finish about the same time.

Numbers Were Drawn on Monday

The numbers for the order of starting were drawn this noon, the drawing taking place in the clubrooms, which are in the Richardson Hotel. This is also the official headquarters for the A. A. A. and of the meet. Those present included Chairman F. B. Hower of the A. A. A. contest board; Secretary E. L. Ferguson and Fred Wagner, the official starter. To the secretary of the local club, J. A. McKenna, fell the lot of drawing the numbers which decided the starting position of the cars.

Special numbering will serve to distinguish each class. To class 1 belong all cars numbered from 1 to 20. Class 2, since it contains more than ten cars, has necessitated the use of letters: hence the cars are designated by letters from A-2 to K-2. All class 3 cars will have numbers in the 30's, while those which belong to class 4 will be identified by being in the 40's. Thus the class and the car can be quickly and conveniently determined at its approach. One unusual feature of this race which should be mentioned, is that it will be run clockwise instead of counter-clockwise, as usual. Following is the official entry list, together with the order of starting:

SMALL CAR RACE—THREE CLASSES
Monday, Sept. 6

CLASS 2—VESPER CLUB TROPHY: For cars of 301 and including 450 cubic inches piston displacement; minimum weight of car, 2,100 pounds; distance, 20 laps (212 miles); entry-fee for each car, $300; additional prizes: $600 to winner, $200 to second, $100 to third, in cash or plate.

No.	Car Name	Driver
A-2	Chalmers-Detroit	L. B. Lorimer
B-2	Stoddard-Dayton	Burt Miller
C-2	Knox	
D-2	Acme	
E-2	Benz	
F-2	Renault	Charles Basle
G-2	Buick	Louis Chevrolet
H-2	Chalmers-Detroit	Burt Dingley
I-2	Stoddard-Dayton	B. W. Shaw
J-2	Buick	Bobby Burman
K-2	Knox	Fred Belcher

CLASS 3—YORICK CLUB TROPHY: For cars of 231 and including 300 cubic inches piston displacement; minimum weight of car, 1,800 pounds; distance, 15 laps (159 miles); entry-fee for each car, $300; additional prizes: $600 to winner, $200 to second, $100 to third, in cash or plate.

No.	Car Name	Driver
30	Columbia	John J. Coffey
31	Buick	George De Witt
32	Atlas	
33	Buick	Lewis Strang
34	Moon	Geo. Davis

CLASS 4—MERRIMAC VALLEY TROPHY: For cars of 161 and including 230 cubic inches piston displacement; minimum weight of car, 1,500 pounds; distance, 12 laps (127 2-10 miles); entry-fee for each car, $300; additional prizes: $600 to winner, $200 to second, $100 to third, in cash or plate.

No.	Car Name	Driver
40	Buick	Arthur Chevrolet
41	Maxwell	Wm. Sickinger
42	Chalmers-Detroit	Wm. Knipper
43	Buick	Jimmie Ryall
44	Maxwell	Arthur See
45	Maxwell	
46	Chalmers-Detroit	J. M. Matson
47	Chalmers-Detroit	Frank Jelnaw
48	Velie	

NATIONAL STOCK CHASSIS RACE FOR THE LOWELL TROPHY
Wednesday, Sept. 8—Distance, 318 Miles

Open to any "stock chassis" of 451 to and including 600 cubic inches piston displacement; minimum weight of car, 2,400 pounds; entry-fee for each car, $400. The length of the course shall be 10 6-10 miles, which shall be covered thirty times, making the total distance of the race 318 miles. In addition to the trophy, cash prizes will be awarded as follows: To winner of first place, $1,000; to winner of second place, $500; to winner of third place, $300; to winner of fourth place, $200.

CLASS 1

No.	Car Name	Driver
1	Buick	Lewis Strang
2	American	
3	Allen-Kingston	Hugh Hughes
4	Buick	Bobby Burman
5	Alco	Harry F. Grant
6	Isotta-Fraschini	A. J. Poole
7	Fiat	E. H. Parker
8	Knox	Fred Belcher
9	Stoddard-Dayton	Burt Miller
10	Knox	
11	Fiat	Ralph De Palma
12	Simplex	George Robertson
14	Knox	
15	Stoddard-Dayton	B. W. Shaw
16	Apperson Jack Rabbit	H. H. Lytle
17	Buick	Louis Chevrolet
18	Lozier	Harry H. Cobe
19	Stoddard-Dayton	

Great Preparations for the Race

Much credit is due to the Lowell Automobile Club for the efficient preparations which they have made so far or have under way at present. The grandstand is practically finished, and is an enormous affair. The road for more than a mile on either side of the stand is fenced with heavy wire, and both turns at Dunbar avenue are guarded in such manner that the cars can go fully fifty feet off the road before reaching the barricade.

On the day of the race it is hoped that the militia will be permitted to wear their uniforms. Five hundred soldiers and a hundred flagmen will keep the 10-6/10 mile-circuit clear.

The southern side of the course is State boulevard and is a fine macadam road. This has been treated with an asphaltum composition which is in good condition for practice and should be excellent by the time of the final races. On the northern side is a short stretch of macadam; otherwise it is ordinary dirt road. The improved road will soon be tarred, and the dirt section has already received a coat of calcium chloride, which effectually lays the dust. The steam rollers are now going over it finally to put it in the best possible condition. Not only has the club gone to the expense of treating the roads with dust-laying solutions, but

The Maxwell Runabout Trio

Dingley, Matson, Knipper, Lorimer, Jelnaw

Chalmers-Detroiters At Home

Pontoon Bridge Across the Merrimac River

they have gone so far as to cut down the top of one hill so that the descent will not be so abrupt. The hill is called the "Dip," and it is probably the worst place on the course. There is a very steep declivity, followed by a turn at the bottom. The road has been filled in until the part in the valley is fifteen or twenty feet above the creek which flows in the bottom. Along the edges of this narrow filled-in road are large heavy boulders, which will easily put any car out of the race that may skid into them, even if it does not go off of the road.

The grand stand is one of the best that has been erected at any American race. It is built in eleven sections, each of which is ninety feet long and contains seventeen boxes and seats for five hundred persons. Thus there will be accommodations for nearly 6,000 people. The entrances are from a covered walk which is under the grand stand and are of the type similar to those in the Harvard Stadium. An electric-lighted pontoon bridge has been built across the Merrimac river near the stand, so that spectators may reach the course from the trolley cars. To remove any possibility of accident to the officials and press men, a suspension bridge has been erected across the course between the judges' stand and the main stand.

Several other bridges have been put across the course at other places for the convenience of pedestrians, while across Dunbar avenue a heavy bridge has been built so that cars can reach the inside of the course without having to cross the track.

At the hairpin turn, which is at the western end of the course, the road has been widened, and a tree which grew at the center of the junction of the two roads has been removed. The only other turns of account are those from Varnum into Dunbar avenue, and from Dunbar into the boulevard. These are both rectangular, and they are to be cemented, so that the skidding will not tear them up excessively and so that there will be a wider road into which they may skid.

Where the New Dirt Road Was Made Connecting Burman Avenue and the Boulevard

Some of the Cars at Practice

Only a few of the teams had reached the circuit on Tuesday. Those which have arrived have found nearby quarters. The Chalmers team have two farmhouses on the backstretch. This team was one of the first on the course, and both Dingley and Lorimer have made a few practice runs over the course. Matson would have done so this morning had he not had the accident. Knipper and Jelnaw, his teammate, had to go around in touring cars, as their cars have been delayed on the road somewhere. The early arrival at the course of the Chalmers team is deemed significant by those who know, and a duplication of victories at Crown Point and in the Jericho Sweepstakes are predicted.

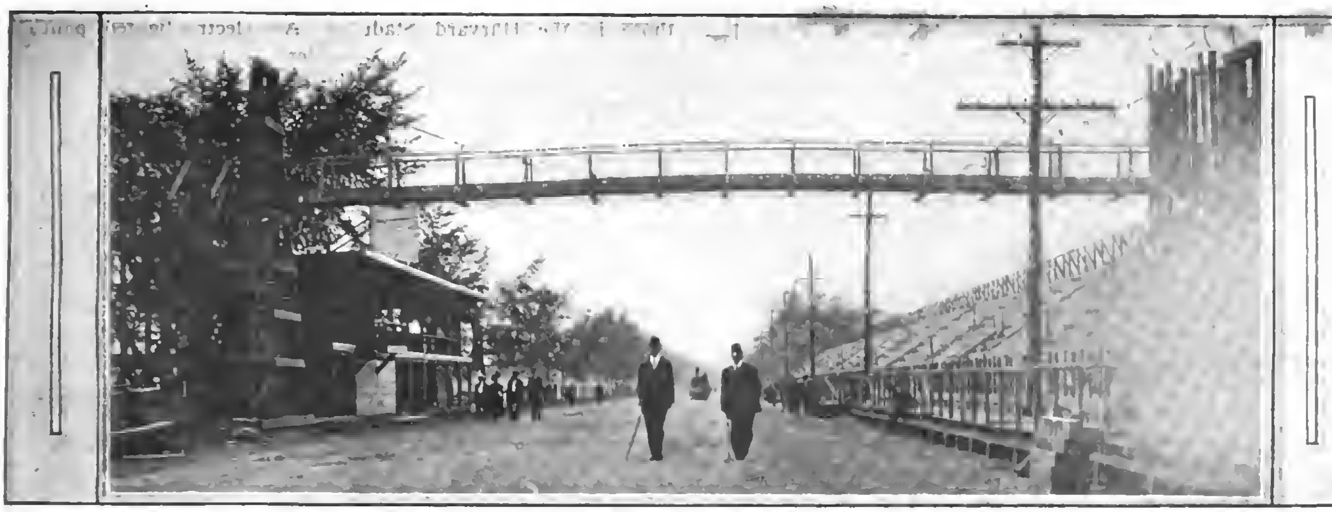
"Herb" Lytle, who is driving the Apperson, is much feared in his class, and has arrived early in order to profit by practice, if that can help to win a race.

Another contender who has been trying the circuit is Hugh Grant with the Alco. This car is practically a duplicate of the car which did so well last year over this course. Grant has the greatest confidence that he will do still better this year.

Among to-day's arrivals was Al Poole, with the Isotta and exactly similar to the car which last year won the Lowell trophy and also won the Savannah and Briarcliff cups. Last year Strang drove the car, but this year he will drive a Buick. All the Buicks have not arrived as yet. Only one has been on the course thus far.

In the second class there is considerable apprehension over the Benz entry, which is really a "dark horse," as no Benz cars of this size have been raced in this country. If the small car does as its bigger brothers have done in Europe, and in the Savannah race last year, there is little hope for the other contenders.

Mrs. Bert Dingley, Mrs. Joe Matson, Mrs. Harry Bill



On the Track at the Grand Stand, Where a Bridge Permits Safe Passage Over the Course

The driver, Stoecker, is scarcely known in this country, but has a series of victories in Europe to his credit.

The Maxwells and the Stoddard-Dayton driven by Bert Shaw are the only others who are on the course so far to-day. The next couple of days should see the remainder of the teams on the course.

Maxwells will be represented in the light-car contest by three of the latest production, the Model Q. This is the four-cylinder car of 22-horsepower, just announced for delivery. The cars have been in a number of events, notably hill climbs, and have given splendid accounts of themselves.

Following its custom at big races, the Maxwell-Briscoe Company has arranged for the use of 20 acres of land belonging to the Butterfield farm, and this space will be thrown open to Maxwell owners. There will be ample parking space thus assured for all who tour to the carnival in this make of automobile.

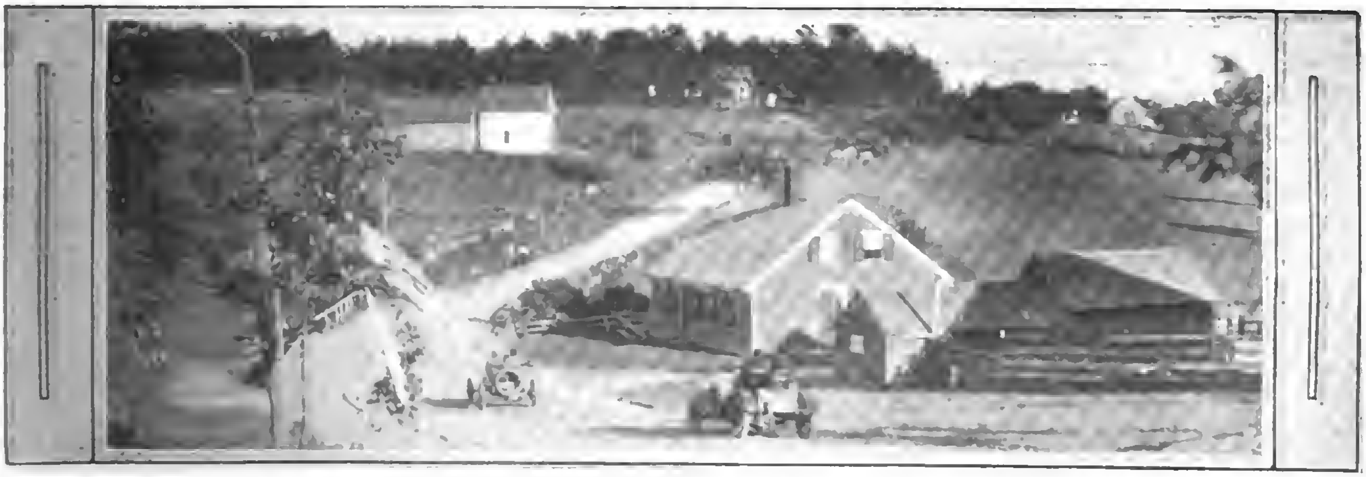
The Moon car, which will be driven by Harry Davis, in the competition for the Yorick cup, is the same stock roadster which was entered in the Indiana light-car race, and there secured fourth place. Previous to that it had been in another road race, and there won second place, driven by Harold Brinker. This latter was the Denver road contest, in which he made a run from a position near the rear right up to the second place.

One of the late cars to be entered will undoubtedly be a strong favorite, both because of itself and of its driver. The machine is a 50-horsepower stock Simplex, and it will be handled by George Robertson. This model is the one used by Robertson in winning a number of victories in stock-car events, notably two recent 24-hour races, and in one of these establishing the world's record of 1,177 miles. It will be seen next week in the big race on Wednesday.

One Unfortunate Fatality in First Practice

LOWELL, MASS., Aug. 31—Much to the regret of all concerned the practice opened to-day with a fatality, and this happening has cast a gloom over the few drivers already on the course. This morning the Chalmers, driven by Joe Matson, just as he was going to practice, struck and fatally injured a boy on Varnum avenue. No blame, however, is placed on Matson, as he did everything in hi power to prevent the accident. So violently did he apply the brakes that the differential and wheel clutches were entirely destroyed. Reliable reports state that the boy tried to run across the road, and seeing the machine approaching, lost his head and remained rooted to the spot. Matson tried to avoid him, but just before the car reached him the boy jumped directly in front of the machine. The radiator of the car was demolished, so severe was the impact. As a result of the accident, Matson is now under a $2,000 bond.

A petition for an injunction to prevent the holding of the races was filed to-day in the Superior Court. The attorney, E. J. Tierney, represents Mrs. O. A. Gray, an owner of real estate along the course, who claims that her property will be damaged by the speeding autos. It was claimed that the act of the Legislature permitting the event is unconstitutional, and Judge Dana issued an order of notice, returnable on Thursday. The complaint is directed against the Lowell Automobile Club, the officers of which are not inclined to believe the injunction will be made permanent at this late hour.



Deep Dip on the Back Stretch, Which Is the Most Dangerous Part of the Whole Course

H. O. SMITH ON GLIDDEN TOUR PROTEST

NEW YORK, Aug. 31—In order to make plain the reasons for his protest in connection with the Glidden tour, H. O. Smith, president of the Premier Motor Mfg. Company, has issued a statement wherein he aims to show that if the rules were properly enforced there would be no question about the Glidden trophy going to the Premier. He has declared himself as follows:

"I have been in hopes that the chairman of the Contest Board of the A. A. A. would give out full information, setting forth the conditions surrounding our protest at the conclusion of the Glidden tour, and it is evidently the failure to do this which has occasioned our receiving requests from so many sources to give full facts regarding the protest, which I am satisfied, to avoid a general misunderstanding, the public should know.

"The Premier Company regrets the necessity of making a protest on a point which on the surface might seem so trivial, but a number of cars have proven so good that only small points of vantage could be found by the technical committee at the conclusion of the strenuous run as the basis for determining awards.

"However, this contest was run under stated rules, and the rules specified under "Qualifications," paragraph No. 5:

> Cars shall at all times during the tour carry mufflers and guards, and be fully equipped as per manufacturers' catalog specifications, except that tops and wind shields need not be carried.

"The two roadsters of the same make as the car which was awarded the Glidden trophy, which carried their lamps attached in the same manner as provided on the touring car of that make, suffered in consequence on account of the bad roads, by one having a bent bracket and a badly crushed lamp and the other by having the receptacle in the rear to which the lamp and bracket is attached entirely dragged off.

"The failure to carry lamps was in itself a violation of the rules," continues Mr. Smith, "and, judging by the experience of the roadsters of this make which carried the full equipment, it is fair to assume that the touring cars which did not carry this equipment the entire distance escaped at least as much damage as was done to these two roadsters, and an official report of the penalties shows that the roadster of this make, No. 109, with a total of 10.2 points, was charged, among other things, for replacing tool box, bracket and taillamp, 3 points for time; bracket, 1.2 points for material; taillight, 3.2 points for material; while other cars in the contest were charged for lamps and brackets, and in addition one or more cars were compelled during the technical examination to light their oil lamps to show that they were in good going condition."

In conclusion Mr. Smith says: "Since the Premier car conformed to the rules, and made a perfect road score, and at the conclusion suffered a penalty of only one and a half point, on account of broken spring clip and reapplying fan belt, a proper charge for lamp only would alter the final score and make the award favorable to the Premier."

DETOUR ON ALBANY-PITTSFIELD ROUTE

ALBANY, N. Y., Aug. 30—Secretary Martin of the Albany Automobile Club advises tourists going from Albany to Pittsfield or vice versa of a detour necessary from the village of East Schodac to Nassau, a distance of five and a half miles, due to the reconstruction of the road. The Albany club has erected signs showing a serviceable route around the closed section. With this exception all of the roads on the Albany-Pittsfield route are in excellent condition.

MITCHELL ARMY CAR ON THE PRAIRIES

Carrying army dispatches from New York to San Francisco, the Mitchell Ranger, which left the former city on August 19, is now on the open prairies of the West. It reached Chicago on the following Tuesday, and proceeded on the next day to reach Iowa. That State was crossed during the remainder of the week, and Nebraska entered. Latest reports locate the machine near the Wyoming line.

CORONER BLAMES TRACK MANAGEMENT

INDIANAPOLIS, Aug. 28—Blame for the accidents that occurred during the recent race meet at Indianapolis, resulting in the death of five persons, has been placed on the management of the Indianapolis Motor Speedway by John J. Blackwell, coroner of Marion county.

Of the accident that occurred when the National car driven by C. C. Merz bursted a tire, killing Clyde Kellum, the machanician, and two spectators, the coroner says:

"I find that the protection of the spectators and the public who paid their admission fee to see the races was very lax. There was no discipline among the guards and soldiers stationed there to guard the public from danger. I find also that there were danger signs and placards around the track and the Indianapolis Motor Speedway Company knew the dangerous condition that existed there and should have afforded the public more and better protection from death and accident."

In his verdict relative to the deaths of William A. Bourque, driver of the Knox entry and his mechanician, Harry Holcomb, the coroner stated that he expected to recommend that the accident be investigated by the grand jury.

In preparation for the next meet, to be held in October, the Speedway management is planning to resurface the track with bitu-mineral paving material, and changes will also be made in the rearrangement of the private grand stands to assure greater safety.

WINNERS, STEAM AND GASOLINE WHITES

CHICAGO, Aug. 30—The second annual gymkhana was held at the Wheaton County fair, Saturday, under the management of a committee from the Chicago Motor Club, and a White steamer driven by Paul Melchert was returned the winner, with a White gasoline car handled by G. W. Turgeon second. J. H. Seek's Premier was third, a Silent Knight Daimler fourth, Diamond T fifth, Falcar sixth, Overland seventh, Austin eighth, Peerless ninth, Buick tenth, Columbia eleventh, Halladay twelfth, De Tamble thirteenth, and a Knox fourteenth. The gymkhana was made up of five sections, starting with an obstruction race in which the driver carried a glass of wine and steered with one hand; then came the motor roulette, circus ring, lancers and the teter board. On the last-named just half the cars succeeded in balancing. This was the first public appearance in Chicago of the White gasoline car and the Daimler, the latter being an English machine.

JACKSON COMPANY SUES FOR CUP

INDIANAPOLIS, Aug. 30—The Jackson Auto Company has filed suit against the Indianapolis Speedway Company and the Wheeler-Schebler Company for possession of the $10,000 cup offered by the latter company to the winner of the 300-mile race. A Jackson car was in the lead when the race was stopped at 235 miles because of the accident that caused the loss of three lives. The Jackson people also sue for $100,000, which amount of damage they claim has been done them through the withholding of the prize. Just what action the Speedway Company will take is not stated. The A. A. A. officials decided upon a "no-race."

BALTIMOREANS WILL USE PLENTY OF OIL

BALTIMORE Aug. 30—Street Cleaning Commissioner Wickes says that with his experiment of laying the dust in the city streets with oil, he has at last mastered that evil, which has been for years a bane to Baltimoreans. This process will be in constant use hereafter. The Commissioner has also been experimenting with oil on the macadam roads within the city limits with the view of saving the roads from the havoc wrought by autos, and he says that he finds the oil scheme the best preventative. The result is that he has advocated oil-covered macadam roads for all residential sections of the city.

Brilliant Scene at the Start of the Round-the-Clock Grind, with Ten Fine Cars in the Line-Up

RENAULT WINS FATAL BRIGHTON TWENTY-FOUR

NEW YORK, Aug. 28—Many accidents, one doubly fatal, distinguished the second Brighton Beach twenty-four-hour race conducted by the Motor Racing Association this season. Shortly before midnight Friday the Stearns driven by Grosso collided with Patschke's Acme on the clubhouse turn. Grosso was mortally injured and Leonard Cole, his mechanic, was killed outright. The Acme crew was uninjured. Grosso died Sunday morning without recovering consciousness.

The Renault driven by Basle and Raffalovitch won with a score of 1,050 miles, 41 miles behind Robertson's performance in the July race, and 127 miles behind the record. Rainier, again a consistent performer, finished second with 938 miles; Acme No. 3, driven by Patschke, took third with 883 miles, and Palmer-Singer, Allen-Kingston and Acme No. 4 finished in the order named. Lozier, Fiat and Stearns were eliminated by accidents, and Houpt dropped out early in the race. Michelin tires were used on first and second cars.

The start at 10 P.M., Friday night, afforded the usual picturesque features, and was attended by a record-sized crowd. The association's repeated prediction of a record-breaking entry again proved unfounded, as but ten machines lined up for the starter's pistol. De Palma and his Fiat got away in the lead, and finished the first five miles in 5:32 3-5. Patschke in Acme No. 3 led at the end of the first hour, and his score of 55 miles proved sufficient to win him the $200 prize for the best hour. Van Tine's Acme No. 4 made the same distance in a few seconds more.

Then the acccidents began. The Allen-Kingston lost a rear tire on the upper turn and was struck by the Fiat. The impact burst the gasoline tank of the A-K, and instantly the car was enveloped in flames. Hughes and his mechanic leaped from the car, blazing like human torches, and rolled in the grass of the infield. Both were painfully burned, but Hughes later appeared on the track again. The Fiat's frame was twisted and cracked, and its springs broken, putting it out of the race.

A few minutes later came the fatal accident. At the clubhouse turn the Stearns collided with the Acme, and instantly all was a terrible confusion. The car turned a somersault and was smashed into fragments. Leonard Cole, the mechanic, was frightfully mangled, and Grosso's back was broken. The two twisted forms

Leading Renault and the Allen-Kingston Have a Brush About Noon—Paddock in the Background

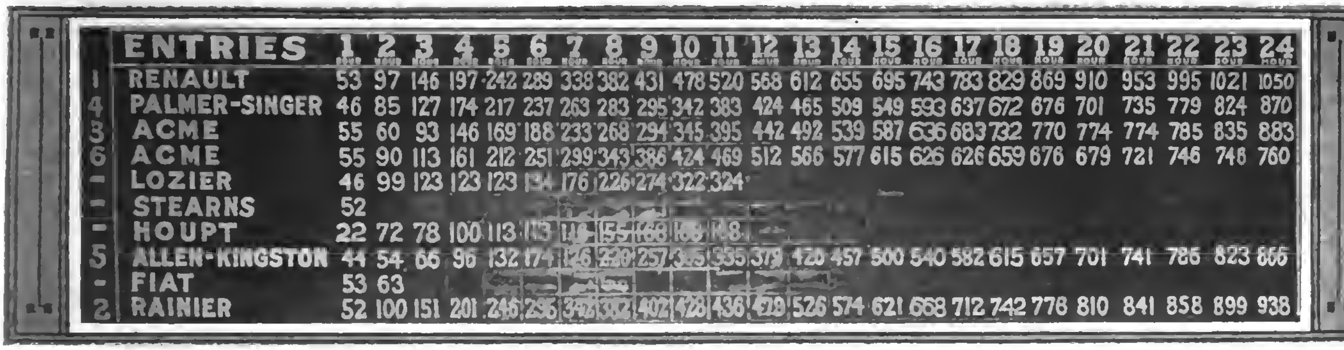
lay near the wreck of the car for some moments while the other cars were signalled to stop. The ambulance took away the Stearns crew, one dead and the other dying, and the pieces of the big car were pulled into the field. Patschke in the Acme had retained control of his car, and drove to the paddock, where the front axle and construction was replaced. The Renault had been in the mix-up, too, and its steering cross-rod had to be straightened.

The race was resumed at 11:40, and half an hour later the front wheel of Acme No. 4 gave way while rounding the clubhouse turn. With great presence of mind Van Tine steered the car through the canvas fence and brought it to a stop, avoiding a mix-up with the pursuing cars. At the end of the second hour the Rainier led, scoring 100 miles. About 1 a. m. the Lozier, driven by Heina, blew a tire and broke a wheel on the far turn and upset; the driver and mechanic were thrown across the track, but picked themselves up with only a few bruises. The two Acmes were both on the track an hour after the accident and started to make up lost time. The driving of both Patschke and Van Tine was of the sensational order. About daybreak the Allen-Kingston in leaving the paddock upset a lamp post, which struck Patrick Corrigan, a policeman, and put him on the hospital list with a fractured leg and dislocated knee.

During the eighth hour the Renault, carefully driven by Basle, overtook the Rainier and gradually drew into the lead, despite the latter car's desperate sprinting. Van Tine's Acme was in third place and the Palmer-Singer fourth. The Lozier, which had reappeared, was put out of the race for good at 8:25. Its left rear tire burst on the turn into the backstretch and it went through the fence, breaking its front axle. Heina and his mechanic again escaped unhurt. About the same time the Houpt burnt out its connecting rod bearing and was withdrawn.

Charles Basle in the Winning Renault—Just After Finishing

Laurent Grosso and Leonard Cole, in the Unfortunate Stearns



Scoreboard Could be Read from the Grand Stand—This Photograph Taken by Night, After the Finish

The succession of accidents now was broken, and the remaining six cars continued to the end of the race. The Renault steadily increased its lead over the Rainier, and the latter opened up a wider gap on the rest of the field. Basle settled down to a humdrum pace, and the race assumed the aspect of a procession. A good-sized crowd assembled in the evening and divided its attention between Patschke's sprinting and Pain's fireworks, which were visible over the fence. The finish lacked enthusiasm, and the crowd quickly scattered to other attractions.

In the preliminary events Friday afternoon Woltman in the Hupmobile won the six-hour race, making 226 miles, after Adams and the S. P. O. had been disqualified for dirty work on the turns. Adams was suspended for thirty days. The other S. P. O. was second with 212 miles. De Palma and the Fiat "Cyclone" won the five-mile in 5:14 3-5, with Kilpatrick and the Hotchkiss second, in 5:16 4-5. In getting off on a false start the "Green Dragon" driven by Gilhooly went through the fence on "Death Turn," owing to the edge of the cement surface breaking his wheel. The "Red Devil" driven by Charles Bowers stopped on the backstretch and did not finish.

Walter Christie with his front-drive racer, gave an exhibition mile trial, but the best time he dared make was 57 4-5. His car called forth some applause, and it was evident that it could have gone faster if it had been able to hold the track. De Palma made two attempts in his Fiat "Cyclone," making 57 flat and 55 4-5 on the second trial.

No.	Car	Drivers	H.P.	Cyl.	Drive	Tires
1	Renault	Basle, Raffalovich	42	4	Shaft	Michelin
2	Palmer Singer	Lescault, Howard	57	6	Shaft	Diamond
3	Acme	Patschke, Dearborn	60	6	Chain	Goodrich
4	Acme	Van Tine, Bowers	51.6	6	Chain	Goodrich
5	Lozier	Cobe, Heina	51.6	6	Shaft	Diamond
6	Stearns	Grosso, Mulford	46	4	Chain	Diamond
7	Houpt	Robertson, Poole	48.4	4	Shaft	Michelin
8	Allen Kingston	Hughes, Lawwell	48.4	4	Shaft	Diamond
9	Fiat	DePalma, Parker	42	4	Chain	Michelin
10	Rainier	Disbrow, Lund	40	4	Shaft	Michelin

Despite numerous protests, and the condemnation of the daily press, the Motor Racing Association announces that it will hold a third race in September during the Hudson-Fulton celebration. The association denies that the condition of the track was responsible for the accidents, and says that they might just as well occurred if the track had been a hundred miles in circumference. However, there were some very bad spots later in the race. The Rainier Motor Company has made public a resolution not to participate in any more twenty-four hour races, being convinced that under present conditions such races are dangerous and against public sentiment. Others will doubtless follow its lead.

Parking Spaces Filled with Large and Expensive Private Automobiles

Wright Aeroplane in Flight: Photograph Was Taken from a Balloon

CURIOUS PHOTOS OF WRIGHT AEROPLANE

Photographing one air craft from another is still a novelty, and these pictures taken from a balloon, have the additional merit of depicting more clearly than otherwise would be possible the appearance and proportions of the Wright aeroplane and the method of launching it into the air. The arrangement of the front and rear rudders, the pylon and starting rail are all plainly visible, as well as the position of the operator. In one photograph even the rapidly turning propellers can be distinguished.

Just Leaving the Starting Rail

In the lower photograph the machine has just been placed in position on the starting rail, and the weight, the fall of which provides the initial impulse, is being hoisted to the top of the tower. A rope runs from the weight through the pulley at the top of the tower, thence to the ground, under the starting rail to a pulley at the far end, and then back to the aeroplane, to which it is connected by a catch that is automatically released at the end of the rail. In one of his flights at Fort Myer, however, Orville Wright succeeded in starting from the rail without the use of the falling weight, the thrust of the revolving propellers proving sufficient to take the machine off in good shape. It is predicted that the Wrights will soon discard the weight altogether.

Another photograph shows the machine just leaving the end of the rail. The forward lifting planes have been tilted so as to raise the front edge of the main planes; the greater lifting effort resulting from their increased angle then raises the machine gently in the air. If the wind is favorable it is often not necessary to run the full distance before taking flight.

One of the surprises of the Rheims aviation meet was the skilful work of Lefebvre, who in ten days taught himself to operate his Wright machine. He made his first trials on the broad meadows of Holland. First he balanced the machine on a pivot in a wind blowing 10 feet a second, and endeavored to handle the horizontal rudder and the flexible wing tips in such a way as to maintain it in equilibrium. Then he had laid a rail about 90 yards long, and got several mechanics to push him along it while he maneuvered the rudders. At last he gained sufficient confidence to start the motor, and then, one fine day, he flew away. A few days later he took his machine to Rheims and won. Everyone who has ever ridden in a Wright aeroplane has commented on the ease with which it is controlled.

Flying Low and Racing With Its Shadow

Ready to Be Started by the Falling Weight

RHEIMS TOURNAMENT AFFORDS GLORIOUS SPECTACLE

RHEIMS, Aug. 29—Marvel has succeeded marvel in the aviation meet on Bétheny Plain. Aeroplanes by the score have flown there; skimming the ground with planes gleaming white in the sun; soaring majestically against a background of crimsoned clouds, or darting, a narrow line of black, across the face of the harvest moon. Never before in history have such scenes been witnessed. Stevenson's locomotive, Fulton's steamboat meant but the spreading of man's dominion on earth. Now we have conquered the air.

The simple, matter-of-fact way in which this aviator or that orders out his machine, guides it into the air and takes a spin around the course leaves the spectator with the feeling of having just awakened from a Rip Van Winkle nap. These wonderful craft start in flight as easily as any bird; they soar high, or ripple the tall grass with their wind, as their masters please; they pass each other in every direction, crossing above or below, sometimes tossing in each other's wakes; again two or three race neck and neck at express-train speed. The mechanics, who turn their backs on any ordinary flight, the hangers-on, the race-going populace, speak a jargon of planes, tails, equilibrium, air currents, which one a year ago would have thought the ravings of a lunatic. An aviator brings his machine to earth in front of its shed and asks for his time on the lap; the crowd presses around and comments critically. Even the bookmakers are here, quoting odds on Curtiss or Bleriot. Aeroplanes of the Wright, Voisin, or Bleriot types are sold at list prices, and the buyers squabble over deliveries.

Each day has seen its heroes. Monday, Curtiss made a record for the course. Tuesday, Bleriot broke it. Wednesday, Paulhan broke all records both for distance and time in the air. Thursday, Latham made a new record of ninety-six miles, though in less time than Paulhan's trip. Then both were surpassed by Farman on Friday, when he traveled more than 112 miles, only stopping because of the darkness. Saturday, Curtiss won the International Cup, the greatest prize of the meet, and Bleriot made a new record for a single lap. On the last day Curtiss set a record for three laps; Latham ascended to a height of 500 feet, and Farman carried two passengers around the course at a speed of 35 miles an hour.

Accidents have been remarkably few, and none serious. Several aeroplanes were more or less smashed. Bleriot was the most unlucky; Thursday he ran his big 80-horsepower monoplane into a fence while trying to land in front of the grandstand, breaking its wings and propeller, and Sunday, while in full flight with his smaller machine, the rudder failed to respond, with the result that the machine crashed to the ground, the burst gasoline tank caught fire, and the aviator was painfully burned. Fournier, the hero of many automobile races, suffered a broken nose. Other aviators occasionally bumped fences or hay-stacks, but without serious consequences.

The races were arranged and conducted in such an orderly manner that it has been possible to make a complete summary of them, and even to figure the scores of the aviators and the types of machines, as in a track meet. Latham and the Antoinette monoplane are the largest individual scorers, but in totals the biplanes surpas sthe monoplanes.

THE SUMMARY OF RHEIMS

Prix de la Vitesse: 3 laps, 30km. (18.6 mi.)

Pos.	Aviator	Aeroplane	Time
1	Curtiss	Curtiss	23:29
2	Latham	Antoinette 29	25:18 1-5
3	Tissandier	Wright	28:59 1-5
4	Lefebvre	Wright	29:00
5	De Lambert	Wright	29:02

Prix du Coupe Internationale: 2 laps, 20 km. (12.4 mi.)

Pos.	Aviator	Aeroplane	Time
1	Curtiss	Curtiss	15:50 3-5
2	Bleriot	Bleriot	15:56 1-5
3	Latham	Antoinette	17:32
4	Lefebvre	Wright	20:47 2-5

Prix du Tour de Piste: 1 lap, 10 km. (6.2 mi.)

Pos.	Aviator	Aeroplane	Time
1	Bleriot	Bleriot	7:47 4-5
2	Curtiss	Curtiss	7:48 2-5
3	Latham	Antoinette 29	8:20 3-5
4	Latham	Antoinette 13	8:32 3-5
5	Lefebvre	Wright	8:58 4-5

Prix de la Champagne: Greatest Distance

Pos.	Aviator	Aeroplane	km.	(mi.)
1	Farman	Farman	180	(112)
2	Latham	Antoinette	155	(96)
3	Paulhan	Voisin	131	(81)
4	De Lambert	Wright	116	(72)
5	Latham	Antoinette	111	(69)
6	Tissandier	Wright	111	(69)

Prix de l'Altitude: Greatest Height

Pos.	Aviator	Aeroplane	m.	(ft.)
1	Latham	Antoinette	155	(494)
2	Farman	Farman	110	(361)
3	Paulhan	Voisin	90	(295)
4	Rougier	Voisin	55	(180)

Prix des Passagers: 1 lap, 10 km. (6.2 mi.)

Pos.	Aviator	Aeroplane	Time
1	Farman	Farman, 2 pass	10:39
2	Farman	Farman, 1 pass	9:52 4-5
3	Lefebvre	Wright, 1 pass	11:20 4-5

Prix des Dirigibles: 5 laps, 50 km. (31 mi.)

Pos.	Aviator	Aeroplane	Time
1	Kapferer	"Col. Renard"	1:19:49 1-5
2	De la Vaulx	"Zodiac"	1:25:01

INDIVIDUAL SCORES OF THE RHEIMS MEET

Aviators	Firsts (5 pts.)	Seconds (3 pts.)	Thirds (2 pts.)	Fourths (1 pt.)	Total
Latham	1	2	2	0	15
Curtiss	2	1	0	0	13
Farman	2	1	0	0	13
Bleriot	1	1	0	0	8
Lefebvre	0	1	0	3	6
Paulhan	0	0	2	0	4
Tissandier	0	0	1	0	2
De Lambert	0	0	0	1	1
Rougier	0	0	0	1	1
Aeroplanes					
Antoinette	1	2	2	1	16
Curtiss	2	1	0	0	13
Farman	2	1	0	0	13
Wright	0	1	1	4	9
Bleriot	1	1	0	0	8
Voisin	0	0	2	1	5

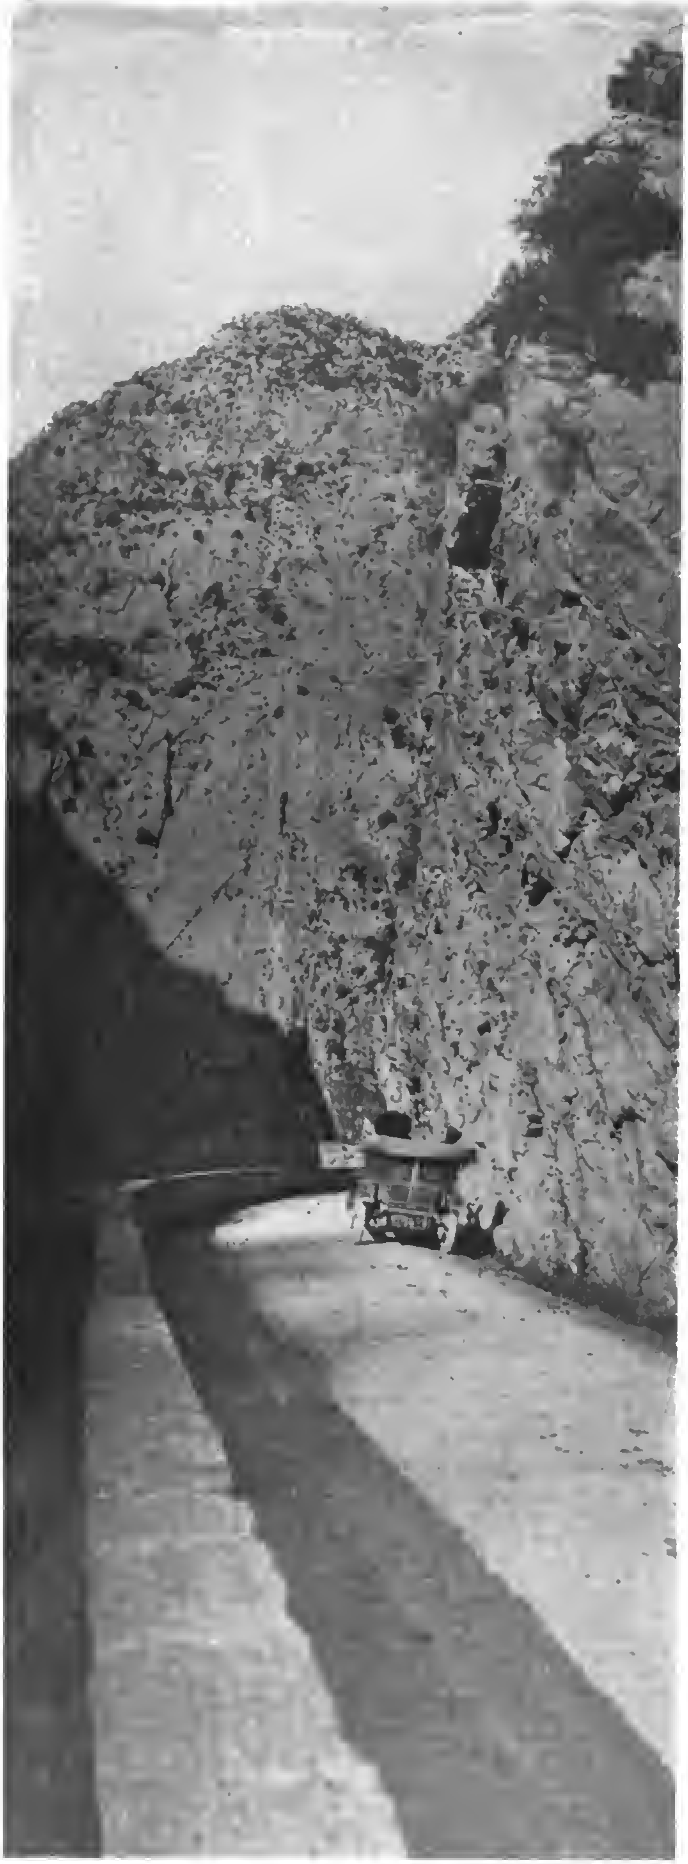
BLERIOT'S MACHINE WILL BE HONORED

PARIS, Aug. 20—When it comes back from England, Bleriot's most successful flying machine will be given an honored position in the Arts and Metiers Museum in Paris, where it will have as companions Wilbur Wright's original flyer, with which he made all his records in France, Ader's flying machine, the first in Europe to rise from the ground, and Cugnot's steamer, the precursor of the automobile. Louis Bleriot preferred to sell his machine to the City of Paris for $2,000 in preference to disposing of it in England for ten times that amount. The price he is obtaining for it from the French authorities is the actual cost of production, this type of machine now being sold for $2,000.

Although having a well-equipped factory, and a business organization behind him capable of handling orders on a large scale—for Bleriot is also the head of an auto lamp factory.

CODY SUCCEEDS WITH BRITISH FLYER

LONDON, Aug. 20—This country may at last claim to possess a successful aviator, for S. F. Cody has vindicated the claims so long made for his army aeroplane. Recently the machine made three two-mile circuits of Laffans Plain. Subsequently, this performance was repeated and a six-mile cross-country journey was successfully essayed. This last trip was accomplished with the machine carrying ballast to represent a passenger, so that afterward passenger flights were frequently tried. Mr. Cody has entered for the Liverpool to Manchester £1,000 prize. The machine is of the tailless biplane type and is one of the heaviest that has yet been constructed, weighing over one ton. The framework is made of bamboo struts with metal joints. The engine is an eight-cylinder E. N. V. of 80-horsepower, operating by chains two propellers situated between the main planes.



"Beyond the Alps Lies Italy": a Road in the Maritime Alps

ITALY AS A TOURING GROUND

Cortlandt Field Bishop has been an inveterate European tourist for a number of years, and being of an observing nature, he has frequently supplied information which has been of much value to other automobilists in their travels abroad. Recently, Mr. Bishop completed a tour of Italy, and in an article printed in the Paris edition of the New York *Herald*, he comments as follows:

"Speaking generally, roads in Italy have improved during the last few years and are becoming better. In many parts, notably around Milan, Naples and Turin, the steam roller is employed. Improvements have also been made in gradients.

"The rule of the road in Italy is rather a troublesome question to automobilists owing to its lack of uniformity. This is a relic of the time when Italy was divided into a number of independent states. Before the advent of the automobile, when traffic was only local, this absence of uniform regulations was not of much consequence. But when automobiles began to tour through the country they quickly discovered its inconvenience. It was frequently impossible to know when one passed from one former political division into another, and, consequently, whether to continue to keep to the right of the road or to change over to the left or vice versa.

"This uncertainty partially disappeared a few years ago with the passing, largely through the efforts of the Touring Club of Italy, of a law requiring all traffic to keep to the right, as in France and America. At the same time a kind of local option in the matter was granted to cities of a certain size. It was stipulated, however, that where the general rule of the road was not in force that fact should be plainly indicated at all the octroi stations. Rome, Milan and Genoa took advantage of the option, and within the limits of these cities vehicles must keep to the left and pass each other on the right.

"Although the rules of the road have thus been simplified in Italy, it is still necessary to use caution, especially in the neighborhood of large cities. The peasants are gradually getting accustomed to automobiles, but the country people, in their high, narrow, two-wheeled carts, have not lost the habit of sleeping on the road, and if they awaken at the sound of a horn are just as liable to pull to the left as to the right. Heavy ox teams also cause a considerable amount of obstruction, while in the vicinity of large cities the presence of cyclists, who are more numerous in Italy than in France, necessitates careful driving.

"Automobilists touring in Italy have at their disposal, thanks to the T. C. I., a better and more complete series of road maps and road information than in any other country in Europe.

"The Touring Club's latest achievement is the publication of the first part of a road map of Italy, designed solely for the use of automobilists. The main roads are marked out in bold red lines, with the distances given between the principal points. This is accompanied by a pamphlet which shows the best routes for passing through and in or out of the principal cities of Italy. The main thoroughfares to be used in passing through are printed in red letters.

"The Simplon was the first modern carriage road to be built across the Alps. It was built by order of Napoleon I after his disagreeable experiences on the Great St. Bernard, although he never crossed it. This road is now a favorite with automobilists.

"There have been some recent changes in the rules regulating the passage over the Simplon Pass by automobiles, and these are not generally known. Until this year it was impossible to enter the pass after 4 o'clock. Now the time is extended to 5 p. m. The time allowed for crossing is four hours and not four hours and a half as is generally supposed. This year the pass was opened to automobiles after May 20, instead of June 15, as formerly was the case. The Simplon is a good piece of engineering: automobiles have been allowed to pass only for the last four years, and the amount of automobile traffic on it can be imagined from the fact that during the four months of last season 550 machines passed over it."

Automobile Wheels, Rims and Tires

By Thos. J. Fay

ROAD SHOCKS must first be taken by road wheels, through tire contact, and thence the vibrations traverse, spreading out in all directions, from the hubs of the wheels. What happens to the car as a whole may be set aside for the time being, rather with the expectation that there is much to be said of a pertinent character before the wheel subject will be adequately explored. Resilience, that rather indifinite term, is continually used in explaining just how wheels, aided by tires, accomplish the work for which they are placed.

According to Rankine, resilience is synonymous with spring, and "is the quality of mechanical work required to produce the proof strain, and is equal to the product of that strain, by the mean stress in its own direction which takes place during the production of that strain—such stress being either exactly or nearly equal to one-half of the stress corresponding to the proof strain." * * * Rankin goes on to say: "Each solid has as many different kinds of stiffness, toughness, strength, and resilience as there are different ways of straining it; pliability is used as a general term to denote the inverse of stiffness."

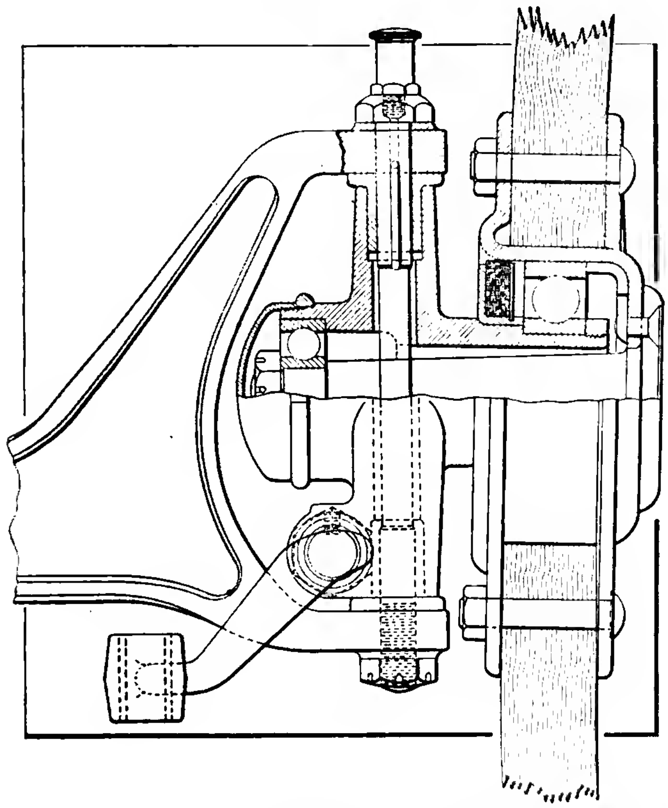


Fig. 1—Example of inverted swivel hub offering advantages in the direction to dispel steering moments

Resilience, then, may be properly used under all sorts of conditions, especially in connection with wheels, rims, and tires, but in the absence of "specifications" the term possesses little or no actual significance. In the same way there are many big words used to describe, in glowing terms, the fine qualities of the wheel-maker's art, nearly all of which fail to afford to this ancient craft a simple measure of "horse sense" which, after all, is the basis of wheel-making, built up, as it is, on a foundation of experience dating from wheels for carts which rolled over the first road built by one of the Pharaohs, during the fourth dynasty, which road was about a mile in length, taking on the features of a causeway, leading up to the sight of the Great Pyramid, the date of which is generally considered to be as early as 4,000 B. C., according to accepted authority.

Automobile Makers Eliminated the Fifth Wheel—When the first automobile was designed and constructed the fifth wheel was retained, on which the turning depended, but it was soon found that, at the higher speeds attained by automobiles, this primitive method of steering was attended by dangers. In time it was concluded that when the plane of the steering road wheel is in the plane of the steering pivot, the effect of road inequalities will not be transmitted to the steering gear, or, if a line passing through the center of the road wheel at right angles to the axis of rotation, bisects another line, which, in turn, passes through the turning pivot, provided the point of bisecting is at the point of tire contact with the road, the effect of road inequalities will not be transmitted to the steering gear.

Fig. 1 is offered to show that the ills of road inequalities may be thwarted to a vast extent, in that the road wheel may be very close to the pivot in the knuckle, and the angle of the road wheel, which is usually 1 1-2 degrees out of the vertical, will then be enough to assure that the point of bisecting will be at the point of ground contact of the tire. Fig. 2 is more conventional, representing, in a general way, many of the examples to be seen in actual practice, and in order to indicate more nearly the competence of this plan it is only necessary to glance at Fig. 9, in which the line A O′ passes through the center of the road wheel and the line A′O′ passes through the axis of the knuckle pin, but the lines, so drawn, do not bisect at the point of contact of the tire on the road wheel with the ground. The actual difference is about equal to the radius of the section of the tire, and to this extent the effect of road inequalities will be transmitted to the steering gear, which is made semi-irreversible to compensate for this difference. Absolute irreversibility is not desired since shock would then be augmented.

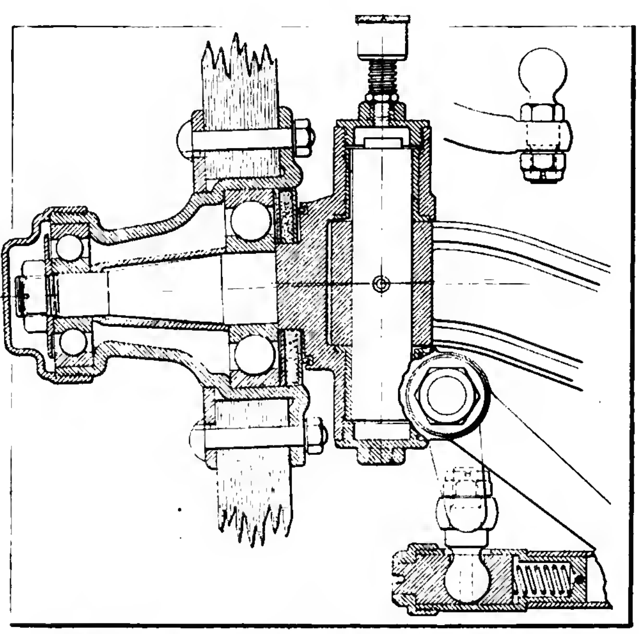

Fig. 2—Example of a conventional steering wheel knuckle, with the road wheel center close to the pivot bolt.

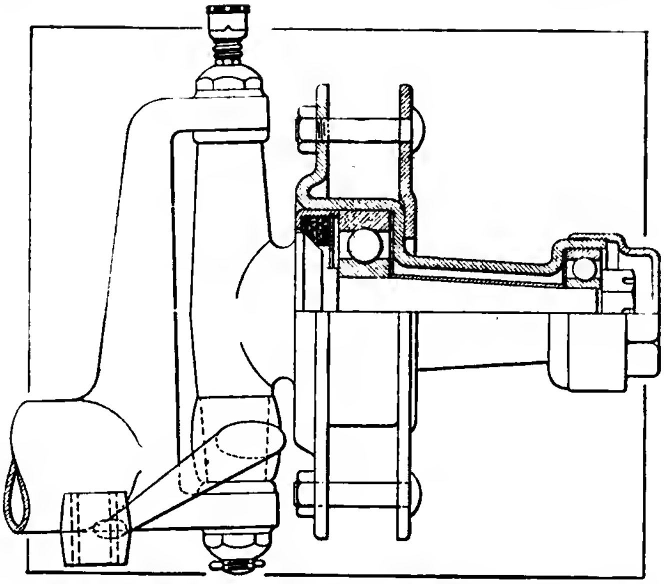

Fig. 3—Depicting annular type ball bearings in a hub made of drawn steel, with a drop forged knuckle

It would be possible to reduce the distance O O', Fig. 9, by quite an appreciable amount, but it would be at the expense of additional "dish" of the road wheels; even 2 degrees looks over much in actual practice, and besides, the object in placing the wheels out of the vertical plane is to ride the weight of the car on "plumb" spokes, which to do, must take into account the crown of the road, which is never more than 1 degree, and rarely so much. Crown of the roadbed is determined as follows:

Let,

O = equal ordinates in inches.
C = crown in inches.
R = one-half width of the roadway.
D = distance from center to any point in feet.

when

$$O = C\left(\frac{D}{R}\right)^2$$

Frequently the crown of the road, at the center, is on a basis of 9 inches per 100 feet, which represents 3-4 of 1 per cent, and this is about all the difference that should be noticed in any endeavor to render the spokes in the wheels plumb. There is one more point to be considered, i.e., lost motion in the knuckle joints will augment the trouble due to crown of the roadbed, and this, together with the effect of crown, makes it necessary to fix the angle of the wheels, with respect to true vertical plane, 1 1-2 degrees out of the vertical plane, which should be maximum.

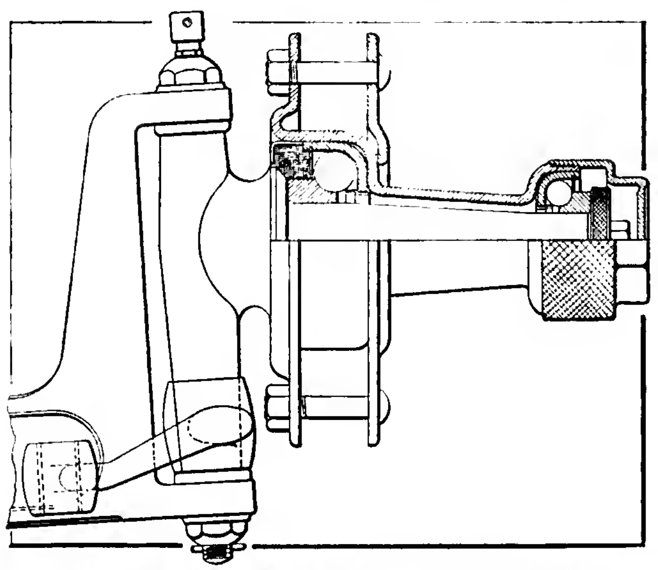

Fig. 4—Same as Fig. 3, excepting that the ball bearings are of the cup and cone type and adjustable at will.

While Fig. 1 depicts a nearly perfect canting knuckle for front wheels, Fig. 2 accords with practice to a considerable extent, referring to the location of the knuckle turning bolt, and a close inspection of the two figures, in contrast, will be enough to show that there is but little difference between them as respects the centers of moments. The design, Fig. 1, is interesting in that it shows how to hide the hub of the wheel so that it will not protrude far outside of the protecting boundary of the pneumatic tire, which may be a good point.

Hubs Differ in Important Particulars—Formerly, owing to the extended use of plain bearing artillery types of wheels, the hubs were relatively long, and the general appearance was in some contrast with present practice. Then, hubs were frequently made of cast gray iron, although it was soon found that, for live rear axle types cast iron frequently failed, due to the conditions involved in keying the shaft to the hub. It was found that the relatively small diameter shaft induced a condition of high pressure, and the key burrowed into the cast-iron hubs of the driving wheels. Many failures resulted in this way.

As anti-friction bearings came into vogue, they indicated the need for better hub construction, due in a large measure to the requirements of accuracy, and lightness finally became the goal for all ambitious designers, who, in their desire to eliminate unnecessary flywheel effect, made wheels of increasing strength

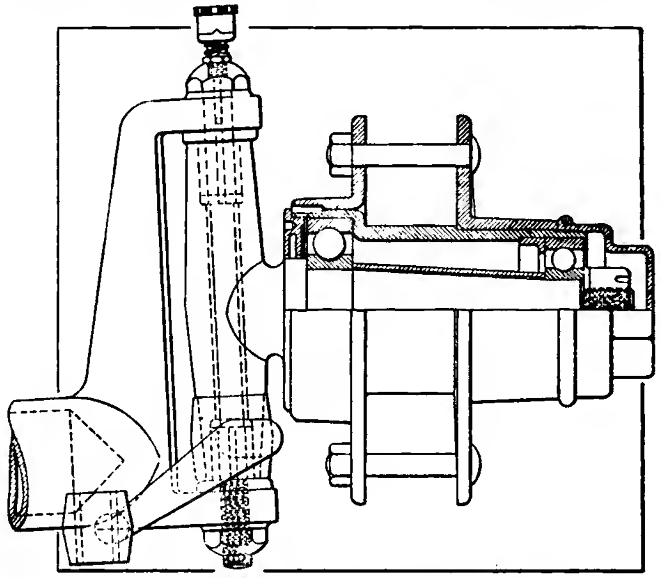

Fig 5—Front wheel hub with annular ball bearings in which the center of the wheel is too far from the center of the knuckle pin

and gained a double victory, since lightness was a natural sequence. Fig. 2 indicates just how lightness followed strength, due to the scheme of design, which took into account an even thickness of hub-walls. The same figure shows how annular types of ball bearings may be properly mounted, with provision for clamping the inner races, which is a necessity, although, in this example, the plan is penalized since there is no allowance for axle-wise floating of the outer raceway. Referring to Fig. 10 it will be observed that the outer raceway is provided with adequate axle-wise clearance, as indicated by a a, which allowance should not be less than 0.5 millimeter (about 0.020 inch).

A Safety Washer Should Be Used in Every Case—Considering annular types of ball bearings, it is desirable to use a safety retainer (washer) in front of the outer ball bearing, back of the hub nut, as shown in Figs. 2 and 11. This washer will prevent the bearing from dissembling even if a ball does crumble, however remote this contingency really is. Fig. 5 shows defective designing in that the safety washer is not present; outer races are cramped, and the spacer between the inner racs is so thin that it is likely to fail in service. The spacer shown in Fig. 2 is somewhat more substantial, but a better plan is depicted in Fig. 12, which represents a design promulgated by the Hess-Bright Manufacturing Company, involving the use of a specially shaped spacer, which also serves as a safety bearing, which would come into play were the ball bearings to fail since the spacer is so fashioned that it offers bearing surface for the hub between the inner and outer ball bearings to come down upon.

In connection with the hub, as shown in Fig. 12, the same makers compiled a table affording such information as would seem to be required in the selection of Hess-Bright ball bearings, giving dimensions, and bearings to use when the conditions are normal. This table is here given:

HESS-BRIGHT WHEEL HUBS AND BEARINGS TO USE

Carrying Capacity of Hub in Pounds			Axle Diams. Inches		Bearing Number		Centers Inches	
Pneu. Tires	Solid Tires	Steel Tires	A	B	A	B	C	D
400	300	240	.4724	.9842	301	305	1	1 3-4
620	465	370	.6693	1.1811	303	306	1 1-8	2 1-4
730	550	430	.7874	1.3779	304	307	1 5-16	2 5-8
1000	750	600	.9842	1.5748	305	308	1 7-16	2 7-8
1600	1200	965	.7874	1.7716	404	309	1 3-4	3 1-2

Bearing Selection: When center distance $C = \frac{D}{2}$:

Mr. Hess points out that the inner bearing must take the larger proportion of the load under the usual conditions, and in selecting bearings his recommendation is to first determine the proper size for the set of bearings and then take the next larger regular

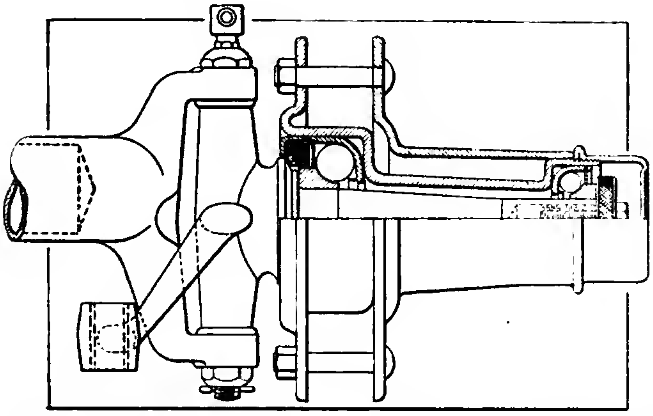

Fig. 6—Front wheel hub with cup and cone ball bearings, felt closure, and cap screw replacing a hub nut

size for the inner bearing. Some recommendations are also made, which would seem to be well drawn, as follows:

CONSTRUCTION NOTES

Both inner and outer races of both bearings to be a neat slip fit.
Both inner races to be clamped endwise under pressure.
The inner bearing to take endthrust.
The inner bearing outer race to have 1-64" side clearance.
Front and rear hub caps should be securely locked.
Water and road grit must be kept out.

Design Depends Upon Tires Used—Glancing at the table it is to note that the burden which it will be safe to employ in view of a given set of bearings will depend upon the tires; while this is a matter which involves the bearings, even so, if larger bearings are required when tires are solid than would be used with pneumatics, then the hubs must be larger, in order to take the larger bearings. According to the table made up for Hess-Bright bearings, the hub carrying capacity will be as follows:

RELATION OF CARRYING CAPACITY TO TIRES USED

Carrying Ratio of Tires Pneumatic	Solid	Steel
100	75	60

The above relations do not assume that the speed of the car will be on a constant basis; obviously, pneumatic tires will allow of the highest speed, solid (rubber) will come next, and steel tires will be at the foot of the speed list.

This question of speed, in view of the tires used, and load carried, was discussed at the 1909 summer meeting of the Society of Automobile Engineers, and in his paper ("Energy Con-

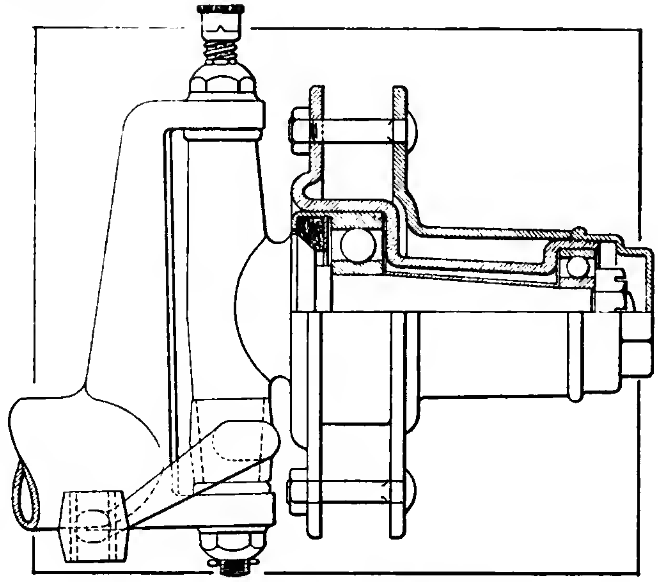

Fig. 7—Drawn steel hub, annular ball bearings, and hollow knuckle swivel pin with grease cup lubrication

sumption of Commercial Vehicles") Alexander Churchward gave for the most economical speeds, among other data, the following:

ECONOMICAL SPEEDS CONSIDERING TIRES AND LOADING

Gross Weight	Type of Tires	Speed in M. P. H.
1,500	Pneumatic	20
2,000	"	20
3,000	"	18
4,000	"	16
2,000	Solid	16
3,000	"	15
4,000	"	13
5,000	"	11

The above speeds cannot be construed as limiting, but it was the idea of the author that they represent (all things considered) the maximum from the point of view of economy.

Hubs, while they can scarcely lay claim to an overplus of quality if they are made of cast gray iron, are frequently made of drawn steel, and in this process, light weight, great strength, and relatively low cost, share equally. For examples of drawn steel work reference may be had to Figs. 3, 4, 6 and 7, while Fig. 8 shows a steel casting for the hub proper, with a pressed steel-tubed flange piece. This same figure gives, in cross-section, a brake-drum, and while the subject of brakes is somewhat separated, even so, the rear wheels must be fashioned to take the drums, and to this extent it is desirable to give the matter attention here, from the point of view of fastenings.

The drum, as shown in Fig. 8, is of drawn steel, with uniform thicknesses of walls and machined with considerable accuracy, so that it flanges onto the hub, fitting in the recess provided and in

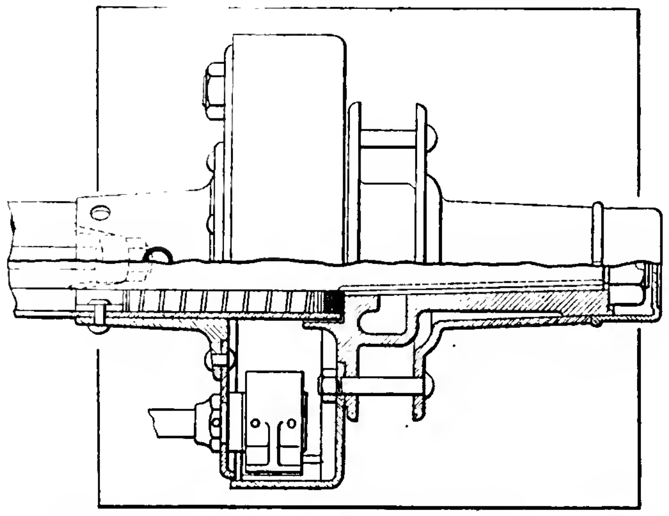

Fig. 8—Hub for live rear axle showing Hyatt roller bearings and felt closure, also close nesting and light weight.

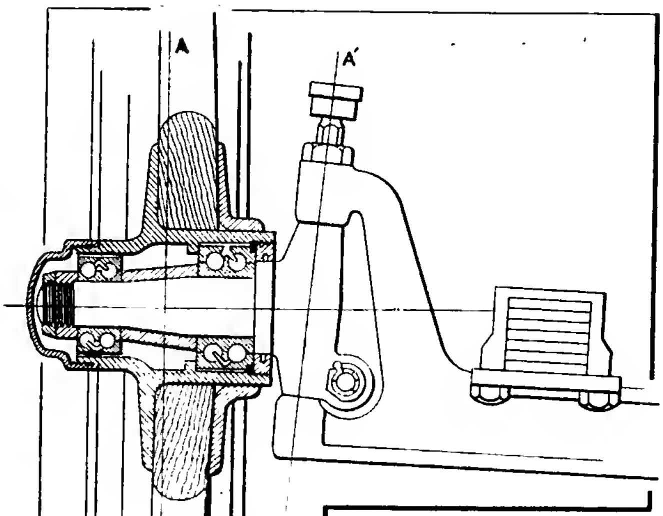

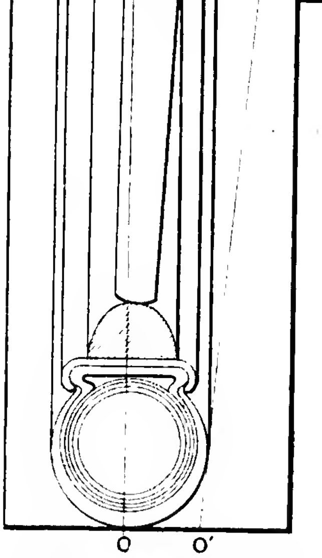

Fig. 9—Diagrammatic front wheel assembly, with New Departure ball bearings, showing the difference O O'

every way representative of the kind of practice which makes for success. Steel castings may also be used, and it is generally possible to machine them to any desired size; they may be cast in quite intricate shapes, if the process is attended by the requisite amount of skill. That the drawn-steel products are a little better is generally believed, and that they are a little cheaper is a matter of experience, although, in the drawn-steel work, quantity production is essential to success.

Quality and quantity go hand in hand, as the above point adequately indicates, excepting that labor, involving as it does, accuracy of machining, must be taken up on a separate basis, although it cannot be shown that production in quantity must, of necessity, lead to inferior work. Workmanship, as a matter of fact, may be good, or bad, independently of quantity production.

Compactness Largely Influences Designing—In the class of cars using live rear axles, owing to the ill effect of excess weight, if the parts, as bearings, are relatively great in diameter, housings will have to increase accordingly; designers aim to select bearings which will do the work required without having to provide a large tube or housing. Fig. 8 depicts a case in point, in which Hyatt roller bearings are used, and, as the design shows, economy of space is a conspicuous feature. This particular example is devoid of the floating shaft principle, and the shaft is made somewhat larger since the bending moment, due to the weight on the wheel, must come on the shaft. The shaft may be a taper, or a parallel fit in the hub, and in the case in point the hub is made of extra length, which assures that the key will be of adequate ability. The hub-nut prevents the wheel from floating off, and with a sufficiently large shaft, if the axle is properly rated as to the load it will safely carry, there is no reason why it should not serve its purpose. Hyatt roller bearings are also used in semi and full-floating types of live rear axles as well, so that the style of design is a separate matter, excepting that weight, which is not desirable beyond the exact requirement, is held to a low limit when the bearings are of considerable length, rather than of great diameter.

Advantages of Floating Types of Hubs—If the shafts in live rear axles are free to respond to torsional moments only, it is self-evident tbat they may be smaller for the work, and

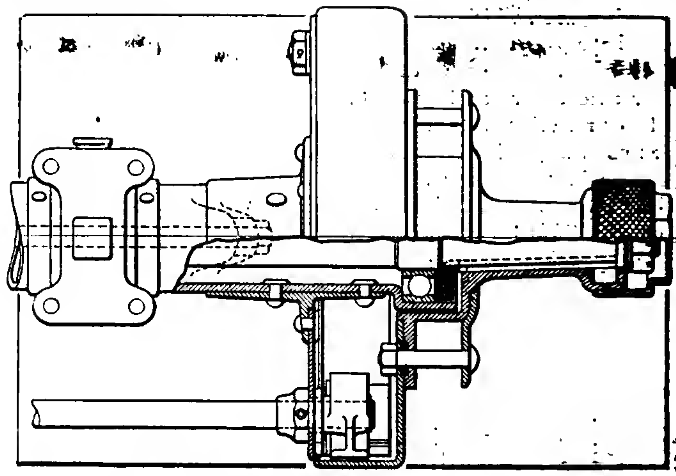

Fig. 10—Hub end of a live rear axle, showing drawn steel brake drum attached to hub flange

strength will reside in them to a marked degree. On the other hand, if the driving jaws, in the hub of the wheel, are not liberally fashioned and nicely fitted lost motion will be present, and a little of this lost motion is as a "nest egg." As an illustration of this point, it is only necessary to call attention to the varied character of the service rendered by keys in practice when they are properly proportioned and tightly fitted they do the work very well, indeed, but if they are not tightly fitted, even though they may be large enough, they will soon generate lost motion and fail in service. What is true of a key or a feather holds for a set of driving jaws, and no matter how they are made, if they are not properly fitted the end will be disastrous. Fig. 14 shows a fine example of a full-floating type of live rear axle in which the bearings are of the annular type, and the driving jaws at the ends of the shafts engage with the hub in a proper manner to abort failure from lost motion.

In this case the tube is reduced in diameter to take the bearings, and the shoulder so formed is taken advantage of in the process of providing for thrust. The shaft has no work to do excepting to take torsional moments, and the design throughout includes drop forgings of steel and drawn-steel parts. The inner races of the ball bearings is a sufficiently heavy tube, but it is not shaped in such a way as to act as a "preventer bearing," hence complete dependence is placed on the ball bearings and they are made large enough to take the responsibility. This class of hub work is much in evidence in various makes of cars, and this particular example is from the 1910 McCue car.

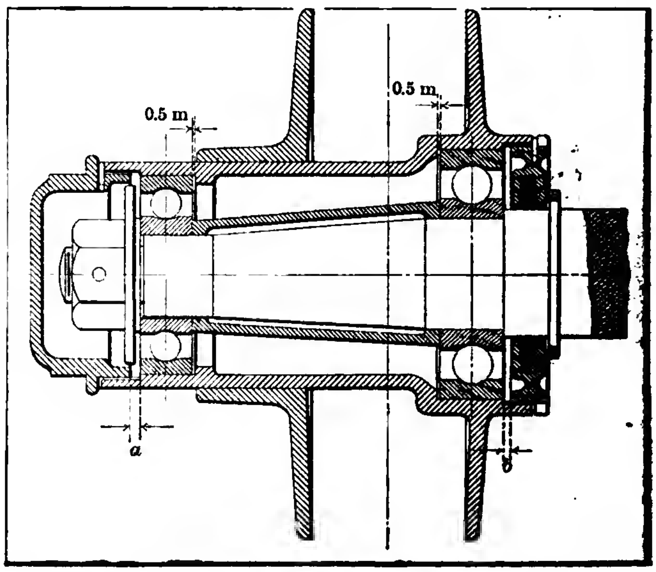

Fig. 11—Section of a hub with annular type ball bearings with inner race clamped and outer race floating

Hub-Caps Should Be Locked On—The main idea in using hub-caps is to protect the bearings, which is a matter of the introduction of a suitable lubricant and retaining the same in place to the entire exclusion of the silt of the road. It is too much to expect that a hub-cap, merely because it is screwed on, unless it presses up against a shoulder and is a good fit, will stay on under all conditions. If a locking device of some suitable design is used, there will be small chance of recording the loss of a hub-cap, and while there is no direct hazard attached to the loss, even so, foreign substances are bound to depreciate bearings if they get to them. Fig. 3 shows one of the possible plans, and it has the virtue of being simple and effective. In this case the snap spring rests in a groove provided in the hub, and the inturning end of the lock engages with a hole passing through the hub-cap.

Closures Indicate Ingenious Application—One of the duties of hubs is to protect the bearings from rust and foreign substances; acid, which is also ruinous to ball bearings, will most likely come from the oil, and the way to avoid this class of trouble is to use unctuous, non-acid producing lubricant. That the lubricant will stay in is a necessity which will be readily accomplished if it is non-mobile, of adequate body, and if the closures are efficient for the purpose. The front end of a hub is easy enough to protect if a cap is used, and if it is locked on, or at least designed to stay in place until it is removed as a matter of necessity. At the rear of the hubs the situation is not so easy, and piano felt is employed extensively in this work, examples of which will be found in Figs. 1, 2, 3, 4, 6, 7, 8, 10 and 11. If the felt is of a good quality, steeped in boiling paraffine, success will attend its use, provided it is in sufficient presence and well supported. The felt washers to be of the greatest value should be 1-2 inch or more in face and approximately rectangular in section.

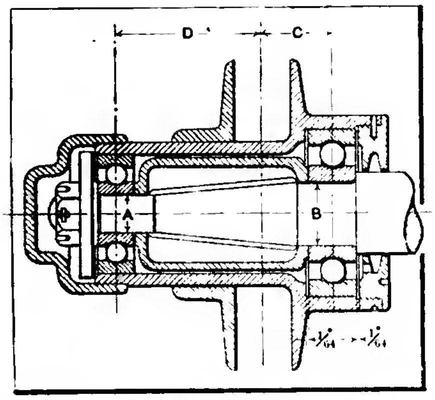

Fig. 12—Hess-Bright type of hub with annular type ball bearings and safety spacer which serves as a preventer bearing

When the closures are formed by V-shaped grooves in collars, as in Figs. 5, 9 and 12, the result will be very good, particularly if the grooves are liberally provided and means are included to drain the lubricant back to the inside. Fig. 13 shows a defective method which cannot possibly protect the bearing, whereas it might be the means of trapping water which could easily find its way into the cavity due to pressure from a hose when the car is being washed. Water indicates destruction.

Perfection Lies Buried in Details—Important as the general plan would seem to be, and however much attention may be accorded primary schemes, the end will not be in the plane of harmony unless all the details are looked to with the utmost care. Danger lies in considering that a hub of a wheel, for illustration, is but a crude device at best, and not entitled to the same discriminating care as would have to be accorded to a crankshaft, timer, or other important part.

When the mist of obscurity is lifted, it will be found that success lies absolutely in looking after details. As an example of the strenuous service wheels must render, let the pull, at the radius of the clamping bolts, be investigated, which for a case will be as follows:

When,

W = weight on one wheel in pounds.

f = coefficient of friction for rubber tires = .60 approximately.

R = radius of wheel in feet.

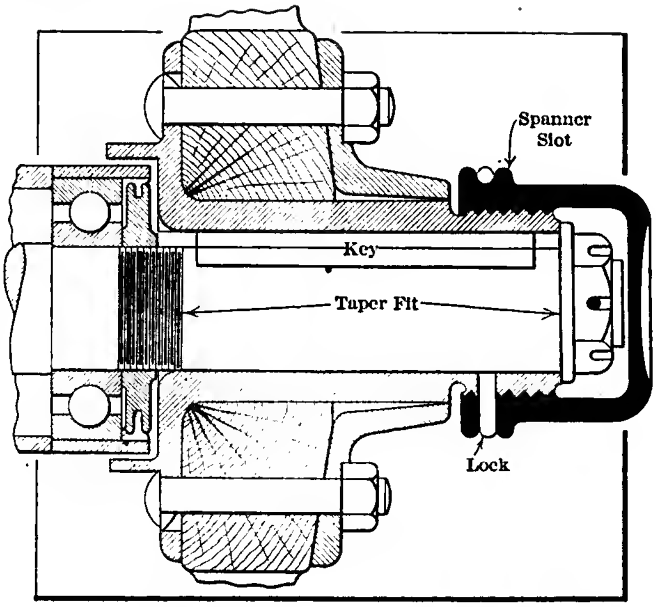

Fig. 13—Section of a hub in which the closure is defective and bending moments apply to the shaft

r = radius of clamping bolt circle in feet.

P = pull in pounds at radius of clamping bolts.

Then,

$$P = \frac{W f R}{r} = \frac{600 \times .60 \times 1.5}{.33} = 1{,}636.36 \text{ pounds.}$$

In which, the weight on the wheel is 600 pounds, and the radius of the clamping (flange) bolts is 0.33 feet or four inches. This will be the effort which will have to be exerted to skid the wheel, presupposing a motor capable of delivering the necessary torque, which is a normal expectation.

If this substantial figure, representing the pull which will come on the hub-flange bolts, under normal road conditions, must be considered, what is to be said about an abnormal case, as when a car is negotiating deep sand, considering a motor of great power, or better yet, if a large flywheel is added, thus rendering the motor capable of delivering a vast twisting moment momentarily?

The real hazard is, as yet, under cover; if the pull on the bolts, as above referred to, is a matter of concern, it is nominal in comparison with the work which will fall on the key, or the driving jaw in the hub, owing to the difference in position, the latter being closer, by a considerable margin, to the axis of moments. If 1,636 pounds will be exerted at a radius of four inches, the pull at one inch radius will be 6,544 pounds, and considering keying, the pull will be even greater since the radius of the center of the key from the axis is less than one inch in most cases. The pressure will still be present.

(To be continued)

Helpful in Overhauling the Car

By Stillman Taylor

ALTHOUGH a car requires and should be regularly given a certain amount of daily, weekly and monthly attention, this overhauling of certain parts is not enough to keep a car in the pink of condition. A thorough overhauling of the entire car is occasionally required, that the needed repairs may be made. It is only by this thorough overhauling that the owner can get a good idea of the car's condition, ascertain what parts show wear, and correct wrong adjustments which may have been previously made.

The principal reason for "knocking down" the engine is to find the exact condition of the pistons and bearings, as well as to clean out thoroughly any carbonized oil that may be found adhering to the cylinder walls. Make it a point to clean each and every part as it is taken apart. This should apply to nuts, bolts and other small parts as well as to the larger parts of the car. Do everything in a methodical manner, taking ample time. Many amateurs are prone to litter up the workroom with the various parts of the car, laying everything down in the most handy place. Avoid this confusion of the parts, by providing a sufficient number of boxes to accommodate the several units of the car, and keep everything pertaining to a certain part in its respective box. As soon as one part is unjointed or uncoupled, insert its pins or screws in their proper place before laying aside. This will prevent any small parts from being misplaced and save annoyance when putting the car together again.

To begin, the carbureter, pump, wiring, spark plugs and any other movable part fastened to the engine should be removed. When removing the magneto, the gear wheels of the engine and the driving pinion of the armature shaft should be marked with a punch at the point where they mesh, if not marked already. By taking this precaution the magneto may be assembled on the car in its proper place without disturbing the original ignition timing of the car. Each valve should be marked as it is taken out, that each may be replaced in its proper seat. It will be convenient to number them 1, 2, 3, etc., by punch mark.

The cylinder castings may now be lifted off the pistons and removed to the work bench. Some workmen prefer to lift cylinders and pistons off together; this is a good plan if a helper is at hand, but more difficult for one man than lifting the cylinder alone. But in assembling without assistance, and especially when the cylinders are cast in pairs or *en bloc*, the weight of the cylinder casting is considerable, and it is much less laborious first to assemble the cylinders with the pistons in their respective places, and so avoid holding up the heavy casting while fitting the cylinders. Then uncouple the connecting-rods from the crankshaft and remove rods and pistons together. Before taking down any other part of the car, it is a good plan to first clean out the cylinders with kerosene to remove any oil and so soften deposits of carbon adhering to their walls. If the deposit is light, this soaking may be all that is necessary, but where a considerable amount of carbon has gathered in the combustion chamber, the walls must be scraped, either with a suitable carbon scraper sold for this purpose, or with a file bent and sharpened to a cutting edge.

All the piston rings should be clean and bright; if any black streaks are found, it is a certain indication of leakage. All worn piston rings should be replaced. Examine the piston pin with a view to possible looseness and wear. It is important that this pin should be a tight fit, otherwise it may work out and injure the cylinder walls. A loose piston-pin may be due to the set-screw becoming loose, or it may be caused by wear. In the latter event, the pin should be replaced with a new one of the proper diameter and length. Thoroughly clean the piston, rings and pins with gasoline.

How the Valves Should Be Ground—The valves should be next attended to, as the chances are they need grinding. This is not a difficult task, and if the directions are followed the amateur should be able to turn out quite as good a job as the garage. Procure emery of the grade known as 120, put a small quantity in a saucer, and add kerosene (gasoline should not be used, as it evaporates too rapidly) to make a thin liquid paste. Then add a few drops of heavy lubricating oil to give the mixture a little more body. Put a small amount of the grinding mixture on the face of the valve and its seat, insert a screwdriver in the valve slot and rotate in its seat. This is easiest done by rolling the handle of the screwdriver between the palms of the hands, first one way, then the other. Do not use a greater force than is necessary to turn the valve in its seat. Lift the valve up occasionally, turn it partly around in its seat and rotate as before until the valve and its seat show a bright ring the entire way around. Renew the grinding mixture occasionally, but remember that a small quantity of emery and plenty of kerosene and oil will not only make a smoother job, but will also do it much more quickly than a large amount. Finally, the valves and their seats should be washed with gasoline to remove every particle of the grinding mixture.

The camshafts in most cars are removed by taking off the cover of the case which encloses the timing gears and pulling the camshafts through this opening. All modern cars have the crankshaft gear marked, and another mark between the two teeth of the timing gear on the camshaft. When assembling, the single marked tooth should be inserted between the two teeth as designated. Breakage or undue wear of the cams is a matter which only the factory experts can handle.

Cleaning the radiator of grease or any scale that may have accumulated is best done after the car is reassembled and in running order. The writer's method is to dissolve one-half pound of lye in a bucket of water, stirring until dissolved. This should be strained and the radiator filled with the mixture. Run the engine for five minutes and allow to stand for a quarter of an hour, then drain off the mixture and fill up with clean water; run the engine for a couple of minutes and drain off again. Three or four rinsings should be given to remove all the alkali.

The gear-box cover should now be removed and the gears examined. As most transmission systems are fitted with annular ball bearings, only a good cleaning to remove old grease will be required. In case any gears are badly worn and their edges chipped, they should be replaced with new ones.

The clutch may next be taken down. The exact mode of procedure differs in different car clutches. In most cars using clutches of the multiple-disc type it may be removed as a unit; in other forms, the shaft connecting the shifting sleeve may be uncoupled, which gives sufficient room between clutch and gear box to take the cluch apart. If the latter is of the cone type, it may be found that the leather face is badly worn and that a new leather is necessary. This is not a very difficult job, but requires painstaking work.

Replacing the Leather of a Cone Clutch—Remove the old leather by cutting off the rivets on the underside and driving the rivets through to the outside. Keep the old leather and use it as a pattern by which to cut the new piece. It will be much better, however, to purchase from the factory a new leather of the proper width and thickness. As a new leather will have considerable "give," it must be stretched tightly over the cone. First cut one end of the leather square and fasten it to the cone with two rivets. The other end should not be cut at this stage of the work, but brought around to meet the fastened end, and, after tightly stretching it over the small end of the cone, fasten it with a single rivet. Then force the leather up onto the cone, drill out and countersink the holes and rivet up securely. The only knack in the operation is to keep the leather tight that it may be a snug fit on the cone. A loose leather will, naturally, be a dead failure. After the leather has been forced into its place the uncut end should be trimmed to make a good joint. Any unevenness may be trued up with a file. The new leather will readily absorb several applications of castor oil before it becomes smooth and pliable.

Care should be taken that the rivet heads are countersunk below the surface of the leather. In case they work flush, owing to the wearing down of the leather face, they should be reriveted. The "biting" or jerky action of a cone clutch may often be traced to the rivets working out, and this will frequently prevent the clutch from being readily disengaged. Reriveting will prove an effective remedy in this case, and considerable additional service may be had from the leather before it wears down to the rivet heads.

The differential gear should be tested with a view to locating any wear or side play. This may be done by jacking up the rear axle and shaking one wheel forward and backward while the other is held stationary, and noting how far the wheel must be turned before the movement is taken up by the flywheel of the engine. Any noticeable play will generally be found either in the center pinions or studs of the differential gear, in the large and small bevel gears, in the clutch sleeve, or in the universal joints. The differential gear and live axle of modern cars seldom give trouble if kept properly lubricated, and the car's mileage should run up into many thousands before any considerable amount of play is evident. The joint pins of the propeller shaft may become loose through wear, in which case a knocking noise in the transmission gear will indicate the cause and location of the trouble. These pins may be readily replaced with new ones at small cost. If the play is found in the bevel gears, the small gear should be adjusted to mesh deeper with its larger mate. This may be done by means of the adjustable locking ring or by inserting a washer of the proper thickness. It may be found, however, that no adjustment is necessary, and a thorough cleaning with gasoline to remove all oil and grease will be all that is required. The case should then be refilled with the quantity of oil and grease recommended by the manufacturers.

Oil pipes or "leads" which conduct the oil to the bearings should be removed and all old oil washed out by forcing gasoline through them. Care should be taken that the passages of all oil leads are clear and unobstructed. The oil pump should be taken apart and given a thorough cleaning with gasoline. The sight feed lubricator on the dash should also be cleaned out and the glasses wiped and washed out with gasoline.

Look at the Steering Gear and Brakes—The steering gear is a very important part of the car, and, as the safety of the occupants may be endangered by any binding, the reader should give it even more careful attention than the other parts. The gear should be taken down, given a thorough cleaning and examined for possible wear. In case the steering action is stiff and the wheel turns hard, the ball joint may be out of adjustment due to wear; the steering link may be bent, or the cause may be insufficient lubrication. If there is any considerable amount of backlash, the cause may be looked for in the joints of the levers, in the swivel pin, in loose bearings, or in wear of the worm and sector. Another common cause of backlash is often found in the wheels, which work out of alignment. It is essential that all moving parts of the steering gear be well lubricated.

The distance rod is easily bent, which throws the front wheels out of line. This is a common cause of "side slip" and rapidly wears out the tread of the tire. The bent rod should be uncoupled and carefully straightened. On many cars, however, the rod is designed to be bent, in order to clear other parts.

Each wheel should be removed and examined at the hub to see if the spokes have become loosened through shrinkage. Although this is not a common fault, it is, nevertheless, worth looking for. If slightly loose, tighten up the bolts which secure the two side flanges together, clean out bearings with gasoline and renew any ball or roller which is found damaged. If rust has accumulated, scrape or sandpaper it off (a painter's wire brush is a handy tool), and when perfectly clean coat the rim with beeswax. This may be applied with a clean paint brush if the wax is heated to a liquid state. This will effectually prevent further rusting of the metal, and will do much to preserve the life of the tires.

Examine the brakes to ascertain if the lining is in good condition. If worn, the old lining should be replaced with new. If the brakes are of the internal-expanding type, the shoes may have become worn, in which case they should be renewed. Toggle joints and adjusting nuts should be inspected and any looseness taken up. Brakes should be adjusted on the road, as any improper adjustment of the equalizer bar will have a strong tendency to make the car skid. Both brakes should be adjusted alike, that the braking force applied by the equalizer may be transmitted to the wheels equally.

The tires should be cleaned of the old chalk on the inside of the shoe. If they are badly worn on the treads, but otherwise in good shape, send them to the factory to be retreaded. A tire should never be kept on the car after the rubber tread wears down so as to expose the fabric. Any small cuts and holes should be washed out and filled with rubber solution.

Inner tubes should be tested for leaky valves and patches attended to at once. The old casings and tubes may be made to give considerable additional mileage by using them on the front wheels, where the strain is not so severe.

Caring for the Electrical Apparatus—Look over the electrical plant and replace worn wires with new. Clean out the timer with gasoline and lubricate with light oil. The magneto need not be taken apart, as it will probably only need a little surface cleaning, a few drops of oil, and the amateur had better not meddle with its internal mechanism. The storage battery should be examined, and if the brown deposit collects in any quantity at the bottom, the electrolyte should be poured out into a glass bottle and the battery washed out with clear water (rain water preferred). Clean the top of the battery and make it a point to keep it clean and free from acid. Clean the terminals of any corrosion and see that the air vents are not clogged up. If the accumulator has been neglected, either in the electrolyte having been allowed to get below the proper level or in not giving it the regular monthly "charge," it may get a bad case of sulphating.

To get the battery into its normal condition, empty out the electrolyte and wash the case thoroughly with soft water. Pour in only about seven-eighths of the acid solution and fill up with distilled water to cover the top of the plates. The battery should then be charged with a low current until the plates are restored to their normal condition. If very badly sulphated, the white coating should be washed off with a rag, and in case this fails to remove it, scraping must be resorted to. If the electrolyte is not sufficient to cover the top of the plates, fill up with distilled water so that the liquid will just cover them. The specific gravity of the electrolyte should not be less than 1.150, and, although varying somewhat, a hydrometer reading of 1.250 is recommended. This is approximately 1 part of sulphuric acid to 4 1-2 parts of water, which will be found sufficiently accurate if no hydrometer is at hand. If the electrolyte should test lower than the first figure, add pure sulphuric until the 1.250 mark is reached.

In case the plates are broken down or "buckled," or if the paste has dropped out of the pockets in the grids, the accumulator should be sent to the manufacturers for repair. In some accumulators the liquid is not used, but a jelly made of silicate of sodium and dilute sulphuric acid takes its place. If your battery is of this type, it is well to remember that the jelly must be kept moist on the top, and as the emulsion becomes dry a little water should be added to replace that which is lost through evaporation.

The contact points of the coil will probably require adjusting. This is very easily accomplished by trimming up the points with emery paper. Do not rub away the metal unnecessarily, only removing enough to true the points so that they make a good contact. In adjusting the vibrator, remember that a light tension is much better than a stiff tension. A light flexible vibration with a moderately high-pitched buzzing note will not only give a better spark, but will keep the points in better shape. A heavy tension will make the coil less responsive and will pit the contact points and exhaust the battery more quickly. As a coil will render the most efficient service only when the vibrators are adjusted as nearly alike as possible, a special ammeter is often used to determine the current consumption of each unit. The ammeter should show a reading of 6-10 amperes.

Assembling Often the Most Difficult—In assembling the car the engine had best be put together first. When putting the pistons in their respective cylinders see that the splits or joints in the piston rings are not in line, but are spaced evenly around the piston. See that all parts are thoroughly clean and that no grit or stray strands of waste happen to be caught on any projection. All nuts and bolts should be screwed tight and the jaws of the wrench should be properly adjusted to them, that the corners of the nuts and cap screws may not be rounded off. Insert the cotter pin after each nut has been screwed home. In joints where packing is required the old packing may be used if it is in good shape. Joint faces should, of course, be perfectly clean. A stout grade of manila wrapping paper soaked in linseed oil will make an excellent packing for crankcase and other joints having a good contact surface.

While the engine is being reassembled it will be found advantageous to check up the valve timing. To do this, turn the fly-wheel until the inlet valve plunger of No. 1 cylinder just touches the lower end of its valve stem. At this point the line on the fly-wheel indicating "Inlet No. 1 Open" should coincide with the pointer on the engine base. If the contact between the valve stem and the plunger is made before the mark on the fly-wheel lines up with the pointer, the valve opens too early. In most cars the adjustments may be made by the screw cap and lock-nut on the plunger. As the valve stems are lowered by repeated grindings of the valves, the plungers require adjustment occasionally to compensate for this movement. Insert a piece of paper between plunger and valve stem, and by lightly pulling on the paper the time of contact and the moment of release may be determined to a nicety. When the paper is held tightly, a good contact is assured, and the moment the paper becomes loose and can be moved about, the contact is broken. In many cars the reference or index mark on the engine bed is omitted; in this case the markings on the fly-wheel must be brought directly to the top. The other inlets and the exhaust valves should then be similarly checked up and adjusted.

Most cars base the valve setting on a 1-32-inch clearance space between valve stem and plunger rod when the valve is closed. This may be taken as the minimum amount, and should not be increased. A larger amount of clearance will cause the exhaust valve to open too late, and, the exploded gases not being entirely expelled, the power of the motor will be impaired. This clearance is necessary to allow for the expansion of the valve stem when it becomes heated.

Too much stress cannot be laid on the necessity of going about the work in an orderly and methodical manner. A mechanic who leaves parts lying about carelessly will rarely be found a good one, and certainly he is not a proper model for the amateur to copy. With the proper circumspection, then, and with a little "horse sense" in applying the directions to his particular make of car, the amateur owner should have no difficulty in making a good job of overhauling, thus bettering the condition of his machine and at the same time acquiring a valuable stock of knowledge for the future.

SOME INFORMATION FOR THE MAN WHO DRIVES

Examine the Car Below the Frame—Most autoists are content to make all their inspection of the car and its mechanism from above, and rarely give more than a casual glance below the frame except when trouble occurs. On cars fitted wtih pressure-feed on the gasoline, the piping should be frequently inspected, on account of the danger from fuel leakage. Such inspections should be made when the motor is stopped and the pressure still turned on. The tank should be gone over for leaks arising through the opening of its seams from vibration, or the loosening of the union connecting the fuel lead with the tank. The lead and its connection to the carbureter should also be examined for leaks and abrasions due to rubbing against other parts of the mechanism. If any such are found they should be immediately repaired. Twine, tire tape or rubber bands will act satisfactorily as fenders to prevent further mischief. Unions which can not be made tight by screwing up should be taken apart and the male connections coated with soap or red lead, which will render them tight for a considerable time.

After going over the fuel system, the brake rods and steering connections should be examined for loose joints and broken oil and grease cups. Grease boots on the drive-shaft joints should be seen to be sound and filled wtih grease. A cleaning out of the dirt from the interior of the mud-pan will often reveal lost cotter pins or nuts and tend to a more agreeable handling of the draincocks, carbureter and filter. This time will be well spent when the chances of fire or accidents arising from faulty steering or brake connections are taken into account

When the Jack Is Missing—Should the jack be missing or broken, an efficient substitute can be rigged from a large stone or a number of bricks piled one on another until the height is sufficient to life the wheel from the ground. Having gotten the stone or piled the bricks one of the floor-boards can be utilized as an inclined plane and the car backed up until the axle rests on the top of the pile. When the work has been performed, the axle will have to be pushed off the pile, but as the drop is inconsiderable no harm can come to the tire. Where stake-and-rider fences abound, one of the rider timbers can be utilized as a lever with a stone as a fulcrum to raise the axle, supporting the latter with another stone during the repair and gently easing down the axle when ready to proceed.

Where the Owner Himself Takes Care of the Car—Beautifully polished brass and nickel work look smart on any car, but it requires considerable attention to have the work always in ship-shape condition. With the autoist who has a chauffeur or garages his car no thought need be given to the matter, but he who does all the work on his car has, as a rule, little time to spare on polishing and so his bright-work belies its name. Autoists, therefore, who purchase a car will find that it will pay them to have all nickeled or brassed parts given a coat of man-of-war gray or oxidized-bronze finish so that only at long intervals will it be necessary to give the parts more than an occasional wipe. The time and labor thus saved will be well worth the money spent.

Benefits of Night-Driving— Driving at night is beneficial in a number of ways. A drive at night after the day's work clears the mind and fills the lungs with fresh air. The rapid passage of the car creates a sense of buoyancy and the reaction causes a feeling of drowsiness which makes the autoist sleep like the proverbial top. Especially is this the case with nervous persons or those whose occupation keeps them indoors for the greater portion of the day. This applies to driving in the spring, summer or autumn, as winter driving at night in an open car is far from pleasant, and may subject the riders to neuralgia.

LETTERS INTERESTING

TWO CYCLE POWER OUTPUT

Editor THE AUTOMOBILE:

[1,995]—Referring to your answers to questions number 1,986, page 316, August 19th issue, comparing two and four-cycle motors, your statement that "The very best two-cycle engines will not develop much over one-fifth more power than the same sized four-cycle," does not do justice to the perfected type of two-cycle motor. For example, take a two-cylinder, four-cycle motor of 4 1-2-inch bore and stroke, and the power limit is about 12 horsepower. For comparison, take the Atlas, two-cycle motor, with which I am well acquainted, and the two-cylinder engine of 4 1-2-inch bore and stroke shows 22 horsepower, and the comparison holds good in the three and four-cylinder types, actually showing at least 60 per cent more power than the best four-cycle motor of equal dimensions.

A little investigation will show you other good two-cycle motors that can easily disprove your statement as to power. Your comparison for the greater part was unbiased and very clear. My taking exception to your last lines is due to the fact that most of the prejudice against the two-cycle motor has been due to ignorance of actual facts and of the increased efficiency of the present-day motors, and misstatements of any nature, in a widely read paper such as "The Automobile" should be revised, at least when involving important interests.

THOMAS E. DENTON.

Newark, N. J.

Replying to the above criticism, attention is called to the description of the Thomas cars in the same issue as mentioned, page 319. In this is given a chart of the actual power of a 4 1-2-inch diameter engine as plotted from accurate tests. This shows that the power which can be developed from six cylinders of that size may easily reach 64.2 horsepower. Now, the A. L. A. M. rating formula gives this sized engine a power output of but 48.6. So, the actual engine exceeded the rating formula by 32.1 per cent. Since this is not an unusual motor, it is fair to assume that any other of the same general dimensions would do equally well. So, taking the A. L. A. M. rating for a two-cylinder, four-cycle engine of 4 1-2-inch bore from a table, it is found to be 16.2 horsepower. Now, adding to this the increase of 32.1 per cent, which it is possible to obtain, the result obtained is 22.4. As compared with the power which you say can be obtained from a two-cylinder, two-cycle engine of this same size, there is a slight increase in favor of the four cycle of 1.8 per cent instead of the one-fifth or 20 per cent the other way which we generously allowed.

If it is a fact that more power can be obtained from the two-cycle engine of any given size, why is it that none of the two-cycle people ever give out accurate and bona fide test results like the one spoken of above, instead of contenting themselves with claims as to wonderful power output. The writer is very much interested in this subject and has searched long and faithfully for data to prove what the two-cycle power output really was. After three years searching, it must be confessed that the only information came to light very recently and that was from England and concerned a radically different construction of two-cycle engine, which could not well be compared with the ordinary four-cycle engines.

A power curve of this English two-cycle motor, two of them in fact, as compared with an equally well-built English, four-cycle engine of similar size, showed up as follows: Both two-cylinder, two-cycle engines developed the same maximum power, which was 13 1-2 horsepower at 950 revolutions, with a rapidly falling torque curve, the greatest power being taken at the speed mentioned, higher speed giving less power. Now, the four cylinder, four cycle, which ought to be halved as a source of comparison, gave on the testing stand (the same in each case) 30 1-2 horsepower. This was on a constantly rising torque curve, which showed or appeared to show, that much more power would be developed at still higher speeds. So, taking half of this modest four-cycle output for comparative purposes, we get 15.25 as compared with 13.5 for the two cycle. This, you see, is 13 per cent in favor of the four cycle rather than 20 per cent for the two cycle.

While not desiring to start a controversy on this subject, the writer would say that this lack of data, combined with the results from what little information is available, has led him, personally, to think that the two cycle will not give as much power as a four cycle of equal size, number of cylinders, and similar construction. In this, he is like the man from Missouri, willing to be shown.

VERY ELUSIVE MISSING

Editor THE AUTOMOBILE:

[1,996]—I am taking care of a * * * * * * touring car, the engine of which, when it runs under heavy load or at high speed, disengaged from the car, will run perfectly; but when running at low speed and idle, will run almost entirely on one cylinder. The car has a * * * * * * * coil and shows a very good spark on both terminals when pulled off from the spark plug. The spark plugs are in good condition, and the compression is good. I have adjusted the carbureter in different ways and the miss cannot be stopped. Now will you advise me through "Letters Interesting and Instructive" where the trouble may be. S. S.

New Ulm, Minn.

The trouble is in the wiring. You have one of these faults: loose wire or connection: broken-down insulation, or broken wire. The first being the case, the wire is shaken out of a connection or circuit by the running and consequent jarring of the engine when under load, which is not the case when turning over quietly without load. This applies equally well to the third case or broken wire, which holds together, perhaps through the strength of the insulation, when running slowly and quietly.

The broken-down insulation only shows itself when the spark is required to jump a large gap through compressed gas, as in the cylinder, whereas it will not show on a small gap outside of the cylinder. The remedy is to renew the wiring.

ELECTRICS' POPULARITY

Editor THE AUTOMOBILE:

[1,997]—Without wishing to be too critical of your editorial in the July 15 number, permit me to correct the apparent erroneous impression that the revival in the use of electrics has been "of late." The increase has been a continuous one for a number of years, though many have not realized that any change was taking place.

As to leading electric vehicle manufacturers into the "promised land," apparently the writer of your editorial is not familiar with the past history and the effect that the premature announcement of the Edison battery had on trade in 1903 and 1904 and various occasions afterward.

We are all anxious that Mr. Edison should do what he has himself expected, though few have any hopes of such accomplishment as the press heralded. Indeed, it has been said that Mr. Edison never authorized the exaggerated claims which have been made.

The Edison, or any other battery which is better than that which we now have, will be welcomed, but if any manufacturers are waiting "with bated breath" it is probably in wonderment as to how many new editorial writers will take occasion to dilate on the possibilities which offer such opportunities for imagination.

Probably very few manufacturers will again invest much capital in special models to take the Edison battery until the scrap castings and patterns from former models built for that purpose and charged to profit and loss are forgotten.

And as to the hose-pipe tire, your reference is misleading. Except for the very low voltage, light car of the Baker, no one has, except for occasional test or experiment, used a thin wall hose-pipe tire for years. All of the so-called electric tires are made in detachable form and have been for a number of years. They can hardly be called thin walled, but are rather flexible walled and made of finer fabric and more pure rubber than the gasoline type of tire. When properly made they seem to have just as great durability. HERBERT H. RICE,

THE WAVERLEY COMPANY.

Indianapolis, Ind.

WHY NOT USE BROKEN CHAIN

Editor THE AUTOMOBILE:

[1,998]—In the issue of Aug. 19 of your paper and on page 315, under the heading "Chain or Shaft," the following statement occurs: "If one of the chains break, on a double chain driven car, it is helpless, and must be towed home."

I don't see it. Why not use the broken chain, a piece of wire, or a bit of rope to fasten the sprocket on the end of the counter shaft on the side of the broken chain to the frame of the car and drive home with the other wheel? It has been done and so can be done again.

Fredonia, N. Y. A. WILSON DODS.

The above wayside repair is not only a good and practical one but will save the owner of a chain-driven car, in a similar fix, from the annoyance of being towed home. The idea is to fasten the counter-shaft on the broken chain side so that it cannot rotate. In this case, through the action of the differential, the engine will drive the other shaft in the regular manner. It will thus be possible to proceed home but at a reduced speed. As blocking one shaft of the differential in this way will cause the other shaft to rotate at twice its usual speed, it will be necessary to use the low gear, and difficulty may be met on hills.

ANSWERED AND DISCUSSED

LONG STROKES DISCUSSED

Editor THE AUTOMOBILE:

[1,999]—I have for years stood for a short stroke engine in order to gain the light weight and compactness needed in auto work, and I regard the use of long strokes as a mistake for daily use. For the racing service for which they were designed I have nothing to say. I feel that your answer to Mr. Hickman (1,949) is not full enough to make clear the facts. The long stroke engine cannot make so many turns per minute as can the short, because the limiting thing is the piston speed. Thus a 4-inch stroke can turn its shaft 50 per cent faster than a 6-inch stroke engine and not exceed the same piston speed. This means that the short engine is 50 per cent more flexible. Your statement that less reducing gearing is necessary is hardly correct. With a flexible engine there is less need for speed changes than with an engine which is incapable of making those changes by throttle. But the racing car has little need for speed changes. It is not subjected to deep mud, thick traffic, steep hills and such things as make necessary the use of low gears on a car for daily use. It therefore is not at a disadvantage if it has a less flexible engine, but, on the contrary, gains if its engine of a given size can be made to work more efficiently. But what is best for the racing man is not of necessity best for the road user. I saw comfortable road bicycles converted into comfortless racing things and then the public, disgusted, gave up the style of using the cycle. Racing rules should limit power by limiting piston displacement and let the designer make the engine the way he thinks it ought to be. This developing an industry by laws made by people who know little or nothing of the subject can never be productive of best mechanical results.

CHARLES E. DURYEA.

Reading, Pa.

Since long-stroke motors may be made to turn over as slow as 250 revolutions per minute, which is as slow as it is ever necessary to run the engine, and engines of a stroke equal to twice the bore have actually turned over as high as 1,800, it seems as if the claim of lack of flexibility is not well founded. The Arrol-Johnston 4-inch engine developed its best power from 1,500 revolutions on up to 2,400 revolutions, at which latter number of turns, the power output was in excess of 72, as compared with the rating for this engine (a four cylinder, four cycle) of 25.6 horsepower.

It seems as if this denoted superior rather than inferior flexibility, and sufficient power to entirely eliminate the gear box, which is going "less reducing gearing" one better. At ordinary speeds, this motor will develop more power than an ordinary short or equal stroke engine, so that for the same power requirement it may be run slower. In emergency cases, when a lot of power is suddenly required, instead of gearing up as in the short-stroke motor, the throttle is opened, and advantage taken of the superior power ability of the longer stroke. In this respect it is somewhat similar to the steamer, which is able to develop an enormous amount of power for a short time, with this essential difference in favor of the internal combustion engine that it can keep on developing the extra power for an unlimited length of time.

If an average power requirement be taken, it will be found that the long-stroke unit develops it, or meets the requirement, with a smaller rotative speed. This means that the gear reduction at the rear axle may be less whatever the speed may be. This lesser reduction at the rear axle means that the driving bevel may be larger and consequently stronger, or on the other hand, the driven bevel may be smaller without reducing its strength, since it is already very large. The size of this governs the road clearance which may, by this latter method, be materially increased. Similarly, this reduction of size of the driving gears reduces the size, weight, and cost of the bevel gear and differential housing. In this way, the whole rear construction is reduced in size, cost, and weight.

It is the firm belief of the writer that the engines of the future will be of very small bore, taking up very little space. In place of the present sizes, a long stroke and superior construction will be relied upon to give a very much higher power output than we now obtain. As to the linear piston speed, if that is satisfactorily taken care of in racing cars, in which the very highest speed is maintained for upwards of ten hours, there is no doubt that touring cars will be well cared for.

The gain from these smaller bore but longer stroke engines of the future will be threefold; lessened space, devoted to the power unit; greatly reduced weight, despite longer stroke, and as a factor of the other two, lowered cost. The light weight of both engine itself, and rear consctruction, as previously pointed out, will evolve more mileage from the tires, and other similar parts, resulting in making the upkeep less.

This tendency towards the small engine with long stroke is noticeable in a mention of a few of the latest productions of the other side. Thus, taking those most handy we find: the new Mercedes (German) with a four-cylinder engine of 80 mm bore (3 1-8 inch) by 130 mm (5 1-8 inch) stroke. Delaunay-Belleville (French) has just brought out a new little car equipped with a four cylinder 85 mm (3 3-8 inch) bore by 120 mm (4 3-4 inch) stroke. So, too, in England, the latest Sunbeam car has an engine of 95 mm (3 3-4 inch) bore by 135 mm (5 5-16 inch) stroke. This latter would rate at 22.5 and actually developed on test 54 on a continually rising torque curve. Doubtless, the sales record of this car would show how many motors of 5 by 5 and larger sizes were put out of business altogether by the newer and smaller car, with the more powerful long stroke (1 to 1.42 ratio).

COMPRESSION—EXPLOSIONS

Editor THE AUTOMOBILE:

[2,000]—Will you please answer the following through "Letters Interesting and Instructive":

1. About what pressure is exerted per square inch in a gasoline engine cylinder when the charge is exploded?
2. What effect would it have upon a four-cycle engine if the charge were to be exploded just before the completion of the compression stroke (of course sparking of the ignition would be a little earlier than the explosion)?

A. F. C.

Fitzwilliam, N. H.

In answer to your first question, this quantity varies from 50 up to about 75 pounds per square inch for the compression pressure, which is multiplied by four (roughly) by the explosion. That is, the explosion pressure varies from 200 up to 300 pounds per square inch. These figures are for normal engines intended for ordinary touring purposes, and do not take into account the cars especially built for racing and similar purposes in which the compression pressure may go as high as 100 pounds per square inch, and the explosion pressure to more than 400 pounds.

Your second question describes average and daily automobile practice, if you but knew it. That is, in engines now used, the spark is made to jump a measurable amount before the engine reaches the upper dead center, or as you put it, before the compression stroke is completed. The lag in the propogation of the flame through the mixture, with the consequent lag in the expansion of the exploded gases, is so great that at the speed of the motor, the expansion does not begin to drive the piston down until it has passed the center. This action only occurs at high speeds, when the rotative speed of the engine enters into the question, with a favorable action. At slow speeds, the spark is made to happen at points further and further ahead on the stroke, until the extreme point is reached at the starting position. This last is usually fixed at 15 degrees of the crankshaft after the upper center.

From this point, the angle gradually decreases with increasing speed, until it reaches and passes the center point. Beyond this, in many cars, it may continue up to 20 or more degrees past the center. In point of fact, a number of prominent and successful French designers exceed this very much, as will be noted by the short table appended. In this the rotative speed (maximum) is given and the angle is that of farthest advance before center measured on the crankshaft:

Rochet-Schneider	20 degrees	1,400
Aries	20 "	1,500
Darracq	21 "	1,500
Vinot-Deguingand	27 "	1,500
Brouhot	30 "	1,300
De Dion	30 "	1,400
Unic	30 "	1,650
Peugeot (Beaulieu) ...	31 "	1,400
Sultan	32 "	1,600
Renault	33 deg. 30 min.	1,600
Brasier	34 degrees	1,350
Cottin-Desgouttes	38 "	1,300
Peugeot (Paris)	38 "	1,300
Cornilleau-St. Beuve ..	43 "	1,300

These are arranged in order of advancing spark advance, and it will at once be noticed that the speeds of rotation do not follow in a natural increasing order.

AERONAUTIC EXPLANATION

Editor THE AUTOMOBILE:

[2,001]—I have been considerably puzzled by some of the aeronautical terms that seem to be coming into general use. For instance, Bleriot's machine is called a monoplane, which one would naturally suppose to mean that it had one plane or supporting surface, but a description of this same machine says that it has two wings. I am unable to reconcile these statements with any degree of satisfaction to myself. I am also unable to see what improvement the Wrights have made in aeroplane construction. The pictures I have seen of their machines do not look any different from the others, except that they do not have any wheels. Can you explain what their patents are based on? Perhaps some day the different types of airships will be as familiar as shaft-drive and chain-drive, but meanwhile there may be many of your readers who are in my predicament. I am sure that an explanation of these details will be of general interest. OLD-TIMER.
New York City.

The sudden leap into prominence of the different sorts of flying machines has certainly introduced an abundance of new technical terms into the language, and we are of your opinion that these may be confusing to a great many who are really interested in this subject and would like to keep abreast of the times in it. We already have in course of preparation an article which will treat this subject thoroughly, to appear in a near issue of THE AUTOMOBILE. Meanwhile we shall be glad to go into the subject at some length.

The basic distinction in all flying machines is between lighter-than-air and heavier-than-air types. The former rise by the direct action of gravity until they reach a level where their weight equals the weight of the volume of air they displace. The latter rise by the action of the pressure of the air beneath their rapidly moving surfaces.

The lighter-than-air class includes all balloons, as well as the vacuum airships sometimes proposed. Dirigible balloons, which are those popularly called airships, have been made familiar by Zeppelin in Germany and by Knabenshue, Baldwin and others in this country.

Of the heavier-than-air class, the original form is simply the kite. The only difference

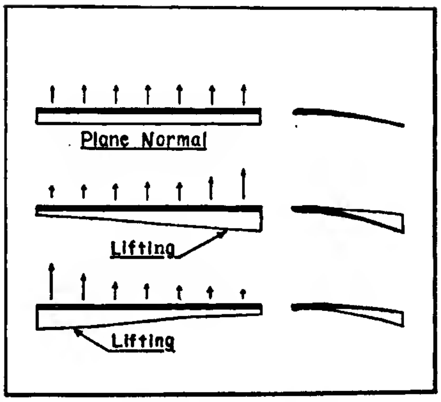

Diagram of Flexible Planes Used by Wrights

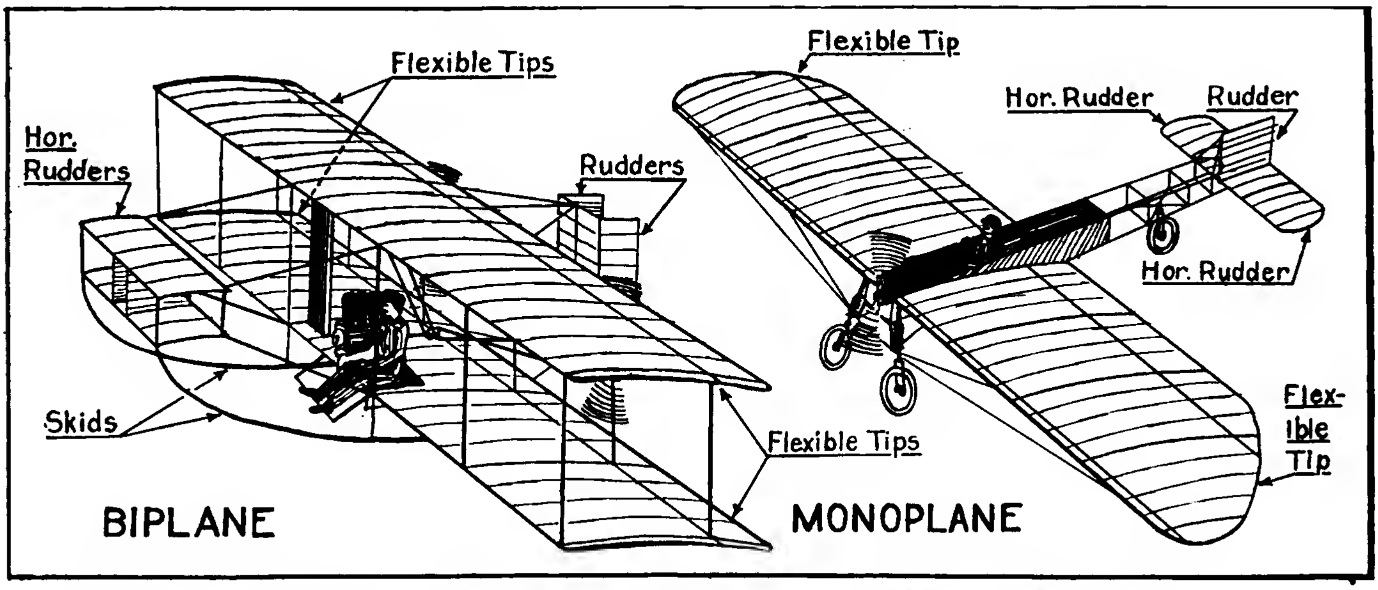
between a kite and an aeroplane, except for size, is that the kite is usually held stationary in a current of air, while the aeroplane moves itself and provides its own air currents. The supporting surfaces of the aeroplane, corresponding to the body of a kite, are usually called planes, though they are in reality curved. The terms monoplane and biplane may best be explained, however, by taking plane in its other meaning of "level"; thus a monoplane has its supporting surfaces in one plane or level, and a biplane in two planes.

The Wright brothers have done a great deal of experimental work, the results of which have been incorporated into their machines in many ways, some of them no doubt so subtly as to escape even expert notice. The principal feature of their machine, however, and the one on which their strongest patent is based, is the warping-wing principle. The purpose of this is to maintain the lateral equilibrium of the machine. Any sidewise tipping, such as is often caused by an irregular gust of air, cannot be corrected by any form of rudder, as the machine has no sidewise velocity. It is like a ship without "steering way." The Wright method of dealing with these deflections is to make the tips of the planes or "wings" flexible, so that at the will of the operator they can be bent to meet the air currents at a greater or less angle. The greater the angle, within limits, the greater is the lifting effect. Then if one side of the machine sinks down, the wing tips on that side are bent to secure a greater lifting effect, and that side is raised until the machine is again on a level. In practice, the levers and wires controlling the twisting of the wings are interconnected so that when the angle of one wing is increased, that of the other is lessened; thus the aeroplane is brought to the desired level by lifting the lower side and lowering the upper side.

Other aeroplanes, notably that of Curtiss, use small movable auxiliary planes, one on each side, to obtain the same result. These planes may be clearly seen in the picture of Curtiss' machine in THE AUTOMOBILE for August 19, page 301. Bleriot on his monoplanes uses the Wright method.

The use of skids instead of wheels on the Wright aeroplane, as well as the starting track and the tower with the falling weight to give the machine its initial impulse, are merely details. It might just as well—better, in the opinion of most experts—be made with wheels, and get its start by running along the ground.

None of these machines incorporate any device for maintaining stability automatically; the operator must not only steer in the usual sense of the word, but also he must control the elevation and prevent his craft from being tipped over to either side. Undoubtedly the greatest development in aeroplane design will be the invention of some means of keeping the machine on an even keel and headed in its original direction without the intervention of the operator. Such a device, successfully applied, would make aeroplaning as safe as automobiling, and as easy to learn. The most promising form appears to be some application of the gyroscope; at any rate, this is a great chance for some clever inventor.



Aeroplanes of Wright and Bleriot Types, Showing Arrangement of Flexible Tips and Horizontal and Vertical Rudders

EFFECT OF AUTOS ON ROAD SURFACES

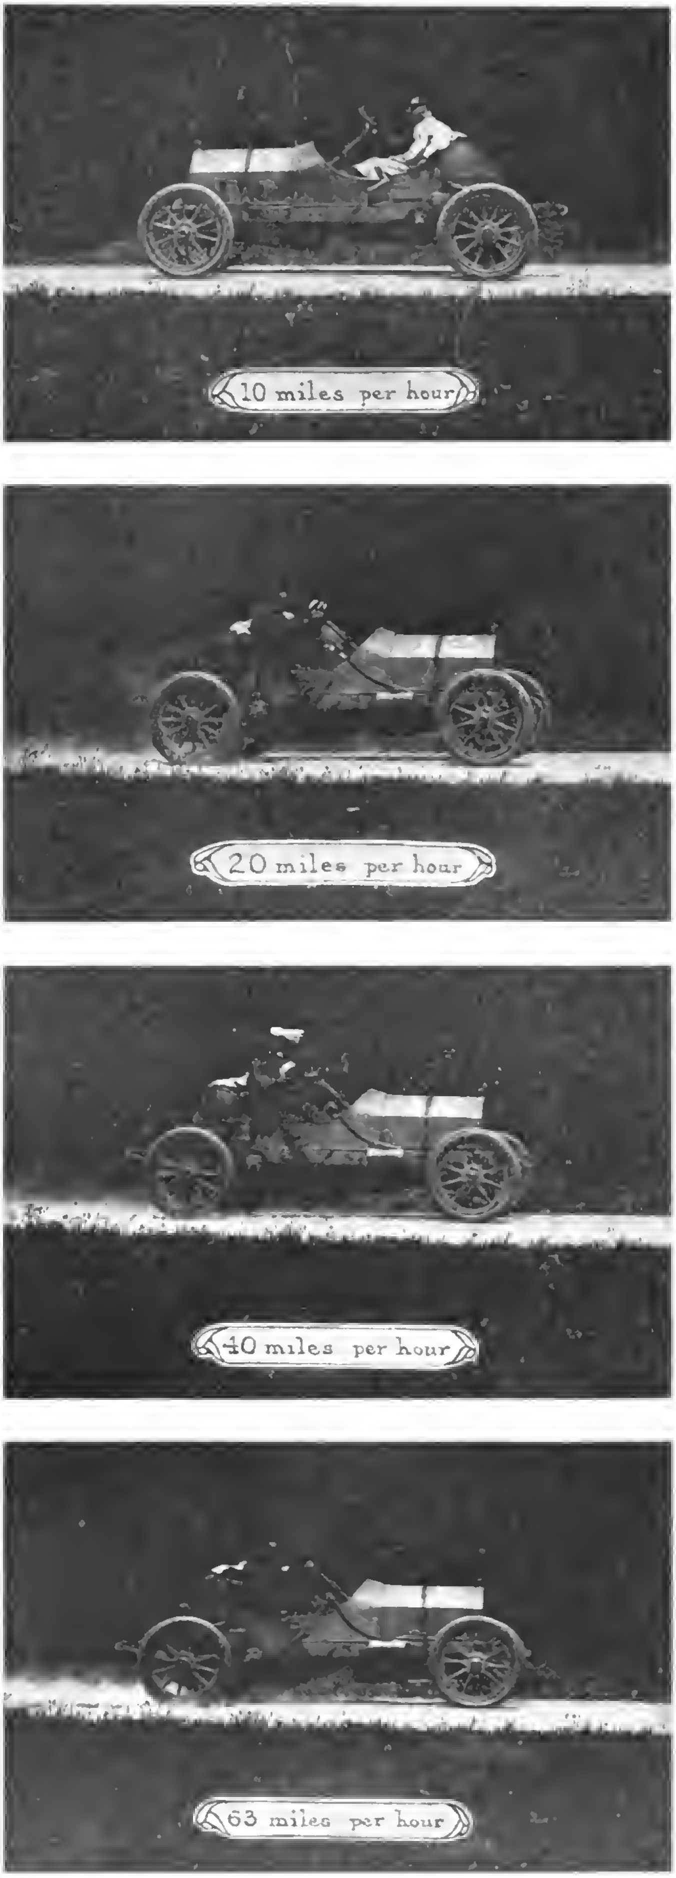
WASHINGTON, D. C., Aug. 30—The Department of Agriculture, through its bureau of Good Roads, has begun a series of experiments designed to show the effect of automobile traffic on the surfaces of highways. The accompanying photographs illustrate the results of the first tests, which were made on what is known as the Conduit Road. This highway extends through the northwest suburbs of Washington and is of the ordinary type, having a stone base surfaced with ordinary macadam. The automobile used had a speed capacity of rather over a mile a minute, and provision was made for timing it over a measured stretch. By the side of the road a camera with a shutter giving an exposure of but the two-thousandth part of a second was placed where a direct view of the roadbed and car could be secured.

The four different views taken are reproduced with this article. At a rate of 10 miles an hour no dust whatever was visible in the picture, apparently proving that this rate of speed has no effect on the surface of the highway. At 20 miles an hour a small quantity of dust was raised, seemingly by the action of the rear wheels alone. At 40 miles an hour a slight increase in the amount of dust raised can be observed. The last photograph, taken at a speed of 63 miles, clearly shows that the friction was very great. As might be expected, the front wheels of the car seem to have a very slight effect; no dust rising behind them except in the last trial, when a faint haze may be discerned.

Rear View of the Latest European Dustless Body

DUSTLESS BODY AT LAST DISCOVERED?

LONDON, Aug. 25—In a recent issue of THE AUTOMOBILE there were illustrated several examples of the "flush sided" or torpedo body, now so popular in England. Another type, embodying some new features, is shown in the accompanying photograph. The chassis is a standard 23-30-horsepower Austrian Daimler, with a wheelbase of 123 inches. The side view of the body reveals merely the ordinary torpedo construction, with the usual high doors. The novelty consists in the construction of the rear portion, which has a clear opening from the underpart of the body. It will also be noticed that the rear panels are curved around in a peculiar fashion. Both these features have been adopted after lengthy experiments by the builders, the Max Graddon Company, with a view to lessening the dust-raising qualities of the car. It is found that the vacuum usually existing behind the rear seats, which is the most potent cause of dust-raising, is entirely obviated by the provision of the "tunnel" arrangement, as the air sweeps freely around the corners of the seats. Observation fully confirms the maker's claim to almost complete dustlessness. An additional advantage claimed is that the car is considerably faster with this body than with a body of standard type and the same sectional area. The advent of these new bodies will be welcomed by all classes of road-users; for they not only do away with the trail of dust, but also with the clouds which frequently pour over the back.



Showing Dust Raised at Four Widely Different Speeds

Pierce-Arrow for 1910

In view of the consistent development of the six-cylinder type of car in the hands of the Pierce-Arrow engineers during the past three or four years, the announcement that the Pierce-Arrow Motor Car Company, Buffalo, N. Y., will devote its entire energies to the production of sixes during the 1910 season, will not come as a surprise. In all probability, it will follow the same policy from now on, but what will be decided on a year hence is a matter for the future. Three models are listed, the Pierce-Arrow 6-36, five passenger car, the 6-48 and the 6-66. As may naturally be assumed, all three are of uniform design and are characterized throughout by features of design and construction that are essentially Pierce, their differences being almost entirely those of dimensions. The four cars which made such a brilliant record in this year's A. A. A. Tour were the very first representatives of the new 1910 series to come through at the big plant in Buffalo, and they were only on the road in the hands of their drivers a week or two in advance of the start from Detroit.

There are probably not more than two or three other American automobile builders in the field who have so faithfully adhered to a basic design for such a number of years, so that it is naturally out of the question to look for any radical changes. Of improvements there are many, and all of a nature that strikingly demonstrate how closely opportunities are sought to better things here and there in the constant effort to attain the goal that so many builders are seeking—the perfect car. The performances of the cars in past years have convincingly shown that they represented such a close approach to this ideal from the mechanical point of view till little was left to be desired. But in the building of such a large number of cars, new points are constantly to be gleaned in the exacting school of experience, and as many of these, as have, during the past year, successfully withstood the searching test to which every innovation is subjected at the Pierce factory, have been adopted as standard features of the 1910 product. That the Pierce Company has based its

Six-Thirty Six Runabout for Three Baby of the Pierce Arrow Family

Six Cylinder Form and Three Horse-Powers

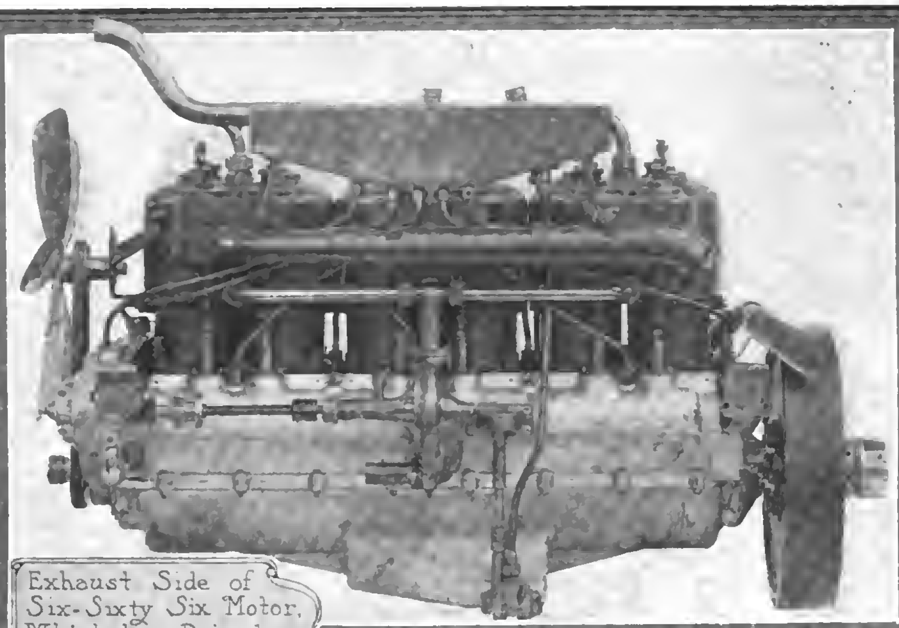
decision on a thorough knowledge of the situation where the six-cylinder car is concerned and has full confidence in the demand for this type, is quite evident from the fact that plans have been made to increase the output of Pierce-Arrow cars fully 50 per cent. over last year, when both fours and sixes were built.

As the three models listed for 1910 are practically identical in every respect, a description of one will suffice for all, and as all the essential features of the design have not undergone the slightest alteration, a resumé of the improvements will be of greater interest than a recital of the 1910 specifications.

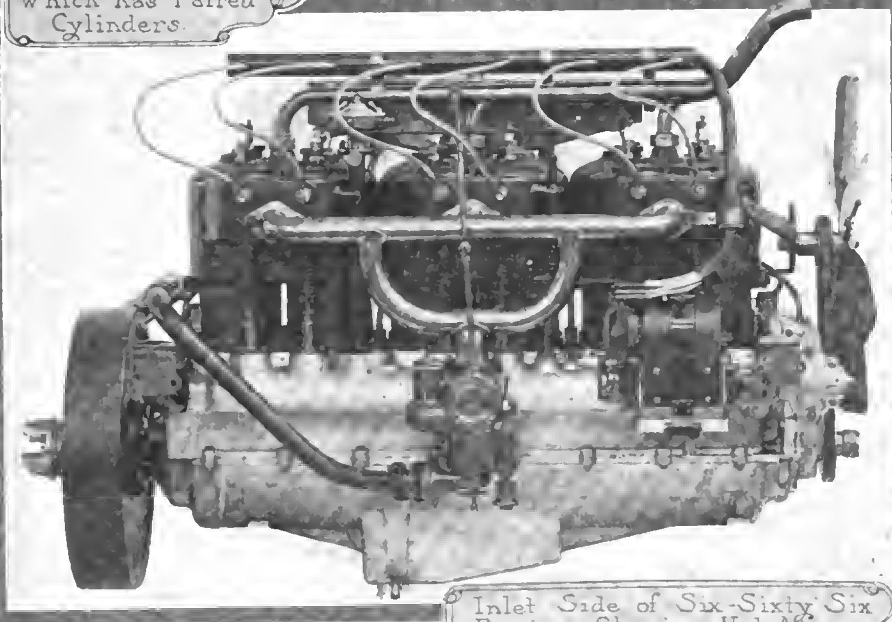
Aside from a slight increase in the dimensions of the cylinders, one of the chief changes in the Pierce motors has been the addition of an oil ring, or groove, at the lower end of the piston. The Pierce-Arrow circulating system of lubrication is so positive and forces such a quantity of oil to the bearings, that the baffle plates in the crank-case did not prevent an excess supply from reaching the piston and finding its way to the combustion chamber. Placing the oil ring in question on the pistons has added fully 50 per cent to the mileage obtainable on a single charge of lubricating oil.

The cylinder bore of the six-cylinder, 36-horsepower motor has been increased from 3 15-16 to 4 inches, while the motor dimensions of the 48-horsepower type remain the same as formerly. The motor of the 66-horsepower car has been practically redesigned since last year, the separately cast cylinders having been abandoned in favor of twin castings, making all motors uniform in this respect. The crank-shaft is still of the seven-bearing type, however, a liberal amount of bearing surface being specified for all the journals.

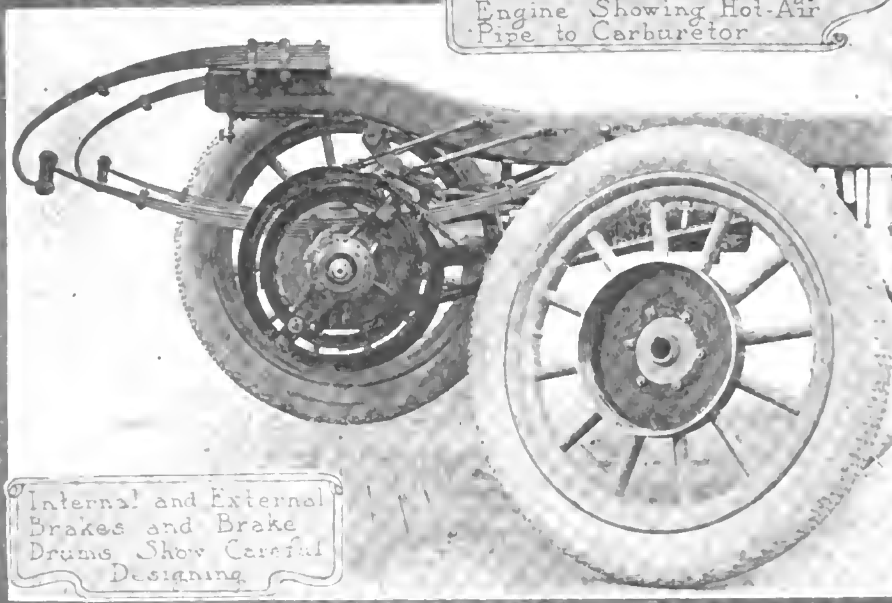
Specified on all models is the new type of carbureter—first adopted as standard last year, after a great deal of experimenting. It is of conventional design so far as the gasoline supply and spraying devices are concerned, but is fitted with a particularly ingenious type of auxiliary air valve, which is doubtless largely responsible for the extreme regularity of running



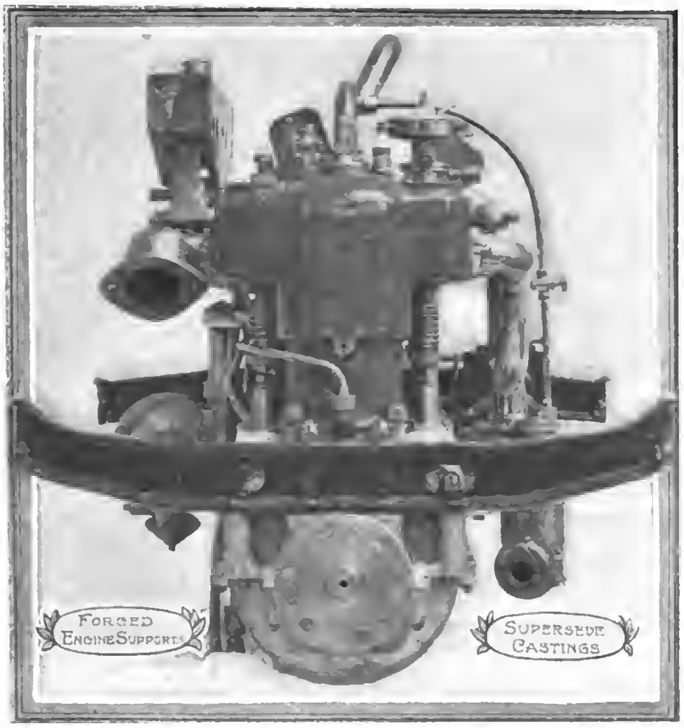
Exhaust Side of Six-Sixty Six Motor, Which has Paired Cylinders.



Inlet Side of Six-Sixty Six Engine Showing Hot-Air Pipe to Carburetor



Internal and External Brakes and Brake Drums Show Careful Designing



FORGED ENGINE SUPPORTS

SUPERSEDE CASTINGS

of the cars at all speeds. This air valve consists of a cylindrical chamber in the sides of which are placed vertical rectangular ports. These ports are covered by spring brass reeds, and are of varying dimensions, there being three in all. These reeds are in turn backed by flat leaf springs of varying tension, so that as the motor speeds to a point beyond the normal air supply, the first reed opens slightly until checked by the retarding influence of its spring: then more and more until fully open, when the next larger port begins to open, and so on until all are in action. This is very gradual and makes the carbureter extremely sensitive to changes of motor speed and load.

The Bosch magneto is retained as the service side of the dual system of ignition, a six unit set of plain Autocoils, synchronized by a master vibrator having been adopted for the emergency ignition system, in place of the six vibrator coils formerly employed. This greatly facilitates the adjustment of the battery ignition system, as but one vibrator has to be regulated. It is fed as usual, by a set of accumulators.

Doubtless the most important innovation in connection with the motor has been the adoption of the Spencer power air pump for inflating the tires. This is of a special design made for the Pierce-Arrow cars and is mounted vertically on the left hand side of the motor forward. It is bolted directly to a bracket on the side member of the frame and is arranged to be driven from the shaft that drives the water pump. A small bronze pinion is placed on the latter, and is intended to mesh with a gear of about two and a half times its size attached directly to the crankshaft of the twin cylinder pump. A ball and spring lock controls the position of the small movable pinion in the off and engaged positions, the latter being designed to be meshed by hand. The motor is stopped for that purpose and is then run slowly, not to exceed 300 to 600 r.p.m., at which it will suffice to inflate the largest tires to the maximum pressure required in a few minutes.

The remaining essentials of the motor remain unaltered, and as they are the same as have characterized Pierce construction ever since a multi-cylinder motor has been put out under this name, they are too well known to require description.

Some of the Transmission Improvements—The changes where this essential are concerned are simply those of slightly altered location. The housing of the gear set in each case has been raised slightly, 1-4 inch on the 36-horsepower car, and 3-8 inch on the other two models, and the shifting lever has been lengthened 2 inches on all models, to facilitate its handling. The arrangement of the foot brake and clutch levers has also been altered slightly, giving a great increase in the leverage and making it much easier to apply them. The gear-set is of the sliding type, selectively operated and gives four speeds forward and reverse, the shafts and gears being made from Krupp chrome nickel steel. The moving members are splined to their shaft, while the gears on the countershaft are bolted to flanges made integral with the shaft.

A change has been made from the Hess-Bright annular ball-bearings to Timken roller-bearings for the outer ends of the driving shafts of the live rear axle, in view of the ability of the roller type to withstand thrust stresses. This has also led to the exclusive use of Timken bearings for the front wheels, a change which entailed the use of entirely new steel stampings for the front hubs. Hess-Bright ball-bearings are used on all other moving parts, except the motor. Pressed steel has also been adopted for the brake drums and the dimensions have been increased in each case, in view of the slightly added power of the motors and the longer wheelbase of the cars, this increase in braking power averaging 25 per cent. Thicker Raybestos brake linings are also specified, and an improved arrangement of the brake hangers gives increased leverage with the same effort.

Chassis Changes Generally Are Few and Far Between—Wheelbases have been lengthened in every instance, the 36-horsepower car having been increased from 119 to 125 inches, while the 48-horsepower is now 134 1-2 inches, instead of 130, and the 66-horsepower model is 140 inches, instead of 135. The three-quarter elliptic springs first employed last year on the smaller cars have now been adopted as standard on all, and in order to preserve the height of the chassis at the same level, a dropped type of frame has been employed and the forward springs given slightly less arch. To compensate for the increased length of the car, the forward axle has been strengthened by giving it slightly heavier flanges.

The running boards have been made two inches wider throughout their length, and a sheet metal apron placed between them and the under side of the frame. This extends the entire length between the mudguards and completely encloses the sides of the car from front to rear. A new type of mudguard has been adopted, the forward ones being made with a straight slope to the rear, which facilitates the closing in of the sides. A 7-8 inch flange is now placed around all guards. A special housing is riveted to the forward end of the rear mudguard in order to encase the protruding end of the rear spring. Automatic grease cups are now provided on all spring shackle boats.

An additional lock has been placed on the ball thrust bearing supporting the steering column, and the latter has been given a slightly greater rake

New Shaped Lamp Uses Either Gas or Electricity

on the touring and enclosed cars, this being a 50 degree angle on the 36-horsepower car, and 49 degrees on the other two models. The hollow type of dash has been adopted for the 36-horsepower car making all three uniform in this respect, while the use of bright brass molding has been abandoned, aluminum covered with paint being employed instead. In addition to the slightly altered angle of the steering column, the control levers have also been arranged so as to be much more convenient. The steering wheels have been increased to a diameter of 18 inches.

Increases in Tire Equipment—Doubtless the most striking changes to be found on the new cars consist in the greatly increased size of the tire equipment to be provided on the 1910 models. Pierce-Arrow cars have always been noted for the liberal factor of safety afforded by their tire equipment, and the increases have been made in keeping with this policy. The 36-horsepower touring car, landaulet and brougham will be fitted with 36 by 4 and 4 1-2-inch tires, instead of 34-inch as last year, while the 48-horsepower cars will have 36 by 4 1-2 and 37 by 5-inch front and rear. Although larger diameter tires are employed for the rear wheels, all are interchangeable on the same rims, so that a rear tire may be used on a front wheel where desired, or vice versa, in case of emergency. This would not be recommended except in such cases, as it would impose an additional strain on the differential on the rear and would tend to render the steering difficult when used in front. The tire equipment of the 66-horsepower car consists of 37 by 5-inch front and 38 by 5 1-2-inch rear on the touring and enclosed types, the miniature tonneau and roadster being fitted with 37 by 5-inch tires all round, the equipment of these types of cars in the 36 and 48-horsepower models also being slightly smaller than those mentioned for the touring and enclosed cars.

The runabout and miniature touring types are built on special chassis in each case, the wheelbases being shorter and the bodies not being interchangeable on any of the other chassis. The brougham and landaulet bodies are interchangeable with the five-passenger touring type of the 36-horsepower model, this being listed as a strictly five-passenger car while the enclosed and touring bodies of the higher powered cars are interchangeable on either of the chassis, a 48-horsepower touring or landaulet body fitting a 66-horsepower chassis and vice versa.

Chief among the remaining changes to be mentioned are those of equipment. In place of the gas generator formerly supplied, a large sized Prest-O-Lite tank has been substituted, and a special box hung from the frame at the rear has been designed to accommodate it. This box is kept locked, and as a special supply cock is placed in the feed line just outside of it to turn the gas on or off, it does not have to be opened except to receive a new tank when the old one is empty.

In place of the gasoline gauge formerly placed on top of the gravity fuel tank under the forward seat, a special sight gauge glass is now mounted on the dash in plain sight of the driver, and a small electric lamp and push button are supplied to illuminate it at night. The gasoline feed pipe to the carbureter is also supplied with a union at each end, thus greatly facilitating its removal.

During the past year the Pierce art department has been at work on the designs of new fittings, and the result is to be seen in the new hexagonal lamps, door handles and the like. These designs are exclusive on the Pierce cars and the same motif will be employed throughout in the ornamentation.

Not only do these have a distinctive and different shape, but they are different, in that they are fitted to use either or both electricity and gas. The regular gas burner is located in the usual mid-position, while back of it, and slightly higher, is located the bulb of the electric lighting system. This is a small one of tungsten filament, and will give a light fully equal to that of the compressed gas.

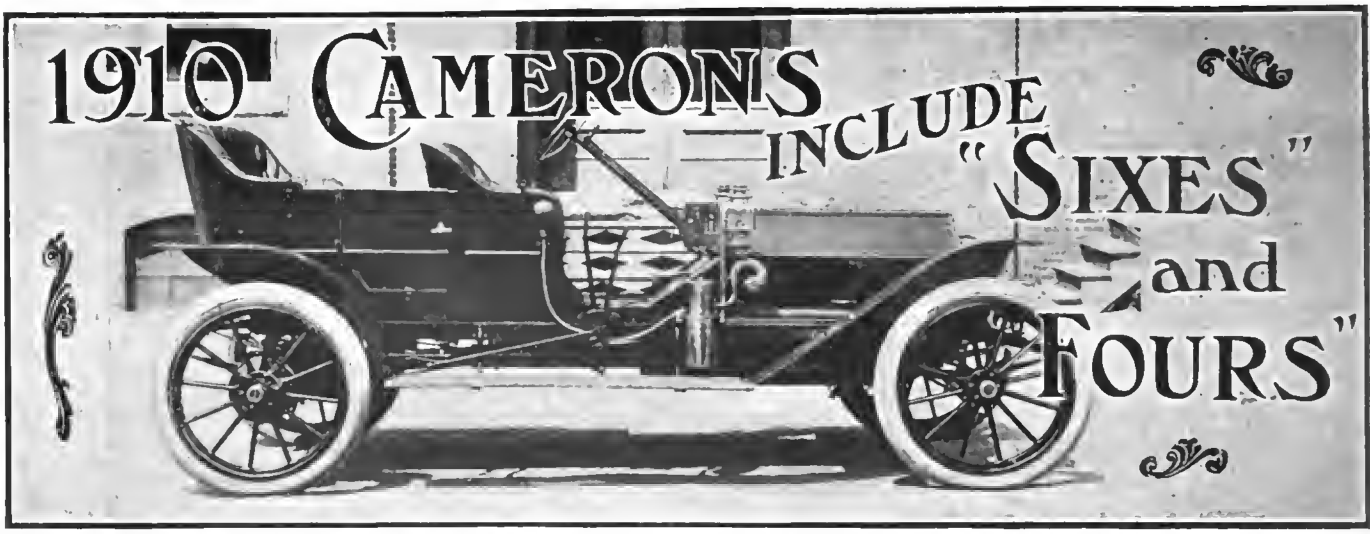
The lengthened wheelbases combined with the unusually large sized tires will make for increased easy riding, if that is possible on cars of the high grade of the Pierce-Arrow. The big six rear tires are probably as large as any now in use on a regular model. Several other cars have larger tires, but these are only sent ou on special order.

Something About Horsepower Ratings—In the following table it should be explained that the A. L. A. M. formula uses as a basis in computation a piston speed of 1,000 feet per minute. On this plan the number of revolutions of the 36 and 48-horsepower motors under the A. L. A. M. rating would be 1,262 revolutions and the 66-horsepower motor 1,090 revolutions. The nominal rating of the Pierce motors, according to various rating formulas, is about as follows:

	36	48	66
A. L. A. M.	38.40	48.6	66.20
Beaumont 750 Rev.	30.48	43.32	63.72
Beaumont 1000 Rev.	40.68	57.72	84.90
Royal Automobile Club	46.26	51.75	69.90

A general summary of the important motor dimensions, wheelbases and tire sizes of Pierce-Arrow cars is:

	36 H.P.	48 H.P.	66 H.P.
Motors	4 x 4 3-4	4 1-2 x 4 3-4	5 1-4 x 5 1-2
Wheelbases			
Runabout and miniature tonneau	119	128	133 1-2
All other styles	125	134 1-2	140
Tires			
Runabout and miniature tonneau	36 x 4	36 x 4 1-2	37 x 5
All other models, front	36 x 4	36 x 4 1-2	37 x 5
All other styles, rear	36 x 4 1-2	37 x 5	38 x 5 1-2



Six-Cylinder Touring Car Has a Long, Low, Rakish Appearance and Is Just as Fast as It Looks

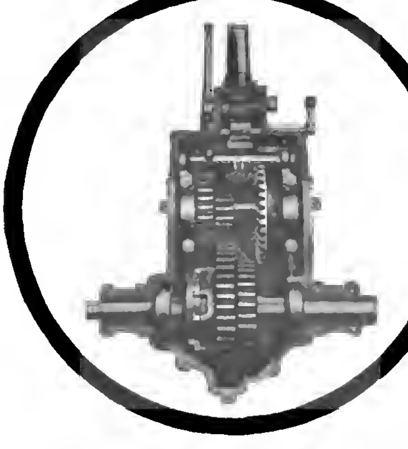
WEDDED as it is to the air-cooled engine and very light construction which goes with it, the Cameron Car Company, Beverly, Mass., and New London, Conn., will produce for the 1910 season both "Sixes" and "Fours," in a variety of runabout and touring car bodies, the former being preferred in the majority of cases. Not only will two separate and distinct types, such as a four and a six, be built, but they will be manufactured in two separate and distinct factories, each devoted to a single style and type of car. This should result in each one being superior to what it would be if the two were made under the same roof. The fours are manufactured at the Beverly plant and comprise five models, including two-passenger runabout, special two-passenger featherweight flyer, three-passenger roadster, four-passenger surrey with detachable rear seat, and standard touring car. The prices range from $950 to $1,100. The sixes are manufactured in the new plant of the Cameron Company located at New London, Conn., and the line comprises five models as above, all listing at $1,500.

It has been the policy of the Cameron Car Company from the very earliest days of its existence in 1902 to manufacture its cars complete in its own works, and this policy is being pursued in exactly the same manner to-day. The four and six-cylinder cars are manufactured in separate plants which build, from the ground up, all parts which go into their respective cars.

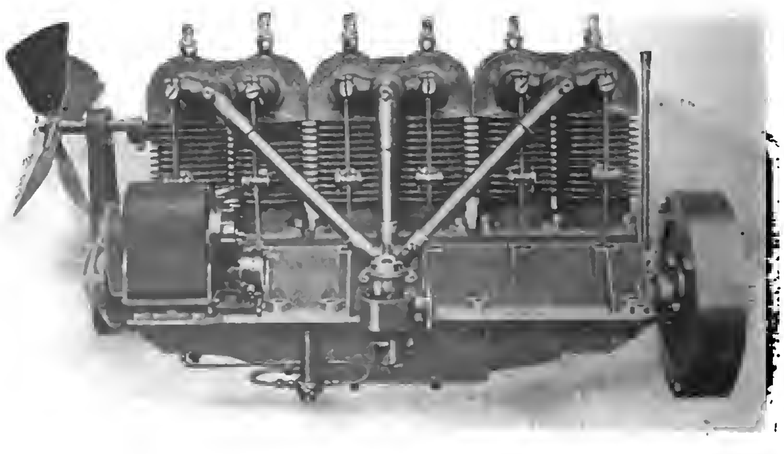
The motors for the coming season show no radical changes and are built along the lines on which Cameron has been working for the last seven years. Minor improvements will be found, but reference to the illustrations herewith will show that important features such as the system of air-cooling and location of valves remain the same as heretofore. The four-cylinder motor is 3 7-8 bore by 3 1-2 stroke, developing 24 horsepower, and the "Six" developing 36 horsepower. Both are regularly equipped with high tension dual system of ignition, which includes the magneto and auxiliary set of dry cells, gear pump, constant level oiling system of a very simple, effective design, oil being carried from a large chamber on the lower side of the engine base through a tell-tale on the dash and forced into the crankcase under a high pressure, where it is sprayed on shaft and connecting rod bearings. Thence it flows to the bottom of the case and lubrication is furnished to the cylinders by splash. The engine base is of aluminum, split horizontally in the center, the cylinders cast singly with radial fins.

Clutch is a self-contained cone of proportionately large diameter and easy angle of contact. Engine bearings are of nickel babbitt; camshaft bearings, case-hardened steel set in cast-iron bushing, and crankshaft rocker arms and all important small parts are of drop forged nickel steel. The wrist pin construction of these motors is the same as has been used by Cameron for years and is slightly different from that known to general practice, the wrist pins being steel drawn tubes, hardened and ground, with a hardened and ground connecting rod swinging directly upon them with no bushings whatever, thus giving two round surfaces as a bearing. These will run almost indefinitely without showing any signs of wear whatever. It is claimed that this construction will outlast half a dozen bronze bushings.

Transmission Rear Axle System—This is of the Cameron patented type, three speed selective, direct drive on all speeds. The six-cylinder system is slightly different from that used on the four-cylinder cars. This change will readily be understood by those who are familiar with the transmission. On the lighter



Six-Cylinder Transmission Is New



Inlet Side of Six-Cylinder Engine Shows Few Changes machines, that is, the four-cylinder line, the transmission carries three gears on the cross or jackshaft and one on the differential, while on the heavier transmission used in the six-cylinder cars, two gears are carried on the cross-shaft and two on the differential. While all of the six-cylinder models weigh less than 1,700 pounds, still this car is slightly heavier than previous models, and with the great power of the motor, of course, requires a heavier gear all round than the four-cylinder cars. The power is delivered from the engine to the rear wheels through a single universal joint to driving shaft and bevel gears, to the cross or jack-shaft, and finally, from the cross-shaft by wide face spur gears to the rear axle. The advantage gained in this construction aside from the fact that the gears, instead of being thrown into mesh sideways, are thrown directly together face on and rolled together with a natural motion, is the fact that the bevel gears never receive more than the engine pull, and being set up firmly in mesh in a solid steel frame running on adjustable ball bearings, have no chance of springing out of mesh under heavy load or showing any undue wear, which means loss of power to a bevel gear.

As the Four-Cylinder Touring Car Appears

In shifting gears, the arch carrying the gear set is first thrown forward in the case when the combination of gears wanted is thrown into line. When traveling crosswise in the case there is no strain against the gears to prevent sliding over. Gears are then brought together, face on, with a natural rolling motion which prevents jar, shock, or any injury to the gears themselves, as no strain of the engine pull can be put upon the driving gear until they are firmly in mesh and locked into position. The reverse gear stands idle except when in use, and is then thrown down in mesh from the top of the case. All gears are of unusually wide face and coarse pitch, are made up of drop forged blanks of chrome nickel steel, as are also the shafts. Ball bearings are used throughout the transmission and rear axle and are of annular type, of Cameron's own construction.

The application of drive to the chassis is the same as has always been used, that is, the drive is carried by a steel tube to a point directly back of the clutch. The distinct advantage claimed by this construction is that there is no tendency to lift on the chassis, but rather a straightforward push which holds the car steadily to the road even at extreme speed.

The rear axle itself is of the semi-floating type and equipped with internal expanding emergency brakes, also external contracting flexible bands on the wheel hub. The front axle is a seamless steel tube with drop forged ends and annular bearings used throughout the wheels. Frame is of pressed steel; springs are semi-elliptic front, full elliptic rear. Steering gear is composed of an adjustable enclosed rack and pinion.

Road clearance of all models is unusually good, and while much greater than cars of similar type, still the center of gravity is kept down to a point below that of many other cars of their class by reason of the method of carrying the transmission and the hanging of the motor in its sub-frame.

The weight distribution is excellent, the motors being hung well back of the front axle, and this, with the method of applying power to the chassis, gives the cars extreme stability.

More About the Speed—All models are very fast, it being claimed that while 75 per cent of the purchasers will remark that a car doing "twenty-five miles an hour is sufficient for anybody," that there is too much red blood in the veins of the average American citizen to sit back and let anyone throw dust in his eyes if he can help it.

This result is not sought after but is obtained incidentally to the light-weight construction, which, to use a roundabout way of figuring, comes from the use of the air-cooled motor of high efficiency. That is, the engine gives such a high ratio of power to weight, that combined with extremely light other parts, the *ensemble* is of unusual lightness. So much is this the case that this car may not participate in races sanctioned under the new racing rules. This is brought about by the fact that the new rules specify a minimum weight, and in framing them up, this lowest admissible figure was set so low as to go below the figure actually attained by Cameron. So, it is that, while actually "hankering" for a chance to race the cars against other and natural competitors, this company has been obliged to either abstain or go out of its class and meet much higher powered cars, with which it does not compete naturally. So, this competition would show nothing worth while. The Cameron Company uses this argument in favor of a revision of the existing rules under which racing is conducted.

The company has expanded greatly in the last year and states that for the 1910 season it will be the largest producers of air-cooled four and six-cylinder cars in the United States.

AVIATION'S UNUSUAL DEVELOPMENT

History has been made so rapidly in the new science of aviation that this staid old world is still rubbing its eyes in amazement, unable quite to comprehend what has happened. First Orville Wright dashed ten miles cross-country, over hills and ravines, carrying a passenger; one morning Louis Bleriot, with astonishing facility, flew across the English Channel; then the Rheims aviation tournament began, and since then miracle has followed miracle so swiftly that it has been difficult even to keep their record.

Last summer, when Orville Wright was making his first trials at Fort Myer, we declared our belief that the fundamental principles of aviation had been discovered, and that after perhaps a decade of experimenting and perfecting present designs it would be possible for the ordinary business man to buy an aeroplane and learn to operate it just as he now buys and operates an automobile. It seemed that the aeroplane was as susceptible of improvement as its forerunner on land, and that equal periods of time would bring equal development. Our prophecy was all too conservative. Not ten years, but a single twelve-month, has sufficed for that development. The progress which the automobile made between 1890 and 1900 the aeroplane has made between 1908 and 1909. Already there are half a dozen reputable firms in this country and abroad engaged in manufacturing aeroplanes as fast as their limited equipment allows, and their order-books are filled for months in advance. Prices range from $2,000 to $5,000. It is no longer thought necessary to guarantee flight; that is taken for granted.

No single feature of the Rheims meet has been so remarkable as the shortness of the training of many of the aviators, and the ease with which they learned to handle their machines. M. Bunau-Varilla, a youth of nineteen, received a Voisin aeroplane from his father as a birthday present; the other day he made a flight of 100 kilometers with the greatest ease. Rougier, a former automobile driver, scored in the height contest and incidentally flew 90 kilometers, with almost no preparation. Fournier purchased a Voisin machine, and after a few minutes' trial took up a friend as passenger and flew around the course. Ruchonnet, a foreman from the Antoinette factory, after some verbal instruction, made a good flight.

In spite of this comparative inexperience of the operators and the great number of machines present—it is estimated that 1,300 flights were made during the week—there was not a single fatal or even serious accident. It is a record of which any sport might be proud. Above all, the meet has conclusively demonstrated that the prospective aeroplanist needs no special talent, no long course of preparation; only a clear head and a steady hand.

THE PRESENT PRICE OF SPEED

Whether it be in the hazardous undertaking of "competing" in circular track racing, or in the more reprehensible practice of utilizing the public highway as a racecourse, it is plainly apparent these days that an alarming price is being paid for speed. Unfortunately, the spectacular performances of the few are magnified in the printing, with the result that the general public begins to ask if all automobilists are not more or less unseated in their reason when at the steering wheel. It is an unfortunate situation that has widespread advertising at the moment, with fatalities in and out of competition, and one cannot doubt but that the effect is decidedly injurious to the industry and pastime.

Many, harassed with natural timidity, are keeping off the roads because of the ever-expected appearance, round the turn in the road, of the man who deserves but seldom gets a jail penalty. In competition, the man who participates usually risks only his own life, though of late there has been, in several instances, inadequate means of safeguarding those who pay to watch a spectacle which not infrequently excels in blood-letting the sports of ancient Rome.

In most instances, it has become nothing more than a gate-receipts proposition, and the idea of betterment in the building of automobiles figures as of decidedly secondary importance. The manufacturers will do well to question the question of further support of mile circular track racing, while the automobile clubs can find a timely field of operations in ridding the road of its inconsiderate occupants.

Less of track sport and less of highway casualties are demanded for the good of automobiling; for the increasing list of killed and wounded is the worst kind of an advertisement, and one which is discouraging to the army of interested ones who have yet to become the possessors of motor-driven vehicles.

APPLICATION BLANKS OUT FOR ANNUAL A. M. C. M. A. SHOW

NEW YEAR'S Eve proved so fortunate an opening for the Grand Central Palace show in New York this year that Chairman R. E. Olds and his associates on the show committee of the American Motor Car Manufacturers' Association decided that they could choose no better date for the tenth show in 1910. The coming of the new year is always a gala occasion in New York, and automobilists and dealers like to combine the opening night of the show with the festivities which begin on Broadway at midnight. From the selling point of view, too, the date is a good one, as during the first week of the new year dividends amounting to $200,000,000 are disbursed by railroad and industrial corporations.

With the A. M. C. M. A. will also exhibit the members of the Importers' Automobile Salon, and the foreign cars will, as last year, be allotted space on the main floor. The Grand Central Palace show will thus be the only international show in America, and indeed, in the world, as it happens that there will be no Paris Salon this year.

Application blanks for space and diagrams of the floor arrangement have already been sent out to manufacturers who are expected to participate. This year the management has 72,000 square feet of floor space to dispose of, so that the exhibitors will be assured of better facilities than ever before. The main floor and part of the balcony floor will be devoted to American and foreign gasoline, steam and electric vehicles. Commercial vehicles and motorcycles will, as heretofore, be found on the balcony. The second balcony, with odd spaces elsewhere, will be given over to tire and accessory exhibits. The members of the Motor and Accessory Manufacturers have contracted collectively for several thousand square feet on the first balcony.

All applications for space received up to Friday, October 1, will have equal consideration in the first allotment on Friday, October 8. The allotment of space to the members of the Motor and Accessory Manufacturers will be made by that association, and the same plan will be followed for the members of the Importers' Automobile Salon. Members of the A. M. C. M. A. will have the first drawing for vehicle space other than that allotted to the Importers' Automobile Salon.

Associated with Chairman R. E. Olds, of the Reo Motor Car Company, on the show committee are S. H. Mora, Mora Motor Car Company; Benjamin Briscoe, Maxwell-Briscoe Motor Company, and H. O. Smith, Premier Motor Mfg. Company. The Importers' Automobile Salon will again be represented by E. R. Hollander, of the Fiat Automobile Company, and the Motor and Accessory Manufacturers will be cared for by David J. Post, of the Veeder Mfg. Company. The general management of the show will again be under the supervision of General Manager Alfred A. Reeves, of the A. M. C. M. A.

RULES FOR SAVANNAH-ATLANTA RUN

SAVANNAH, GA., Aug. 30—In connection with the widely extended movement for good roads in this State, and the large number of automobile contests planned for the opening of the Atlanta automobile show, there will be an endurance contest from this city to the scene of the exhibition in November. It will be held by the Savannah *Morning News* and the Atlanta *Constitution*, under the auspices of the Savannah Automobile Club, and will be known as the Georgia Highway Reliability contest. The start will be made from the De Soto Hotel, November 8, with a night stop at Milledgeville, and the finish will be at the Auditorium in Atlanta on the evening of November 9.

The rules as announced are much similar to those of the recent Glidden tour, embodying the principle ones with slight modifications necessitated by local conditions. The cars will have to be run on a definite schedule, with penalizations for lateness, will have to carry observers, and will be charged with time used in making repairs or certain adjustments. Three classes have been arranged, the first for cars catalogued at $2,000 and over, those selling above $1,200 but less than $2,000, and, third, those selling for less than $1,200. For each class there will be a cash prize of $335, with provision for a division of this sum among the drivers in case there should happen to be a tie.

1909 VANDERBILT CUP SEEMS ASSURED

NEW YORK, Aug. 30—Assurances that there will be a Vanderbilt Cup race this fall are now regarded as certainties. At Albany the Motor Cups Holding Company was incorporated today, "organized to promote automobile races for the silver cup donated by William K. Vanderbilt, Jr., and known as the Vanderbilt Cup, and for the gold cup donated by the Automobile Club of America, and known as the Grand Prize." The capital nominated is $5,000, and the incorporators include for the most part directors of the parkway. The names connected with it, at Albany, are: William K. Vanderbilt, Jr., Henry Sanderson, Colgate Hoyt, Harry Payne Whitney, Henry B. Anderson, Elbert H. Gary, William Pierson Hamilton, H. B. Hollins, Dave Hennen Morris and Mortimer L. Schiff.

The formation of this company is in line with the agreement reached by the A. A. A. and the A. C. A. last year by which the new company would promote the two great events over the Long Island motor parkway. Within the last few days the Manufacturers' Contest Association, composed of the automobile manufacturers, took a mail and telegraph vote as to what concerns would enter the Vanderbilt Cup contest, if it were organized and held this fall. It is reported that the results were surprisingly satisfactory.

FAIRMOUNT PARK RACE ENTRY LIST HALF FILLED

PHILADELPHIA, Aug. 30—Half of the number of cars which are permitted in the Fairmount Park 200-mile stock car race of the Quaker City Motor Club have been entered. Last week saw the number raised from six to ten, through the listing of two six-cylinder Thomas cars, a Benz and a Welch. All of these are Bergdoll interests, so that the young millionaire will have the greatest chance to win, if numbers count. The big Thomas cars will be driven repectively by Louis J. Bergdoll and Willie Haupt, the Benz by E. R. Bergdoll, and the Welch by Al Hall. Those entries made previously are: Acme, Leinan driving; Palmer & Singer, Walace; Simplex, J. F. Betz, 3d; Apperson, Herbert Lytle; Kline-Kar, and Lozier.

The charity feature of the event has attracted widespread attention, and many of the people most prominent in society, municipal and business circles will be found actively engaged when the end of the vacation season arrives. The University of Pennsylvania students have volunteered as ushers. The Globe Printing Company has donated all the printing of tickets for parking spaces and grand stand seats. If necessary, there are several local military organizations which may be called upon as guards, in addition to the 1,200 of the "finest" which the city authorities will have on the eight-mile course. Arrangements have been perfected for locating the repair and supply pits in front of the stands, thus giving the spectators a fine view of the quick action.

LOWERED FREIGHT CHARGES ON AUTOS

New York, Aug. 30—Through the efforts of the traffic department of the National Association of Automobile Manufacturers, a signal reduction in the freight rates on automobiles has been secured. Dealers, manufacturers, and the public, alike, will be interested in the announcement that, after October 1, the railroads will charge for shipments of single automobiles on an actual weight basis. Heretofore the rates have been made with a minimum of 8,000 pounds, for first-class freight, for all passenger machines with wheel bases exceeding 86 inches. As the majority of the popular-priced autos at present have longer wheel bases than this, there has been much complaint against a rating of 8,000 pounds for these light cars.

By the new arrangement there is claimed a more equitable distribution of the transportation charges, so that smaller machines will be taken at an equivalent of 5,000 pounds at first class. The charges will be increased only as the weight, size, and value increase. Similar changes will be made in the shipments of boxed or crated material, on which actual weight will apply, instead of the fixed medium. The new classification affects shipments originating in the Northern States east of the Mississippi river, thereby including practically the entire manufacturing belt. The Association's traffic department effected an arrangement on a similar basis with Western and Southern roads some time ago.

The entire automobile industry is represented in these matters by the N. A. A. M. traffic department, for it has an agreement with both the Association of Licensed Automobile Manufacturers and the American Motor Car Manufacturers' Association. J. S. Marvin is the general traffic manager, and the various automobile makers co-operate with him. To make the requirements of the industry known, Mr. Marvin attends the meetings of the railroad rate committees at various points, and thus keeps the automobile industry in close touch with transportation affairs.

TOLEDO'S AUTO INDUSTRY STILL GROWS

Toledo, O., Aug. 30—Through the organization of the Warner Gear Company this city gets another branch of the automobile industry, the third established here recently. The new concern has been formed by F. W. Warner, of Muncie, Ind., and arrangements have been made with the Overland Automobile Company to house it until a factory building can be erected. The machinery has been shipped and will be turning out gears as soon as possible. The Overland Company has given the new firm a contract for the manufacture of its gears and the new plant will be constructed on ground adjacent to the Overland factory. About 100 men will be employed at once and that gradually increased to the maximum of 500.

The third member of the trio, and the second established, is the Kinsey Manufacturing Company, which makes radiators, frames and sheet metal material. All three will be located on the same property, for the Overland interests have purchased five additional acres which will give space for several buildings. J. N. Willys, president of the Overland Motor Car Company, has stated that the force at the local factory will shortly be increased to 1,000, and that the greater part of the 1910 output will be produced in Toledo.

INDICATIONS OF INCREASING PROSPERITY

Indianapolis, Aug. 30—Messrs. Wheeler & Schebler advise that ground has been acquired in the rear of their present buildings, and contracts let for another addition to their plant. The new building will be of brick and reinforced concrete, three stories high, and will cover an area of 235 x 125 feet. This part of the plant will be devoted entirely to the assembling of Schebler carbureters, giving employment to 800 additional men. The entire plant is still running on a 24-hour schedule, the production of carbureters having reached 900 per day, and being expected to reach 1,000 per day within the next two weeks. Contracts have already been made to supply 220,000 Schebler carbureters for the 1910 season.

A MOST COMPLETE INSTRUCTION BOOK

To every owner of an automobile one of the most valued publications regarding the car is the instruction book issued by the factory. This is not simply because it may include hints for a novice, but because it has diagrams of the cars, and details of the construction. Especially is this true of one of the best instruction books issued this season, that of the Stevens-Duryea Company, of Chicopee Falls, Mass. The edition gives the details of the four-cylinder Stevens-Duryea cars so explicitly that one could be taken apart and assembled with no other guide. It is printed on heavy paper, and in as much style as would be given to the handsomest catalogue designed to sell machines.

Every part of the two models of Stevens-Duryea output with the four-cylinder chassis is listed, and its location indicated on photographs. The various assemblages, such as motor, transmission, rear construction, clutch, steering gear and axles are shown separately, and there are directions for the care and repair of them all. A most important part of the booklet is that dealing with the oiling systems, the various parts of the machine which need lubrication, and just how often they should be treated. Then there are detailed helps for finding any trouble or derangement, with directions as to the readjustment, being of special value in regard to the ignition and carburetion systems. By following the instructions given in the booklet there would be no need of hunting over an entire car to find the places for adjustment, for oiling and for taking up wear in the parts.

TEST RUNS BY THE WAVERLY ELECTRIC

Indianapolis, Aug. 30—Some interesting experiments were recently conducted by the Waverley Company to illustrate the different mileage that may be obtained by the same car under different road and service conditions. A Waverley coupe, equipped with a 30-cell, 11-plate battery, was sent with two passengers from this city to Noblesville and return, 51 miles, over ordinary country roads with several steep hills, and was then run about Indianapolis streets until the battery was exhausted. The total mileage was found to be 65.9 miles. The same car was used for the next test, but with a 30-cell, 15-plate battery substituted. Again the coupe was sent out, with two passengers, and running on the streets, rolled up a mileage of 90.1, which is regarded as exceptional. In the third test the car, this time with a 32-cell, 15-plate battery, ran to Terre Haute, 76 miles, and on Terre Haute streets until a mileage of 86 was attained. Then the same car was stripped to reduce weight, the coupe top being removed; with a 30-cell, 15-plate battery, and only the driver on board, it made 142 miles without recharging.

AMERICAN SAMPLE EXHIBIT AT BERLIN

Automobile and accessory manufacturers may be interested to know that arrangements have been perfected for opening a permanent sample exhibition in Berlin in the spring of 1910. The enterprise is in charge of the American Exhibition Company, 77 Broad street, New York, from whom blank applications for space and any desired information may be obtained. The aim of the exhibit is to demonstrate to European, and especially German, merchants and business houses the importance and excellence of American manufacturers, and to this end the German management will advertise the exhibition throughout the Continent, and will co-operate with American manufacturers and exporters in every way.

MOVING PICTURE SHOW "EN AUTO"

Columbus, O., Aug. 30—Albert Taylor, of Mt. Sterling, O., has devised a new use for the automobile, for since the wonderful growth of the moving picture business he has been carrying his entire outfit on an automobile truck. A machine with a capacity of three tons is used, and on this is loaded a tent and all the paraphernalia necessary.

How the Big New Atlanta Autodrome Will Look When Completed Ready for the November Races

AUTODROME WILL HAVE A $5,000 TROPHY

ATLANTA, GA., Aug. 30—The city of Atlanta is going to be asked to stand sponsor for the big $5,000 trophy that is to go to the winner of the star event of the races at the Autodrome in November. What is more, the people of Atlanta are going to be asked to take part in the presentation. This is all to be done at the request of the Atlanta Automobile Association. Not because the association wants any part of the expense borne by the people, but because it is believed that the citizens generally wish to take part in the donation.

It has been determined to give a $5,000 trophy to the driver coming in first in the big race, and on that trophy will most likely rest the seal of the city of Atlanta. It will be the gift of the city, and all the people will have an interest in the giving.

Mayor R. F. Maddox has named a committee to look after the trophy funds and to take charge of the matter for the city. The general council is expected to vote its approval of the gift.

CHEYENNE'S MOTORDROME A SUCCESS

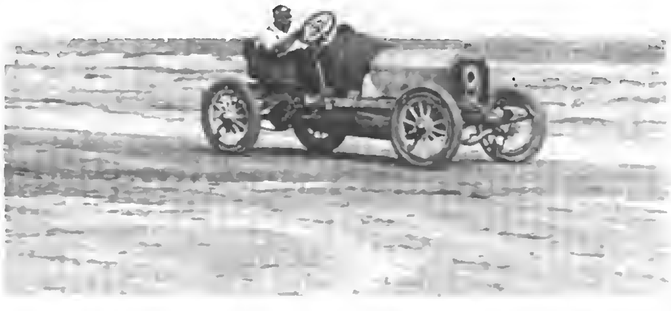
CHEYENNE, WYO., Aug. 27—The much-talked-of motordrome, built under the direction of the Cheyenne Motor Club, is considered to be a great success, and it will be much improved during the next few weeks. The great gathering in this city for the races, which were held here on August 17, has led local capitalists, as well as the members of the club, to enthuse over the prospects of making this the center for racing in the West. The Denver Motor Club was represented by a delegation of 200, who toured to this city in about 60 machines.

The two feature races last week were the one at 200 miles and the one at 25 miles, both well entered by a fast field. The long-distance event was captured by Martin Fletcher in a 40-horsepower Oldsmobile in 3:39:47, an average speed of about 58 miles per hour. The Marmon, driven by Harry Ball, was second, and the Renault, driven by Charles Basle was third. The other starters were: Moon, Harold Brinker; Colburn 30, Al Ingersoll; Colburn 40, Ernest Griffith; Buick, Gaston Morris. Basle, in the Renault, captured the 25-mile race, in 25:17, with the Oldsmobile second, in 25:59, and Ingersoll's Colburn third, in 27:36. Fletcher, in the Oldsmobile, was given official credit for the fastest four-mile lap, 3:40, or 65.4 miles per hour.

TEXANS RACE ON GALVESTON BEACH

GALVESTON, TEX., Aug. 28—A crowd of fifteen thousand people saw some fast racing on Denver Beach, near this city, last week. The five-mile course along the beach had been rolled hard and smooth by the waves, and many of the cars reached mile-a-minute speed. The popularity of the races came near proving their undoing, as the three policemen assigned were worse than useless to keep the course clear. After the first lap had been run the spectators swarmed out on the beach, and only opened a narrow passage as the speeding racers bore down on them.

The first event, a 50-mile free-for-all, was won by Belcher with a 50-horsepower Knox in 51:54 1-2, closely pursued by the 30-60 Stearns, driven by Kent. Captain J. W. Munn, who had entered a special car of his own construction, stripped a gear at the start. It is probable that even better time could have been made with a clear course. The motorcycles provided the fastest time, Hogans on an Indian covering 10 miles in 9:05 1-2. The last two races were run over a three-mile course. Dehyma, a young driver from San Antonio, won the second event with his Stoddard-Dayton in 22:05 1-2 for the 21 miles, in spite of the seven sharp turns. In the final, at nine miles, Dr. Gammon's E.M.F. beat a Buick in 11:40.



Knox, Which Won 50-Mile Free-for-All, Speeding on the Beach

Privately Owned Moon Cars in St. Louis Demonstration

"Made in St. Louis" was recently celebrated in that city. The line-up of Moon cars, two abreast, extended over two whole city blocks. This very large parade of locally made cars attracted an unusual amount of attention from the usually staid and quiet inhabitants of the Missouri city. This city has, however, despite the fact of its being staid and quiet, a very large number of machines in relation to its population, and what is more, the owners drive the cars themselves. The cars in the parade were mostly of the "45" type, since the new thirty is not yet being sent out for public use.

First Car from the Rider-Lewis Anderson Factory

Just 14 days after the installation of the new factory of the Rider-Lewis Motor Car Company, at Anderson, Ind., the first 1910 car was turned out. The capacity of the plant will be from 20 to 30 cars per day, and will soon be in full running order. The officers and employees of this hustling western company think that this is "going some" even for a hustling town. It is said that this same speed will be applied to the further production of the models for the ensuing year, which will be pleasing news to the many agents, who have already contracted for the factory output.

Seventy Feet Under Baltimore in a Winton Six Touring Car

W. L. Duck, manager of the Baltimore branch of the Winton Motor Carriage Company, recently took a party of friends for a ride in the new $1,500,000 sewer being constructed in that city. The tube is 5 3-4 miles long, its deepest section is 70 feet below the surface, the height 11 feet, and the width 12 1-4 feet.

MOON CARS ENTER THE $1,500 CLASS

St. Louis, Aug. 30—The popular $1,500 class has received another addition in the 1910 Moon "30," which the Moon Motor Car Company of this city will bring out as a running mate to its "45." The Moon engineers have been at work on the design of this car for the last two years, so that its production is undertaken with full preparation and forethought. In its general lines the "30" follows the usual Moon practice; many parts of the two models are interchangeable. The new car has not been skimped in any way to bring down the price. Its pressed steel frame is of a section 4 inches deep; it has 34-inch road wheels and a 1 3-4-inch crankshaft. A magneto is regular equipment. The change-gear gives three speeds, selectively operated, and is carried on the rear axle. About one thousand of these cars will be built during the coming year.

The Moon "45" for 1910 will be a continuation of the present model, with a few changes. The cylinder dimensions will henceforth be 4 3-4 x 5 inches; the wheelbase has been lengthened to 120 inches, and 36-inch wheels will be used.

Winton Prize Winner in Floral Parade

This car, owned and driven by Charles E. Bradfield, of Barnesville, O., won first prize in a floral parade held in that city recently. White roses were used chiefly in the decorations.

THE PIERCE WINNER'S TAIL LIGHT

New York, Aug. 30—In the showrooms of the Harrolds Motor Car Company, the New York agent for the Pierce-Arrow cars, is No. 108 Pierce roadster, which won the Hower trophy in the recent A. A. A. tour. There has been considerable contention since the finish of the contest as to the condition of the tail lamp of this car, and the Harrolds' officials are showing it to prove their claim that there has been a misunderstanding in the matter. It has been stated recently that this lamp was bent, that its bracket was in a similar condition, and that it is impossible to light it.

That this is a mistake, however, is shown by inspection of the protested part. The lamp and bracket are still covered with Kansas mud, and evidently no attempt has been made to repair it—if that had been necessary. The bracket is straight, as a comparison with those of touring cars on the show room floor shows. The lower half of the lamp—the part below the side lug—was evidently struck by something and bent slightly to the rear, but not loosened. The upper half of the lamp is as straight as it should be. The glass in the door was broken during the trip, but that the lamp would burn was proven by John S. Williams, who drove it in the tour, by the application of a match.

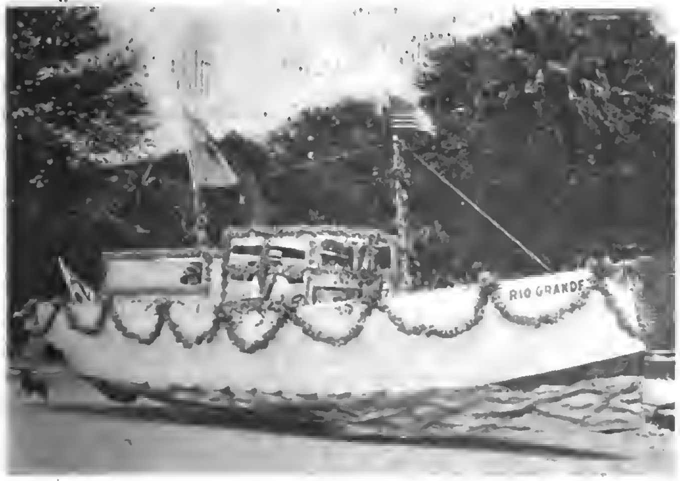
In regard to the statement that the Pierce-Arrow did not have to light its lamps all around in being tested, a Harrolds Company representative asks as to whether those cars which did light lamps were given their inspection at night. The lamps would thus be required by city regulations.

SUPERINTENDED BUILDING HER OWN CAR

When it came to building the car for Mrs. John G. Agar, of New Rochelle, N. Y., nothing else would do but that Mrs. Agar superintend the construction of the car, and, in particular, the body and trimming, herself. This was upon the occasion of the purchase of her annual car for the year 1909; that is, she has had so many Columbia cars, both gasoline and electric, that to the factory it seems as if she buys one every year. This latest acquisition is a distinctive car, in that it is one of the 50-horsepower Columbias, but three of these having been built by the Electric Vehicle Company, now the Columbia Motor Car Company. These three were powered with four-cylinder 5½ by 5½ engines, characterized by the usual make and break ignition and a number of new features not previously incorporated in Columbia cars. So well have these three cars done that the management is thinking seriously of adding this to the 1910 line as a high-powered leader. The Agar car, as shown above, was equipped with a five-passenger, close-coupled body, painted a dark blue with a stripe of lighter blue.

One of the Three 50-Horsepower Columbia Touring Cars

An unusual interest attaches to this car, for all of the final work upon it was superintended by a woman. It matters not that the chassis was all finished ready for the body when she took up her work, she should get the credit which belongs to her. The color scheme is an unusually beautiful one, also Mrs. Agar's idea, a very dark royal blue with a very fine hair line stripe of a lighter tint of blue. To the chassis, as well some interest attaches, since that, too, is out of the ordinary, being one of the only three fifty-horsepower Columbias ever built, these three being a special trial lot.



Decorated Premier Wins First Prize in Tampa Celebration

TAMPA TO HAVE AN AUTO RACE TRACK

TAMPA, FLA., Aug. 28—Among the several important instances incident to the phenomenal progress made by this city during the past eighteen months was the celebration of the Fourth of July. This took the form of a thanksgiving celebration in honor of the establishment of a regular weekly schedule by the Mallory Steamship Line between Tampa and New York City. The feature of this celebration was the automobile parade, in which over three hundred cars participated, all handsomely decorated. The procession made a tour of the city covering a little better than fifty miles of excellently brick-paved streets. The first prize was awarded to T. Edward Bryan, president of the Tampa Auto Club, and vice-president of the Tampa Board of Trade, who had his Premier "30" converted into an exact reproduction of the Mallory steamship *Rio Grande*, which was the first steamer to enter Tampa under the new schedule.

Within the past few days the Tampa Auto Club has purchased a tract of ',000 acres of land near the city, upon which it proposes to construct at once a five-mile auto race track.

Mrs. Kenneth R. Otis Gives Orphans an Outing

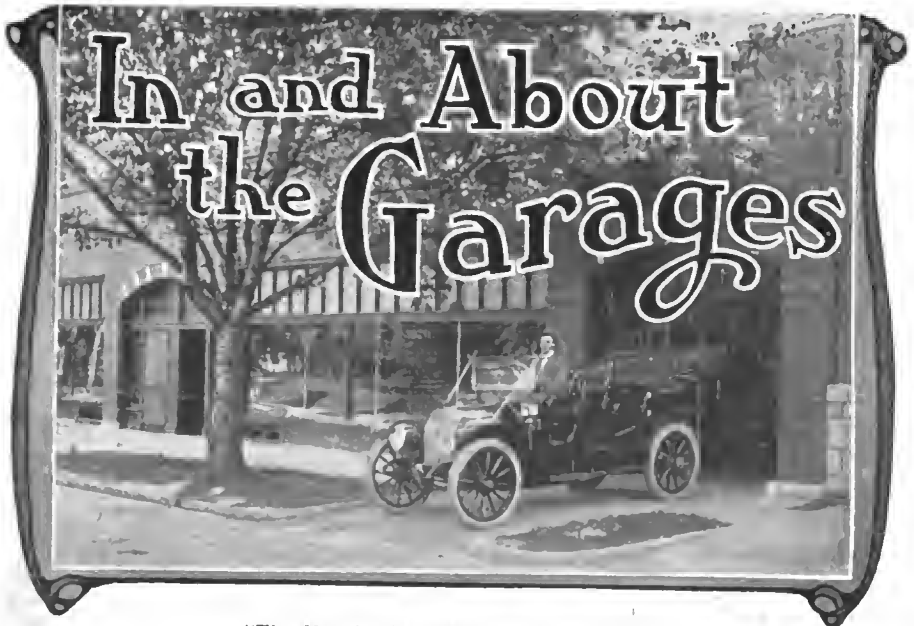
An impression that Mrs. K. R. Otis of Cleveland cares for nothing but breaking road records with her Stearns car is disproven by this photograph. It was taken during the recent Orphans' Day celebration in Cleveland, and shows Mrs. Otis seated in her car, surrounded by the orphan children whom she elected to show a good time on that particular day. Not only was the good time forthcoming, but Mrs. Otis, in the little ways peculiar to her sex, made the children riding in her car feel that they had an especially delightful day, more so than other children, who were so unfortunate as to be driven out for the day in cars handled by mere men. As usual, the car behaved perfectly, never once giving the skillful driver a chance to show how well she is acquainted with its mechanism nor an opportunity to display her skill in making impromptu roadside repairs. Mrs. Otis said that she enjoyed the day fully as much as any of the little charges in her care.

MAXIM VISITS OLD HOME IN A FRANKLIN

As illustrating the great strides made in invention in the later days is a trip made recently by Hudson Maxim, of gunnery fame, to his old home near Abbott, Maine. Forty years ago Mr. Maxim left his boyhood surroundings and made his way, as best he could over the rough paths, to the nearest town, and later to the big cities. His return, however, was under more auspicious circumstances, for he drove his six-cylinder Franklin touring car over Maine highways in as many hours as it had formerly taken days. In speaking of the trip, Mr. Maxim said: "The big Franklin took us from Indian Rest to Guilford in five hours' time."

Rushmore Lamps to Light the British King

This photograph shows the new English Daimler car with a Silent Knight engine which has just been purchased by King Edward VII of England. The car is equipped with Rushmore headlights, and is the second at the royal garage thus furnished. The picture was taken at the Goodwood races and the King is in the car.



"The Man in the Moon" is Henry Merrill

At the wheel of his Moon demonstrator, he is leaving the handsome garage of the Kansas City Moon Car Company, the Moon representative in Western Missouri, of which he is president.

HENRY, ILL., Aug. 30—The Henry Auto Company has recently completed one of the best equipped garages in this part of the State. It is a two-story brick building, with the basement acting really as the first floor. The main floor has its entrance direct from the street and is used by the salesroom, offices and garage departments. The lower floor is reached by an incline road on the exterior of the building, for automobiles, and is given over to the repair shop. The dimensions of the structure are 50 by 70, allowing ample space for the work of the concern. Inasmuch as it is situated upon the river bank, a considerable trade in motorboat supplies and repairing is carried on. A private heat and power plant is maintained, using electricity for power direct from the plant during the day, and from storage batteries at night, or when the dynamo is not being run. The shop is equipped with lathes, drill press, forge, emery grinder, air compressor and tank, and a full line of small and portable tools. The agency for the Ford, Rambler and Holsman automobiles is held, as well as for Ferro marine engines and Yale motorcycles.

UP-TO-DATE GARAGE—UP-TO-DATE CITY

KANSAS CITY, MO., Aug. 16—One of the handsomest show rooms and garages in the West is located at 3320 Main street, in this city. It is the local headquarters of the Moon Car Company, which is the exclusive agent for the Moon in Kansas City and vicinity. Henry Merrill, the president of the company, is the oldest dealer in Kansas City, and is the man at the wheel of the Moon demonstrator shown in the above photograph, which is just leaving the entrance of the garage. The company has had a very successful season and is making active preparations for the business of 1910.

Baltimore—A magnificent show room is being built by J. A. Rice, manager of Rice's Garage, Madison and North avenues. To make this improvement, 2,400 square feet of floor space which was formerly devoted to storage purposes, is being used. Manager Rice recently made an extended trip to the Welch factory in his six-cylinder Welch, covering almost 3,200 miles in the run.

Philadelphia—The Franklin Motor Car Company has given a contract for the construction of a machine shop and garage at 3430 Chestnut street. This will be made the headquarters and the present location at 143 North Broad street will be retained for show purposes.

Los Angeles, Cal.—Edward Gadden has had plans completed for the erection of a brick garage on Hope street, between Eleventh and Twelfth streets. It will be 50 by 157 feet in size, with cement floors, plate-glass front, reception and show rooms, shops, etc.

Jacksonville, Fla.—Frederick Philips has opened a new garage at the foot of Laura street, which is one of the best equipped in the State. He will hold the agencies of the Franklin, Chalmers-Detroit and Hudson. J. T. Mollard will be in charge.

New Haven, Conn.—The Wheeler & Wuesterfeldt Company has filed plans for the erection of a garage and automobile repair shop, to be built at Temple and George streets. It will cost about $21,000, and work will be commenced at once.

Valdosta, Ga.—Ground has been broken for a new garage and repair shop for A. A. Parish, at 116 and 118 West Central avenue. The buiding will be 60 by 90 feet in size and fully equipped with apparatus for storing and overhauling cars

St. Louis—The recently incorporated White Garage Company has leased the eastern half of the modern garage at 5023-25 Delmar Boulevard, and in addition to its garage business will have the agency for the White steamer.

Latrobe, Pa.—The Latrobe Automobile Company has opened a garage at Latrobe, 30 miles east of Pittsburg, on the main line of the Pennsylvania Railroad, and will have two good agencies.

Tampa, Fla.—The Southern Automobile Company has purchased the garage in the rear of the Almeria Hotel, and will conduct a general garage, repair and agency business.

Anderson, S. C.—J. S. Fowler has completed his new garage on West Benson street, and has opened it to the public. It is under the direction of J. C. Stribling.

Houston, Tex.—Lea, McKallip & Abbey have opened a new garage and salesroom at 714 Main street, and are acting as agents for the Jackson and Babcock cars.

Bolivar, N. Y.—A garage which will accommodate 30 machines will be built for Michael Healy on Belmont street. It will be 40 by 80 feet in size.

McPherson, Kan.—The McPherson Garage Company has occupied its new building on Main street. The building is of brick, one story, 50x120 feet.

Elizabeth, N. J.—Newton A. Barnett has opened the "Cranford" garage, with a capacity of 100 automobiles.

Henry Garage, with second floor down stairs.

A Squad of Ramblers Soon to Be Delivered Into Their Buyers' Hands

These cars were recently delivered to W. A. Nolan, of Grand Meadow, Minn., the Rambler agent for the vicinity, to be distributed among the prosperous Minnesotan wheat-growers. Automobiles are found on every farm in this part of the country.

Marmon Will Not Build Racing Cars—The Marmon car made its début in track racing at the Indianapolis meet, but the manufacturers state that they have never built racing cars, and have no intention of doing so. Three of the stock cars were put in the speedway events because the Marmon interests felt they should assist the home enterprise. The results, however, were exceedingly gratifying and cause for congratulation, because the machines again proved reliability, which has been shown many times on the road. One of the Marmons captured the 10-mile free-for-all, and another was third in the 15-mile handicap; but it was in the long-distance events that their best showing was made. In the 100-mile race there were two "Thirty-twos," and they took third and fourth places, making the century in 1:42:30—very nearly a mile a minute. In the 300-mile contest on the last day all three Marmons were running beautifully when the race was called off at the 225-mile distance. Only seven of the 19 entries were then left in the grind, three of them Marmons, and it appeared that they were sure of leading positions.

Additions to the Quaker City Auto Row—Before snow flies there will be at least two fine additions to Philadelphia's automobile district, one the building of the Dayton Motor Car Company at 253-259 North Broad street, and the other the new Horn & Hardart building at 242-248, just across the street. The Dayton Company's structure will be three stories high, 85 by 120 feet in dimensions, and thoroughly equipped from basement to roof with facilities for sales business, garage, repair shop, and patrons' and chauffeurs' club rooms. The main part of the Horn & Hardart edifice will be occupied by the local branch of the Winton Motor Carriage Company. It too will be three stories high, and its size will be 75 by 180 feet, of reinforced concrete. A recent addition to the row was the local branch of the Continental Caoutchouc Company, at 154 North Broad street, with S. S. Poor as manager.

Grout Showed Well in Hill Climb—At the recent hill climb of the Chicago Motor Club at Algonquin the 32.4-horsepower Grout was one of the class winners. The time of the cars in the formula class was taken in connection with the weight of the car and driver, with the piston displacement, and the result was a handy win for this car. Its percentage for its work upon the two hills combined was 8.03, with a leeway of 0.41 points between it and the second car, one of 8 more horsepower. Not only did it win through the combined formula, but the record on each hill was better than its competitors. In the plain time events it ran in a class with cars of greater power, finishing third.

New Buildings at Thomas Factory—Extensive building operations are now going on at the plant of the E. R. Thomas Motor Company in Buffalo. Factory No. 1 is being enlarged by the erection of a structure of saw-toothed type, 200 feet long, and plans are being made for building a separate factory, 280 feet long, 100 wide, and three floors high, in which to manufacture taxicabs. The latter will be erected only in case the concern is unable to secure for the work a suitable plant already built. Recently the officers of the company were treated to a trip down the river on a steamer and a clambake at Edgewater.

Rain Increases Texas Automobile Sales—A soaking rain during the latter part of the first week in August so increased the sales of automobiles in Dallas, Texas, that increased sales forces were made necessary. The assurance of heavy crops was brought by the water, and farmers immediately bought on futures. It has been stated on good foundation that 50 sales resulted from this reason alone. In spite of the great production planned by the factories, the dealers complain that they cannot secure deliveries fast enough.

Hoyt Electrical Company Expands—The Hoyt Electrical Instrument Works at Penacook, N. H., has purchased a piece of land on Main street with a frontage of 100 feet, on which to build a modern fireproof garage and salesroom. The increased business in electrical instruments has necessitated the entire use of the factory in this line. The new garage will be on a street which is part of the central trunk boulevard being built through to the White Mountains.

Grout Wins Two Prizes in Run—In the recent sociability run between Schenectady, N. Y., and Bennington, Vt., Mrs. C. T. A. Howe, of the former place, driving a powerful Grout touring car, won the prize for women drivers as well as the second prize in the competition. In the latter case her time was three hours and 46 minutes, and that scheduled was three hours and 51 minutes.

"Red Head" Now Copyrighted—The unique trade-mark adopted by the Emil Grossman Company, of New York, for its spark plugs has been copyrighted in the United States Patent Office, both the name and the design of the boy mascot, with his impish grin, being thus protected. The Emil Grossman Company says that 106 jobbers in this country are now handling the plug.

Columbus, O.—The Love Garage Company has recently been incorporated with a capital of $5,000 to operate a general garage business on West Fifth avenue. The incorporators are: Fred E. Love, James P. Love, R. E. Love, W. H. Furgeson, and H. J. Powell. The new concern takes over the business formerly conducted as a partnership by several of the incorporators.

New York to El Paso in an Auto—An interesting journey overland was started in New York last week, when C. A. Root left in his Packard car for El Paso, Tex. He stated that he hoped to travel 250 miles every day, if possible. The car is equipped with Continental tires, selected, according to Mr. Root, "because of their long wearing qualities."

Testing First 1910 Velie—H. G. Moore, secretary and sales agent of the Velie Motor Vehicle Company, Moline, Ill., is making a long trip to test the first of the 1910 product. Last week he reached Columbus, O., and ran to Cincinnati. The car is standing the hard run in fine shape, showing up well in tests of climbing and speed.

Great Western "in the Swim"—The Kansas City (Mo.) branch of the Model Automobile Company has evolved a picture postal showing a man fishing from the tonneau of a Great Western car, which is standing up to the hubs in a rushing stream. It is quite a clever bit of advertising, and should bring many inquiries to the hustling agent.

IN AND ABOUT THE AGENCIES

Selden, Philadelphia—The Selden car is the latest comer to Philadelphia's automobile row, having just been installed in handsomely fitted quarters at 336-338 North Broad street. The Selden Car Company of Pennsylvania, which is the official title of the new enterprise, has for its president L. S. Caswell, who has been identified with the Selden patent since 1897 and has occupied the position of sales manager at the Rochester factory. W. B. Alley is vice-president, and Fred. E. Dyer, treasurer.

Winton, Philadelphia—The Philadelphia branch of the Winton Motor Carriage Company will soon have a new home twice the size of its present headquarters. The building now occupied at 246-248 North Broad street is to be torn down and replaced by a more modern structure. Temporarily, Manager A. E. Maltby and his force will seek other quarters, but they will return when the new building is completed. It is expected to be ready for occupancy on January 1.

Morgan & Wright, Atlanta, Ga.—Morgan & Wright announce a change in the location of the Atlanta branch, having just taken possession of the premises at 50 North Pryor street. Herbert Starnes has succeeded the Alexander-Seewald Company as manager. Mr. Starnes is one of the oldest employees in the M. & W. service, and has acted as its southern representative in the States of Kentucky, Tennessee, Mississippi, and Alabama for several years.

Columbus Concern Enlarges—The Central Ohio Motor Car Company, which has the Columbus agency for the Velie and Hupmobile, has equipped a top and machine shop at its headquarters, 61 East Spring street. The plant is already in operation. C. Roy Clough is general manager.

Franklin, San Francisco—The new San Francisco branch of the Franklin Automobile Company has secured temporary quarters at 404-406 Golden Gate avenue, which it will occupy until January 1.

PERSONAL TRADE MENTION

Arthur T. Stewart, of Philadelphia, manager of the automobile wearing apparel department of MacDonald & Campbell, will sail this week for Europe. This is Mr. Stewart's annual trip to secure the newest styles from the foreign capitals. To bid him farewell, a dinner was tendered last Thursday evening in the Quaker City. Prominent automobilists and newspaper men were present at Turf Villa, on the banks of the Schuylkill, to give him a rousing send-off.

Paul L. Snutsel, foreign representative of C. F. Splitdorf, sailed on last Saturday for an extended trip to London, Paris, Turin, Barcelona, and Brussels. In each of these cities Splitdorf branches have been established to better care for a constantly increasing European trade in this company's magnetos and electrical specialties.

George T. Gould, who has been connected with the Rainier selling force in New York for the past year, has been appointed New England agent for the Rainier cars, with headquarters in Boston. He has already entered the field in that city, and has obtained show rooms and garage space on Boylston street.

H. N. Dunbar has been appointed manager of sales of the Mutual Motor Car Company, of Pittsburg, the agent in that city for Stearns cars. For the past year Mr. Dunbar has been in charge of the sales of the Gabriel Horn Manufacturing Company of Cleveland.

Harold A. Buzby, secretary and sales manager of the Keystone Lubricating Company, manufacturers of Keystone grease, is making a tour of the company's Western branches at Chicago, Denver and San Francisco. He will return about September 1.

Robert G. Pilkington, for 10 years a specialist in the design of commercial gasoline automobiles, has been placed in charge of that class of work for the Studebaker Company in Detroit.

Henry Goodman, who for the past five years has represented the Waverley Company in New England and New York State, has tendered his resignation, with future plans as yet undecided.

SWINEHART COMPANY ELECTION

Akron, O., Aug. 30—At a meeting of the stockholders of the Swinehart Clincher Tire & Rubber Company, the following officers were elected: President, J. A. Swinehart; vice-president and general manager, W. W. Wuchter; secretary, C. O. Baughman; treasurer, R. A. May. Mr. Swinehart will sail about October 1 for Europe to attend to the interests of the concern across the Atlantic, and in his absence, the active management will be in the hands of Mr. Wuchter. The latter for the past five years has been the general superintendent of the Firestone Tire & Rubber Company, and will now give his experience to the interests of the Swinehart Company. It is the intention to eventually embark in the manufacture of a pneumatic tire which is now being developed.

MODEL COMPANY NOW GREAT WESTERN

Peru, Ind., Aug. 30—A name which has been very familiar in this city during recent years will go out of existence on Wednesday. It is that of the Model Automobile Company, which will be changed to the Great Western Automobile Company, but with no alteration in the ownership or management. The new name, according to factory officials, indicates that the concern will continue its business along broader planes.

CHANGES IN THOMAS BRANCHES

Buffalo, N. Y., Aug. 30—The E. R. Thomas Motor Company, manufacturer of Thomas Flyers, has established a branch in Chicago, temporarily located at 1325 Michigan avenue until the new Thomas building is opened further up the Row. Cal T. Paxson, who has had charge of the Thomas retail department in this city, has been appointed manager of the new house, and has taken as his assistant Gaylord Warner of Kansas City.

Cal T. Paxson

Arthur W. Haile

Arthur W. Haile, formerly Mr. Paxson's assistant in the local sales work, has succeeded him as manager. Mr. Haile has had three years' experience in this line in Buffalo. The new branch in the Windy City is the third Thomas direct representation opened, the others being in New York and Boston.

CHANGES IN CONTINENTAL PERSONNEL

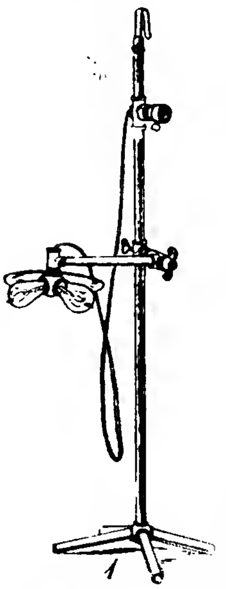
With the opening of several new branches and the appointment of sales manager well known in the trade, J. M. Gilbert, manager of the Continental Caoutchouc Company, has materially strengthened his selling organization. O. S. Tweedy, formerly manager of the Chicago branch of the Diamond Rubber Company, and recently connected with the Federal Rubber Company, has been appointed sales manager, with home offices at 1788-90 Broadway, New York. E. E. McMasters has been made the sales manager for the West, and J. H. Sheldon a similar position in the East. The new branches are located in Boston and Philadelphia, the first under the management of E. E. Kidder, located at 895 Boylston street. The Quaker City house is located at 154 North Broad street, under the direction of S. S. Poor.

A Prominent Car and Its Equally Prominent Producers and Sellers

Officers of the Chalmers-Detroit Motor Company and its latest product—the Chalmers-Detroit "Forty" for 1910. In the front seat at the wheel is H. E. Coffin, vice-president and designer, and beside him is Hugh Chalmers. In the tonneau are Messrs. Bezner, Brady, and Counselman; also Carl H. Page, the New York City dealer

Information for Auto Users

Aladen Portable Light Stand—Owners and chauffeurs who have ever tried to make adjustments by the light of a ceiling lamp, or who have had their hand lamps, after being carefully draped over the dashboard, suddenly fall on the cylinder head and suffer a smashed bulb, will appreciate this portable light stand brought out by the I. J. Smith Mfg. Co., 4283 Park avenue, New York City. The light itself consists of a cluster of four bulbs, backed by a reflector, and furnished with 15 feet of cable and an attachment plug to go in an ordinary electric lamp socket. The cluster is carried on a doubly jointed arm, similar to those often used in draughting rooms, so that it may be adjusted to throw its light in any direction. The arm in turn is carried by a 6-foot stand of steel tubing, with a broad base, and may be slid up and down and clamped at any desired height. The top of the stand is provided with a hook, by means of which it may be hung from the ceiling. Thus a steady and powerful light may be thrown on any part of the mechanism of the car from any desired direction. The cluster of lights may also be detached from the stand for use as a hand lamp.



ONE POSITION OF THE STAND.

The wire which connects the stand with the plug is held clear of the floor, so that it will not trip up any one working around the machine and will not be worn out. As a convenience this little stand is far more valuable than its size and cost would indicate.

Veeder "Odo" Has New Gear—The new model of the Veeder odometer, known as Form B, is equipped with a spiral driving gear, for which the Veeder Mfg. Co., of Hartford, Conn., claims many advantages. The gear has a much wider face than that formerly used, which gives a greater wearing surface and allows for end play; at the same time this makes close endwise adjustment unnecessary. Nevertheless, the gear has all the advantages of the old narrow gear, as it cuts easily through mud and dirt, and the spiral teeth eject any obstructions that may come between them. The gear is made of steel, with cut teeth, and despite the hardest kind of usage will last almost indefinitely. The bearings, too, are improved, and are much heavier than those of the 1909 model. The new gear is especially adapted for service on trucks and other heavy vehicles. The body of the odometer remains unchanged. The Veeder Mfg. Co. is now supplying the trade with this type of instrument at the same list price as last year's type of Form B.

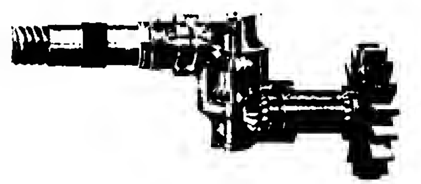
In this respect the Veeder company is following its usual policy of constant improvement.

"Guide" Electric Auto Lamps—Another believer in the future of electric automobile lighting is the Guide Motor Mfg. Co., of Cleveland. This company makes an extensive line of electric lamps and searchlights for automobile use, and also for motor boats. One of the special features found in "Guide" lamps is the dust-proof front, which prevents obscuring or tarnishing of the reflector. Tungsten bulbs are used in all lamps. To give some idea of the numerous styles in which these lights are made, it may be said that the "Guide" line includes three different types of headlights, three of side lamps, one of which is illustrated herewith; two tail lamps, a meter lamp and a dome light for closed cars, all made in several sizes; besides searchlights and side lights for boats. In addition to lamps, the company handles the Elba and Kremlo storage batteries, which, unlike the usual ignition battery, are built for high discharge rates and are thus adapted to lighting use, as well as the K-W magneto.

The many advantages of electric lights are becoming more and more generally recognized. They are clean, odorless and easily operated; they are perfectly reliable, not being affected by the wind nor liable to leakage or clogging; and they are, above all, safe for use around gasoline, as they have no naked flame. The only objection to them hitherto has been their expense, and this has now been obviated by improved bulbs and batteries, and, even more, by the use of mechanical generators.

THE "GUIDE" HEADLIGHT—DUST-PROOF AND EXTREMELY NEAT.

Stewart & Clark Swivel Joint—One of the features of the 1910 Stewart Multipolar Speedometer, made by the Stewart & Clark Company, of Chicago, will be a ball-bearing swivel joint, which eliminates the bends in the flexible drive shaft, permitting it to be carried back along the frame of the car direct to the speedometer. The X-ray view shown herewith reveals several interesting structural details. The joint, as will be seen, consists of two pairs of bevel gears, one gear of each pair being carried on a vertical spindle. This spindle forms the main axis, about which the sleeve carrying the end of the drive shaft can swing freely. The two horizontal shafts, connected with the drive pinion and the shaft, respectively, each run on two rows of balls. The two bevels on the vertical spindle are cut from one blank, and run on a long plain bearing. The whole construction is, of course, oil and dust-proof, assuring long life to the wearing parts. The joint as a whole is patented, and will be an exclusive feature of the Stewart & Clark product.



X-RAY VIEW OF STEWART SPEEDOMETER JOINT.

"Aplco" Electric System—The Apple Electric Company, of Dayton, O., has perfected an electric lighting system to be used in connection with its familiar ignition dynamo, which offers many points of interest. This machine is distinctly a dynamo, such as is used in large power stations; as its magnets are non-permanent, but excited by field coils, there is no danger of their weakening. The armature is multipolar, with 21 sections; the commutator has two combination gauze-graphite brushes set at 45 degrees from the vertical. The maximum output of the dynamo is 12 amperes. A storage battery of 30 ampere-hours' capacity, if used for ignition only, or of 60 to 100, if used for lighting as well, is connected to the dynamo through an automatic cut-out. The dynamo is provided with a governor and a load regulator, which makes possible a direct drive from a variable-speed automobile motor. The construction of the dynamo is very neat and workmanlike.

The Apple company also supplies the various accessories necessary for electric lighting, including the lamps themselves, plugs, switches and wiring. Gas and oil lamps may readily be converted to electric by means of special fittings. Preferable to this, however, is the use of lamps specially designed for electric work, and these dispense with the useless ventilators and so make a dust-tight construction.

The booklet published by the Apple company shows a number of ways of attaching the dynamo, some one of which will be found suitable for almost any car. One ingenious way is by silent chain from the hub of a gear-driven fan. The dynamo comes fitted with either a spur pinion, a sprocket or a conical leather friction pulley; any of these drives is satisfactory and any one of them may be had on order.

LOWELL TROPHY—318 MILES

HOW THEY FINISHED

Finish	Driver	Car	Time
1	Robertson	Simplex	5:52:01 2/5
2	Poole	Isotta	6:13:37 1/5
3	Parker	Fiat	6:22:21 3/5
4	Burman	Buick	6:25:44
5	Basle	Renault	6:36:47 2/5

LOWELL, MASS., Sept. 8—George Robertson to-day again made clear his right to the American speed championship by his hard-fought victory in the National Stock Car Championship. His Simplex car, the same one which had seen much service in 24-hour races, covered the 318 miles necessary to win the Lowell cup in 5 hours 52 minutes 1 2-5 seconds, at a speed which averaged 54.2 miles an hour. After many vicissitudes at the start, Robertson seemed to have a good lead at the two-thirds mark. Shortly after that point, however, Grant and his Alco began to creep up. Robertson secured a little more lead in the twenty-seventh round, but in the twenty-eighth ignition troubles fell heavily on him and he had to allow his rival to take the lead. Stopping at the pits, he changed spark plugs, consuming in all four minutes. And, then, when Grant had success almost in his grasp, he met with misfortune. One of his tires blew out on the hair-pin turn, and almost at the same time a driving chain broke. He was compelled to look on idly while Robertson dashed past into his former position, and while Poole, Parker, Burman and Basle took the remaining places. The two Knoxes, the American and the Lozier were still running when Referee Hower declared the race at an end. The many thousand spectators went home much pleased with the racing, but disappointed at not having seen the Presidential box occupied by one

Starter Wagner-President Speare

Officials Who Faithfully Performed Their Arduous Duties

McMurtry, Edwards, Beecroft

William Howard Taft. The President's absence was the sole disappointing feature of the day, and one which no one has been able to explain satisfactorily. Although he had not actually promised to attend, his well-known liking for the sport and the nearness of Beverly made the supposition lie strongly in that direction.

All Was Activity as the Big Cars Started

Sixteen cars assembled soon after nine o'clock in the official avenue between the grandstand and the press stand. The scenes for the hour following were infectiously animating in the crisp Autumn air, tempered by the rays of Old Sol showered from a cloudless sky. Gradually the enormous grandstand accumulated its load of humanity. The fair sex supplied artistic costumes in generous quantity, displaying all the colors of the rainbow, and a few never seen in nature. The music of the band chimed with the roaring exhausts of the impatient speed craft, which the energetic Wagner was arranging in two lines with the skill gained by long experience. President Heinze, of the Lowell Automobile Club, who has been active in all the preparations, looked on with an anxious eye, praying that the day would end without accident of any sort. Now and then he glanced in the direction from which the Chief Executive of the United States might appear, for the assurance had been fairly positive that President Taft would drive over in his car from the Summer capital at Beverly. The presidential box had been prepared, and its tenantless condition told a story of expectancy.

Bent upon their various duties, President L. R. Speare of the A. A. A. and Chairman F. B. Hower of the Contest Board circulated in the stretch, from which occasionally the clear-voiced Prunty made an announcement. Stevens, Wright, Webb, Broadwell and others of some degree in the affair were in evidence.

As the hour for the start approached there was great dismay in the Buick camp, for Strang, the winner of many previous contests, who had drawn number one, had not appeared. Ten o'clock came, and still no word or sight of the speedy Buick. So it was that the first to face Starter Wagner was Drach with the low-hung American, its number "2" standing out boldly on the big square hood. It leapt away at the word with a roar and a cloud of blue smoke, and Hughes, the plucky driver of the Allen-Kingston, brought his machine to the line. The others got the word at 30-second intervals; No. 4 Buick, Burman, No. 5 Alco, Grant; No. 6 Isotta, Poole; No. 7 Fiat, Parker; No. 8 Knox, Belcher; No. 10 Knox, Shaw; No. 11 Fiat, De Palma; No. 12 Simplex, Robertson; No. 14 Knox, Downey; No. 15 Stoddard-Dayton, Shaw; No. 16 Apperson, Lytle; No. 17 Buick, Chevrolet; No. 18 Lozier, Cobe, and No. 19 Renault, Basle.

Robertson of Vanderbilt Cup fame called forth the plaudits of the crowd, and Lytle, Chevrolet, Grant, Poole and De Palma were not strangers to the enthusiastic fans. Strang's failure to start caused much disappointment, as he won the races here last year when he was driving an Isotta. Racing Manager Pickens of the Buick team later received word that Strang, *en route* to the starting line, had come in violent contact with a telegraph pole and had bent his front axle. However, he succeeded in making repairs, and later appeared on the course. All the other entrants, except those who had previously been scratched, appeared and got away in good shape.

STORY OF THE LOWELL TROPHY RACE BY LAPS

First Lap—All cars survived the opening lap, with Buick, Burman, passing Allen-Kingston, Hughes, and Knox, Shaw, falling back two places. Buick, Chevrolet, made the fastest circuit, its time being 10:41, and by this performance moved up two places. Otherwise there were no changes.

Second Lap—Now the changes came thick and fast. Chevrolet had the best of it in time, which meant that he was in the lead, with Lytle only a second behind.

Third Lap—Robertson forged to the front during this round, his figures for the total being 32:14, with Burman next in 32:38. Chevrolet had gone to the bad, just finishing the lap with a broken frame. No. 3 Allen-Kingston stopped for tires.

Fourth Lap—Robertson retailed his lead, with Burman still in pursuit. Soon after the latter passed Strang unexpectedly appeared and passed the starting point, apparently having repaired his damaged car. He started with a 45-minute handicap.

Fifth Lap—Robertson and Lytle were the chief contenders, with the Simplex timed at 53:43 and the Apperson at 53:56. Burman was third in 54:34, with Grant less than a minute behind.

Sixth Lap—Fourteen seconds separated Robertson and Lytle on this round, with Grant third and Burman apparently in trouble.

Seventh Lap—Only eight seconds intervened between Robertson and Lytle, and the fight could not have been prettier. One second over a minute behind was Grant and the Alco.

Eighth Lap—Lytle got past Robertson and the Jack Rabbit had nine seconds advantage on the round. Grant remained in third place.

Ninth Lap—Just half a minute represented Lytle's lead over Robertson, with Grant still hugging third over a minute behind.

Tenth Lap—Tire troubles on the backstretch caused Lytle to lose his lead, and when he came around to the pits, he took on two spare shoes. Of course Robertson moved up, his margin becoming ten minutes less ten seconds. Grant could not help advancing a notch. The Simplex had averaged 58.8 miles an hour for the 106 miles traveled.

Eleventh Lap—This proved to be an unfortunate round, for two contenders joined the down-and-outers, Lytle's Apperson suffering from a broken camshaft and Shaw's Stoddard-Dayton from a damaged axle. Chevrolet's Buick and Belcher's Knox had already disappeared. Thus there were thirteen of the original seventeen still in the running.

Twelfth Lap—With Lytle out of the reckoning, Robertson increased his lead over Grant. Parker's Fiat was in third place less than a minute ahead of Poole's Isotta.

Thirteenth Lap—Robertson's speed now showed an average of 58.3 miles an hour, and he had over three minutes lead on Grant, who in turn led Poole by about five minutes. Parker had his troubles in this round, coasting to the pits with a fire aboard from an overflow of oil. This was extinguished with little damage, but he had lost his good position.

Fourteenth Lap—Robertson had added to his advantage until it totaled 4 minutes 35 seconds, with Grant six minutes ahead of De Palma, and Poole eight minutes behind the Fiat pilot.

Fifteenth Lap—Robertson lengthened the gap by nearly three minutes more. De Palma drew closer to Grant, and Poole installed himself comfortably in fourth place.

Sixteenth to Twentieth Laps—Robertson stopped for supplies all round at the conclusion of this lap. At this time, he had a lead of 9 minutes 52 seconds on Grant's Alco. Grant had lost ground until his lead over De Palma's Fiat was but ten seconds. Poole still held the fourth notch.

Twenty-first to Twenty-fifth Laps—In the twenty-first lap Robertson's margin was but 1 minute 1 second, and Grant had bettered his position materially. De Palma held fast to third, and Poole and Burman were fourth and fifth respectively. In the next lap, Grant hauled up on Robertson until he was only 55 seconds behind. Again in the twenty-third lap Grant climbed still further and cut off three more seconds of the lead, and in the next cut off five more. De Palma was 7 minutes 25 seconds behind Grant. At this point the Allen-Kingston hit a tree at the hair-pin turn and retired. Robertson completed his twenty-fifth lap in 4:46:37, increasing his lead on Grant to 55 seconds.

Twenty-sixth to Thirtieth Laps—In the twenty-sixth Grant continued to gain and in the twenty-seventh got past Robertson and opened up a lead of 3 minutes 25 seconds. With this he seemed to have the race well in hand, but at the hair-pin turn his chain broke and a tire came off. Robertson again took the lead, finishing his twenty-eighth lap in 5:24:48. The contest then slackened, for De Palma, now the runner-up, was 7 minutes 25 seconds behind the leader. The Isotta was half an hour behind. Beginning his last lap, Robertson could hardly have lost. At 3:58 he dashed past the grandstand the winner, in the time of 5:52:01 2-5. He had lapped the De Palma Fiat, which had just stopped at the pits to change spark-plugs and take on water. De Palma made his twenty-nine laps in 5:54:26, and seemed to have second place cinched, but on his last lap he was delayed and it cost him the place. Poole's Isotta broke into second in 6:13:37 1-5. Parker finished third and Burman and the Buick fourth. Basle and his Renault, a famous 24-hour race champion, could do no better than fifth. The times of Parker and the Fiat, Burman and the Buick, and Basle were 6:22:21 2-5, 6:25:44, and 6:36:47 2-5, respectively. Knox No. 10 was still running on its 28th lap when the contest was called off, and American No. 2, Knox No. 14, and Lozier No. 18 were on the 26th lap at the flag.

TABULAR STORY OF THE LOWELL TROPHY RACE

No.	Car	Driver	First Lap	Tenth Lap	Twentieth Lap	Finish

PROGRAM TO CONCLUDE CARNIVAL

Although the automobile races on Monday, Tuesday, and Wednesday form the most spectacular part of the week's events, they are not by any means the only ones on which the citizens of Lowell rely for the success of their carnival. There are other events which to many will be even more interesting than the spectacular contests of the racing automobiles. The devotees of motor boating will have their especial day on Thursday, September 9, when a race on the Merrimac River is scheduled. This is open to boats of 30 feet length and over, and the distance is 100 miles. The race will start at the pontoon bridge.

Friday, a number of motorcycle races will be conducted under the rules and auspices of the Federation of American Motorcyclists, on the automobile race circuit.

Matson Breaks In a Young and Promising Driver

LOWELL—THE CARNIVAL CITY

By John A. McKenna, Sec.-Treas. Lowell Automobile Club

The city of Lowell has no Revolutionary history, although it is situated in the historic old county of Middlesex. It occupies a territory set apart at various times from the towns of Chelmsford, Dracut, and Tewksbury. The vertebrae column of the "Spindle City" is the mile of brick cotton factories that line one bank of the Merrimac River. It really got its backbone before the rest of the body politic developed; and to-day, when a municipality of 100,000 people has grown about the mills, the cotton factories remain one of the sights of the city. Visitors who desire to inspect such mills as are in operation can do so by applying at the counting rooms for a guide. While certain of the secret processes of manufacture are guarded, corporation officials are always willing to admit strangers within their walls.

Persons interested in manufacturing will also find the Lowell Textile School well worthy of inspection, and members of the faculty will be glad to explain the several branches of cotton, woolen, and chemistry that are taught there. The institution stands upon a commanding location beside the Merrimac River, just beyond the Moody street bridge, and is but a short distance from the entrance to the boulevard. It was founded by the State, and receives annual grants from the State and the city, but has also received large gifts through private generosity. It ranks as the most complete textile school in the country.

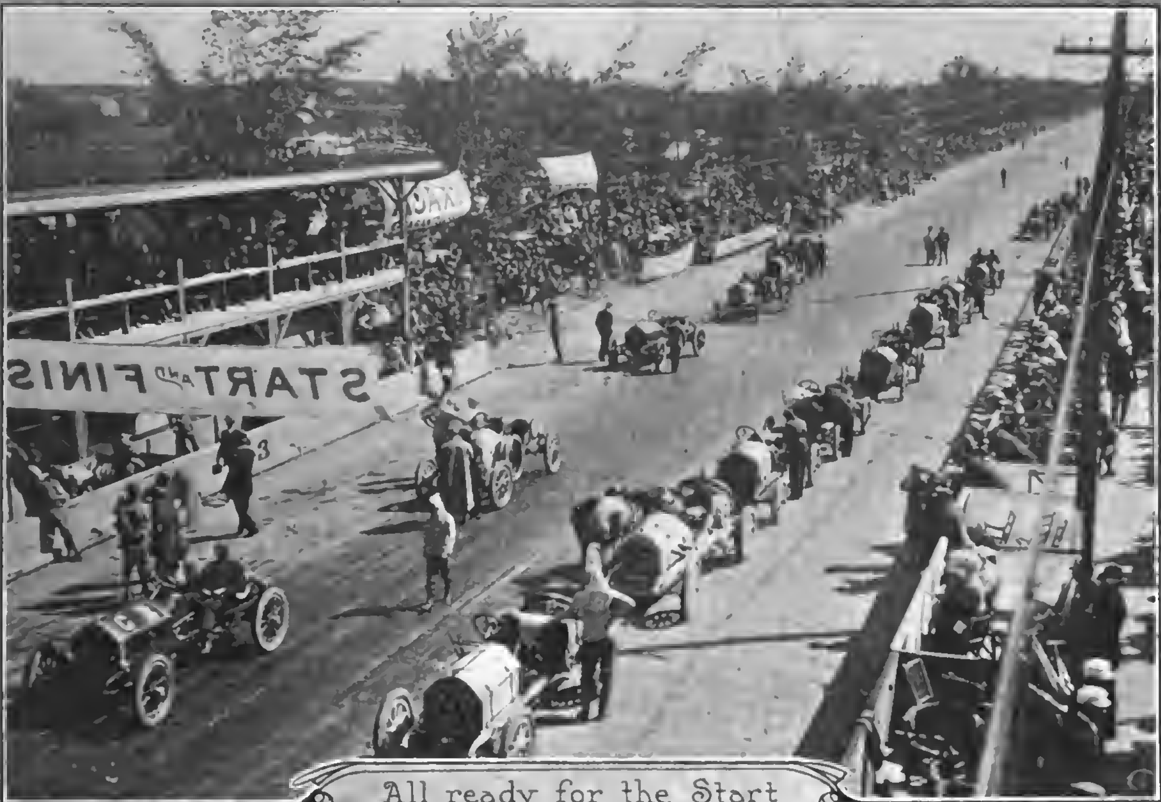
On Pawtucket street, three minutes' walk from the Pawtucket bridge, is the old Spaulding House, occupied as a clubhouse by the Daughters of the American Revolution, who have restored it upon its original lines. This was a tavern at the beginning of the last century, and is an excellent example of the architecture of that period. Another interesting old house that has been restored recently is the building in Worthen street, occupied by the Lowell Art Association. It was in this house that James McNeil Whistler, the artist, was born, and the clubhouse will eventually contain an art collection. The building is about two minutes' walk from City Hall and the Memorial Library, both handsome granite structures well worthy a passing inspection, and an equal distance from upper Market street, now the center of a flourishing Greek colony of 8000 people. Just back of Market street is the new Greek church.

The monument and statue that stand in City Hall Park mark the resting place of two members of the Sixth Massachusetts Infantry who lost their lives in the Baltimore riot, on the 19th of April, 1861. They and two comrades were the first volunteer soldiers to give their lives in the Civil War. In Lincoln square, reached by way of Chelmsford street, stands a monument dedicated this year to the memory of Abraham Lincoln, the gift of the school children of Lowell. It is a granite shaft with a bronze bas-relief by Bela L. Pratt, the Boston sculptor. The homestead of the late Major-General Benjamin F. Butler is a fine old building, partly Colonial, set in an attractive estate bordering on Andover street. The State Normal School, reached by taking a Broadway car, is an excellent example of modern educational buildings, and is surrounded by beautiful grounds. Pawtucket Falls, just below the entrance to the Boulevard, dams the Merrimac River in order to divert its waters into the canals that supply water power to the larger factories and machine shops. These canals are often visited by engineering students, so notable was their construction.

There are several Lowell clubs, three of them housed in substantial quarters. The Yorick Club occupies a large three-story brick clubhouse at Dutton and Moody streets. The Highland Club has a sightly building in the Highlands. The Vesper Country Club occupies the hundred acres of Tyng's Island, and has a handsome new clubhouse in addition to its rambling and picturesque old buildings that served the members for years.

Many inviting trolley trips are offered to the old Middlesex towns that lie in the circle just beyond the city, and there are two lake resorts that attract thousands of people weekly in the summer: Lakeview, a half hour's ride from the city, and Canobie Lake Park, an hour's ride away in southern New Hampshire.

HOW THE SMALL CARS CONTESTED FOR HONORS



All ready for the Start

LOWELL, MASS., Sept. 6—The automobile carnival opened to-day with the light car sweepstakes for Classes 2, 3, and 4, and Burman, Knipper, and Chevrolet, two on Buicks and one on a Chalmers-Detroit, each added another trophy to his collection. Magnificent weather was granted for the event, and the crowd began early to assume record-breaking proportions. So large and so enthusiastic was the assemblage, indeed, that the start of the race had to be delayed half an hour before a clear course could be secured.

Lorimer's Chalmers-Detroit came first to the line at 10:30, and dashed away at Starter Wagner's command. Shaw's Knox, Stoecker's Benz, Strang's Buick, Dingley's Chalmers-Detroit, Burman's Buick, Belcher's Knox, and Sharp's Sharp-Arrow followed at 30-second intervals. Coffey and his Columbia led Class 3, and Chevrolet's Buick, Knox's Atlas, Harroun's Buick, Davis' Moon, and Pepperday's Mercedes took up the pursuit at their given intervals. Of the smallest cars, Class 4, Grenon's Buick was first away, followed by Sickinger's Maxwell, Knipper's Chalmers-Detroit, DeWitt's Buick, See's and Costello's Maxwells, Matson's and Gelnaw's Chalmers-Detroits, and Disbrow's Buick.

In a few minutes the crowd in the grandstand rose to its feet to see the leading cars dash down the backstretch. Then the familiar cry of "Car coming!" arose. It was Lorimer, driving his Chalmers for all it was worth, as the time of 10:58 for the circuit attested. The Benz, Dingley's Chalmers, and then the Buicks of Burman and Strang dashed past in close order. Chevrolet and Coffey, of Class 3, had both passed the Sharp-Arrow, and gave promise of setting a speedy pace for the small cars. Shaw's Knox and Harroun's Buick both stopped at the grandstand supply pits, giving the crowd its first chance to see the well-drilled mechanics at work under pressure. Knipper's Chalmers led Class 4, with Grenon's Buick second. The Moon, too, stopped at its supply pit.

Lorimer held his lead well in the second round, completing the two circuits in 21:34. Dingley's Chalmers held fast to second place, and Strang's Buick came third. In Class 3 Chevrolet's Buick had jumped into third place in the dash past the grandstand, making it easily first in its class.

The third lap gave Lorimer an even greater lead, as he still continued his marvellous speed. Dingley followed his teammate, though at some distance; Stoecker's Benz was third, and Burman's Buick fourth. At the same time Chevrolet had rolled up a big lead in Class 3, his three rounds being completed in 33:18, only a minute and a second slower than Lorimer's. The Columbia struck a telegraph pole on the backstretch, but Coffey and his mechanician walked away unhurt. Lorimer made his fourth lap in 10:49, the fastest on record, and his time for the total distance was 43:08. Strang's Buick had jumped into second place, its time being 46:28. Stoecker's Benz and the Sharp-Arrow also had passed Dingley. In Class 3 Chevrolet was leading, followed by Harroun. Knipper and Matson had it all their own way in Class 4.

The same relative positions continued throughout the fifth lap, except that in Class 4 Costello's Maxwell replaced Matson's Chalmers as runner-up. Knipper stopped in front of the grandstand for water, providing a bit of unconscious comedy. Chalmers No. 47 took on a new tire. Word was received that the "C" Knox had run off the course at the lower turn and was badly damaged. Several persons were slightly injured. The "K" Knox had trouble and stopped for some time at the pit.

Lorimer's Chalmers finished its seventh lap, 74.2 miles, in 75:07 elapsed time, thus still further increasing its lead. Strang's Buick remained second. In Class 3 Chevrolet led Harroun by 11 minutes, and Knipper's Chalmers had a good four minutes over Costello's Maxwell in Class 4.

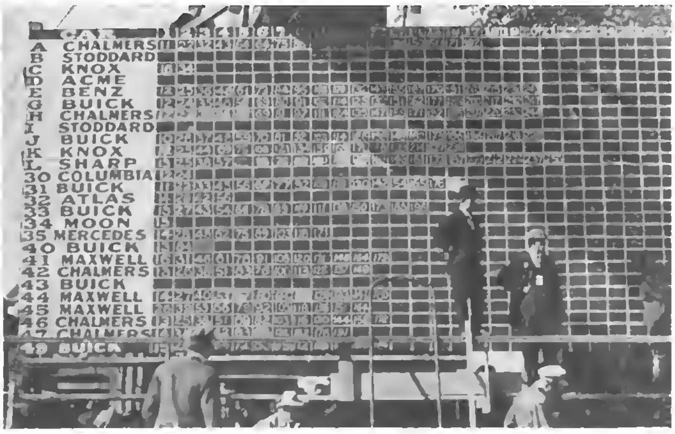
Chalmers Led at Half the Distance—When he completed his tenth round, half the race, Lorimer had nearly a lap on his

Burman Winning the Vesper Club Trophy in Class 2—Stoecker's Benz Which Finished Second Shown in Foreground Close to Fence

nearest competitor, the Strang Buick. Chevrolet lapped Harroun in Class 3. Lorimer gained still more in the eleventh, having nearly eight minutes on Strang and a little more on Burman. The Chalmers was running fine and averaging 60 miles an hour. Knipper's Chalmers made ten laps in 2:04:49, and with only two laps to go, seemed to have its class trophy won. At the end of the eleventh in Class 3, the Chevrolet and Harroun Buicks had things pretty much their own way. Davis drove his Moon off one of the turns of the backstretch, wrecking it, and the only remaining competitor was the Mercedes.

When Knipper next passed the grand stand he got the green flag for the last lap, having made eleven laps in 2:16:48. He finished in 2:28:43 for the 127.2 miles. Costello's Maxwell had a hard tussle with Disbrow's Buick, but the latter lost a wheel nearing the end of the last lap, letting Matson, too, slip ahead of him into third place. Costello's time was 2:44:01, Matson's 2:52:16, and Disbrow's 2:53:37. A protest was lodged to the effect that Knipper's car did not carry its hood for the entire distance, but Referee Hower subsequently ruled that this fault did not merit disqualification. Knipper drove a consistent race and well deserved his victory.

Chevrolet meanwhile was steadily reeling off laps in eleven and twelve minutes, and began his last round three laps to the



The Big Score Board That Told the Story of the Laps

good of Harroun. As nothing happened to disturb him, he took the race for the Yorick Club trophy, in the time of 2:56:17 for the 159 miles.

Burman Supplants Lorimer in Big Race—Lorimer's Chalmers kept on clipping off laps close to ten minutes until the eighteenth round. He was more than a lap ahead of Burman when at the end of the stretch, he lost control of his car, which skidded across a front lawn into a piazza on which were seated a dozen persons. No one was hurt, but the car was put out of the contest. Burman and Stoecker had a hot duel, which the former eventually won, crossing the line in 3:49:08. Stoecker stopped to change a tire, and that proved his undoing. His time was 4:02:55. Dingley and his Chalmers nosed out Strang for third place, after more fast work. It was an exciting finish, which kept the crowd constantly on its feet until the last car had crossed the line.

A GREAT DAY FOR THE LITTLE FELLOWS

Lowell, Mass., Sept. 6—Three races were fought out on the opening day in what seemed to the thousands of onlookers to be one contest. The victor in the field of eight, which made up class 2 for the biggest cars in the filed of 23 starters, was a Buick expertly handled by Robert Burman, who covered the 212 miles in 3 hrs. 49 min. 8 sec., averaging close to 56 miles an hour. Second ran a Benz driven by Stoecker from Germany, over a lap behind the winner, with a Chalmers-Detroit in charge of Dingley a close third. Not far in the rear came Strang and another Buick. In the Vesper Club trophy event, the cars had total piston area that ranged from 301 to 450 cubic inches.

Lorimer at one time apparently had the race won with a Chalmers which subsequently left the road on the 18th lap. By consistent and daring driving Lorimer had gained over a lap by the tenth circuit, his average being close to 60 miles an hour. His only stop was in the 17th round, when he took on gasoline and water, but neglected to obtain oil. This failure really brought with it the fatal consequences which killed the Chalmers' chances of winning. On the back stretch, when running at top speed, a piston seized owing to insufficient lubrication and not only broke the crankcase, but pushed the rear cylinders off. The cylinders fell into the steering gear in such a manner as to render the car uncontrollable and the car dashed into a nearby porch.

There came an epidemic of Buicks in the 231-300 class, Chevrolet running away with the Yorick Club trophy and having team-mate Harroun as the closest pursuer. A small Mercedes at the helm of which sat one Pepperday completed ten rounds, with the down-and-outers consisting of Moon, Columbia, and Atlas.

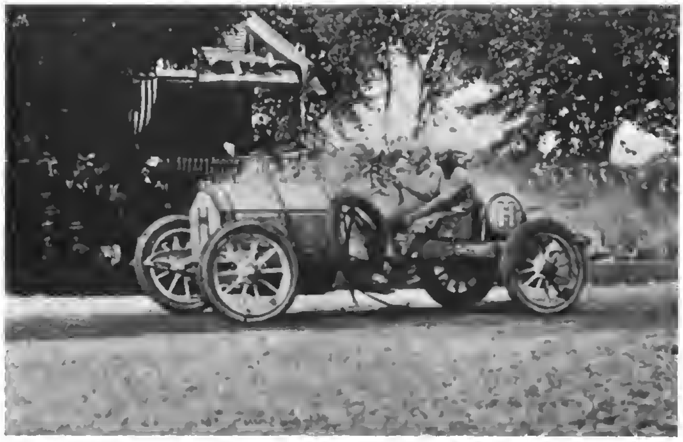
In the struggle of the littlest chaps—161-230 cubic inches—the Chalmers piloted by Knipper gained the Merrimac Valley trophy, though its loss of the bonnet for two laps caused a protest which gave Chairman Hower and his board associates a knotty point to decide. After a two-hour consideration this decision was announced:

The protest against the Chalmers-Detroit car, No. 42, for not carrying a hood at all times during the contest has been duly considered by the contest board and its decision is as follows: It seems that the hood fell from the car on the second lap on one of the curves of the back stretch, and that the car did not stop, but proceeded on its way. On the next lap the driver and mechanician made efforts to locate it, but failed. On the following lap it was discovered in a field, picked up by the driver and mechanician, and replaced on the car. The committee in investigating the case found that at the place where the hood was dropped it would have been dangerous for the car to have stopped within any reasonable distance. The committee also found that the hood was dragged away by boys. It was discovered by a nearby camper, who carried it to an open field near the road and placed it in plain sight. Taking all matters into consideration, the committee believes that the driver used all diligence in trying to locate the hood, and therefore the protest is not sustained.

Arthur See and a Maxwell made up the combination which figured as the runner-up, with another of the sturdy youngsters next, in charge of Costello. Joe Matson's Chalmers occupied fourth, with Sickinger's Maxwell and Grenon's Buick also among the finishers of the 127 miles.

While the enormous grand stand had some vacancies, due perhaps to New England thriftiness and endurance—one could get alongside the course for 25 cents and then stand or bring along your own camp-chair—there must have been close to a hundred thousand spectators scattered around the ten-mile circuit. While some minor catastrophies punctuated the racing nothing of a real serious nature happened. Shaw's Knox skidded at a turn, capsized a lunch stand, and turned turtle. In the mix-up several persons were more or less bruised. In the plunge from the road by Lorimer's Chalmers, one woman was knocked from a chair and, of course, badly scared. In other mishaps the results were small. The Columbia's swipe at a telephone pole put it out of commission, and DeWitt's Buick became a non-contestant at the same turn where the Knox came to grief.

To-day has been a day for the lower medium-priced machine in that the cars in the 161-230 piston displacement showed a better average performance than did those machines in the 231-300 class or the still bigger ones in the 301-450 category. The little fellows carried off the highest honors—nine of them started in their race and seven finished, the two to drop out being a couple of model 10 Buicks. The 301-450 class took second place in that eight of them started in their race and six finished, only a Chalmers Forty and Knox model R dropping out. The 231-300 cubic inch piston displacement class fared worst in that of the six starters only two were running at the finish, the other four, namely, Columbia, Atlas, Moon, and Mercedes having dropped out for one trouble or another.



Dingley in Chalmers-Detroit Who Landed Third

It must be remembered that the distances covered by these three classes differed very widely, the small class traveling but 127 miles, the second class 159 miles, and the big class 212 miles. Of the twenty-three that started fifteen finished and eight failed. Of the eight that fell by the wayside six went out directly because of breaking car parts and two were eliminated partly through breakages and partly due to an accident such as striking a bank or skidding into a ditch.

Here in a nut shell is the elimination list: Buick broke a rear wheel; Buick injured a rear axle; Columbia broke a steering knuckle; Moon had trouble with a stopped gasoline line; Mercedes broke a pump-driving shaft; Chalmers broke a crankcase; Atlas threw and had injured beyond repair on the road, two rear-wheel detachable rings; and Knox crushed a rear wheel when it struck the bank making the turn to the homestretch.

In the multiple-entry class, the three Maxwell Q specials carried off the palm in that all three finished, this being the only make of car with more than one entry in which all finished. Of the five Chalmers that started, four finished; five of the seven Buicks that started finished; and one of the two Knoxes. There were six individual entries, that is, six different makes of which only one car of each was entered. Of these six only two finished.

Start of the Winners of First and Second in Class 4 (Merrimac Valley Trophy)—Knipper's Chalmers and Sickinger's Maxwell

Matson Makes a Quick Change of Tires at Roadside

Knipper (Chalmers-Detroit) Merrimac Trophy Winner

namely, the Sharp Arrow and the Benz; Moon, Mercedes, Columbia and Atlas not completing their respective races. The entry list showed an unusually varied assortment of names. Many manufacturers who do not ordinarily take part in racing entered representative cars. Although this added greatly to the interest of the race, this elimination looks as though the newcomers had not made proper preparation.

There Were Few Stops at the Pits

There were only fourteen stops made in front of the grandstand repair pits in the three races. Belcher in Knox K was the heaviest grandstand loser, his two stops totalling 17 minutes, all due to ignition troubles. The first stop was for 6 minutes, when the coil was tested and a couple of new spark plugs used. This did not remedy the trouble, and on the following lap a 17-minute stop was made when it was discovered that a tooth or two on the magneto gear were stripped and a new gear was used and the motor retimed. A complete set of new spark plugs were put in on the magneto side.

Not a single one of the other contestants had to make two stops at the pits. Only one of the Maxwells stopped in the entire race, and that at the end of the second last lap, when No. 45 driven by Costello had to rope up the auxiliary gasoline tank on the side of the chassis, the brackets supporting it having broken. Two minutes and 24 seconds were lost. No. 47 Chalmers lost 2 minutes in taking on a couple of spare tires and adding water. "H" Chalmers lost 3 minutes taking on water, gasoline, oil, and tightening the clutch spring. No. 42, winner in the small race, stopped for water, adjusted the carbureter, and took on a spare tire, losing 1 minute. The only stop made by the Benz was 40 seconds to take on a spare tire. No. L Sharp Arrow lost 1 minute 10 seconds taking oil and strapping on an extra tire. Burman in "J" Buick lost 37 seconds taking on oil. Strang in "G" Buick required 1.5 minute for oil and taking on a right rear tire. Chevrolet lost 1 minute by having to take on oil, a spare tire, and jack. No. 33 Buick, in the same class and driven by Harroun, had a 2-minute stop to change spark plugs. No. 32 Atlas was but 50 seconds taking oil and water. Moon No. 34 lost 4 minutes adjusting the carbureter.

MECHANICAL DATA OF CARS IN MONDAY'S RACE.

41	**Maxwell Special**	Sickinger	Doorley	1,505	3.87	4.0	188.6
42	**Chalmers-Detroit**	Knipper	Schnoor	1,927	4.0	4.5	226.3
43	**Buick 10**	De Witt	Swizert	1,525	3.75	3.75	165.6
44	**Maxwell Special**	See	Wright	1,520	3.87	4.0	188.6
45	**Maxwell Special**	Costello	Conover	1,500	3.87	4.0	188.6
46	**Chalmers-Detroit**	Matson	Auder	1,960	4.0	4.5	226.3
47	**Chalmers-Detroit**	Gelnaw	Riker	1,975	4.0	4.5	226.3
49	**Buick 10**	Disbrow	Gerard	1,535	3.75	3.75	165.6

The scheme of allowing a couple of pit attendants to work in replacing tires or adding gasoline, water, and oil proved a good one, and the four men working on a car at once was an inspiring sight as compared with the tired driver and mechanic seen at road races in the past.

Where the Renault Team and Cars Were Housed

OLDFIELD EXCELLED IN MILE STRAIGHTAWAYS

LOWELL, Sept. 7—Mile-a-minute speeds were much in evidence to-day in the mile trials held this afternoon over the Pawtucket Boulevard. The start was near Dunbar avenue and the finish at the grandstand. The course record of 45 seconds, for a flying start, was broken by Barney Oldfield, driving the Benz Grand Prize car, as well as by "Herb" Lytle with the Apperson Jack Rabbit which will be No. 16 in to-morrow's long race for the Lowell trophy. Christie was an onlooker, his speed craft being hors du combat at the moment.

The big Benz made two trials. In the first, the time was 41 seconds flat, but in a second attempt this was bettered by traveling the distance in 39 9-10 seconds, an average speed of ninety miles an hour.

The straightaway course has a bend in it about half-a-mile from the start, which considerably reduced the speed of the high-powered machines. The surface, which was very oily, contributed somewhat more to the slower times made than anticipated. As it was impossible to make a flying start at high speed because of the tortuous approach to the starting line, few of the big cars could get up to their top-notch speed before reaching the start. At the finish, the cars had to be slowed down before the finish, otherwise the turn at the end of the boulevard could not be negotiated.

Considerable interest was removed from the day's program by the absence of Walter Christie and Lewis Strang. Christie's front-driven car was disabled early in the day by a broken shaft, while Strang's Earthquake did not run out of the shop.

Events 1 and 4 were scratched, as there were no entrants. Events 2 and 3 were walkovers for the Jackson and the Matheson respectively. The summary:

EVENT 2—$1,251 TO $2,000

Pos.	Car No.	Car	H.P.	Driver	Time

POINTS OF INTEREST ALONG THE COURSE

By LEWIS E. MacBRAYNE, Chairman Publicity Committee.

ALONG the Merrimac Valley course, over which the racing cars speed to-day in contests of national interest, the Indian once pitched his tent to fish for salmon, and the pioneer planted his corn on the plantations that had just been cleared. But this was long ago. The course offers points of interest to those who are historically inclined. The old road that leads across the boulevard to the pontoon bridge once connected with a ferry that plied across the Merrimac before any bridge was built, and between the boulevard and the backstretch there still stands the old Durkee house, which was a tavern in Revolutionary times. Many a stage coach from New Hampshire bound for Boston, in the good old days, has pulled up at this quaint hostelry, which was famous for its dinners in those days.

Continuing up the river, the boulevard runs parallel with Tyng's Island, now the property of the Vesper Country Club. Here the old chief of the tribe of Indians that had lived in the valley, Wannalancit, spent his remaining days after his people became scattered in 1665; and across the river just above the island may be seen the old Drake mansion, stoutly defended by Colonel Jonathan Tyng during King Philip's War, when every other settler had been driven back to the vicinity of Boston. The colonel was a son of Major General Edward Tyng, whose descendants all became noted Indian fighters.

Passing by the "Hairpin turn," and on over the hill at the beginning of the backstretch of the course, you will come to an old red house that stands corner to the road, across from the brook. It was built by Solomon Gilson in 1783 and is still owned by one of his descendants. Two houses below on the east side of the road stands the William Sherburne house, built by one Blood in 1780. It is recorded that "he was a victim of the 'Merino fever' and had it bad. He was said to be the only man who made any money at the time, but it developed later that he did not get his profit from his sheep, for after he moved away an outfit for making counterfeit silver dollars was discovered."

Going on again, a small frame house will be noted between the road and the boulevard. It was built more than 150 years ago, and its near neighbor, the old D. P. Coburn house, has stood for more than a century. The little red house opposite the Tyng's Island road, now owned by D. L. Page, of Lowell, was built on the race course at Mud Pond, and was moved bodily over to its present location by Nathaniel Coburn in 1775.

The Haskell Butterfield house, now used for a Summer School of Languages, was built about 1750, while the Butterfield house just beyond dates from 1790. Between the years 1725 and 1775 this quiet country road was the most populous part of Tyngsboro, and many a scene of social festivity occurred in these and many other old mansions long since destroyed.

On the part of the course on the backstretch within Lowell is a portion of fine old county road still lined by many of the trees planted in the days of the Revolution, while upon either side will be found the homesteads reared in the days when farms were several miles in extent, and the northern boundaries were described in the deeds as "the wilderness."

THE COURSE AS SEEN FROM A RACING CAR

LOWELL, MASS., Sept. 5—Accepting the invitation of the Chalmers-Detroit race manager, Harry Bill, a representative of THE AUTOMOBILE was taken over the course in Lorimer's "Blue Bird." This began at about six o'clock Friday morning, when at the judges' stand the writer took the mechanician's seat and prepared for what he expected would be a lively ride. For protection against the biting wind and stones, the scribe was togged with racing hood and rubber coat.

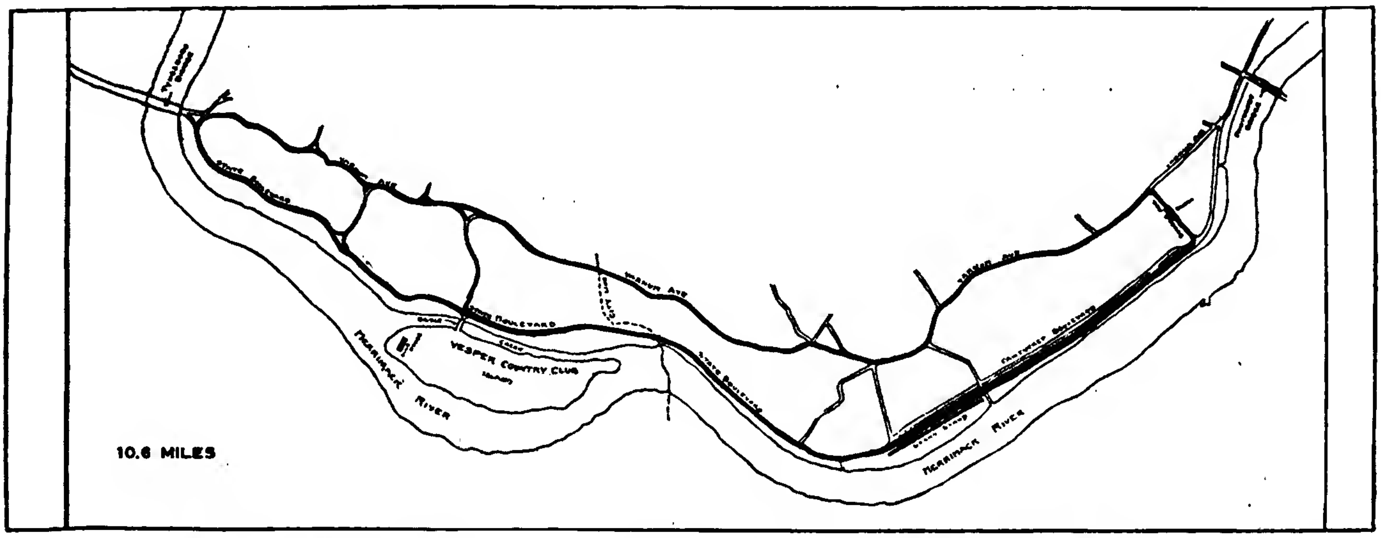
From the grandstand to the hairpin turn the road is macadam and thoroughly oiled. To dry up the oil, fine gravel was put on the road, which made it very uncomfortable for the contestants at high speeds, as the small stones were hurtled with the force of bullets almost directly into the faces of the crews. Unless radiators are protected by screens, there is danger of injury by flying stones actuated by passing cars.

From the start to the hairpin turn, about four and a half miles, there are fourteen turns, including one of the "S" variety. With the light Chalmers and skillful driving, Lorimer was able to negotiate these at nearly full speed. Although we skidded considerably, it was not so much but that a good driver could take care of his car perfectly.

Up to the hairpin turn, the road is perfectly level, and we easily held a seventy-mile-an-hour gait despite the curves. Not so on the backstretch, which contains thirty-five sharp turns and also includes five difficult "S" combinations. The so-called "Dip of Death" is also on this stretch. So difficult, in fact, is the back part of the course that it takes a speedy car and skillful driver to average much better than fifty miles per hour.

Just after leaving the hairpin turn, and before one can gain headway again, a long, sharp hill is encountered which necessitates a lower gear on many of the cars. The "Blue Bird," however, mounted this hill at a forty-mile pace on high gear. From the top of the hill until Dunbar avenue at the eastern extremity of the course is reached, the road is very tortuous and hilly. The "Dip" occurs about half the distance from the hairpin to Dunbar avenue turn and is a precipitous drop of thirty-seven feet in about a hundred yards. The sensation when going down this on a racing car is that of a descent in an express elevator in a skyscraper, or perhaps an emphasized roller-coaster. Altogether, the descent would not have any terrors if it were not for a turn at the fort and a quick ascent, beyond, which requires that the turn be taken wide open.

When we went over the course in our early morning practice, the car often skidded diagonally across the road, so viciously did Lorimer attack the turns. The last mile and a half of the backstretch are macadam, but the electric car track runs up the center of the road, calling for care when cutting across the road to take the turns. The turn from Varnum avenue, which forms the backstretch, into Dunbar, which connects Varnum with the Boulevard, is rectangular. The other end of Dunbar avenue at the Boulevard also offers a right-angle turn. These two turns were taken very fast, as the Chalmers can be skidded into the other



Map of Course Shows Location of Curves on Backstretch and Fine Straightaway Leading Past Grandstand road by appropriate braking. Lorimer drove the car at high speed until very close to the turn, then applied the brakes quickly, and the car seemed to take its direction as we slowed down. When in the turn we were facing down Dunbar avenue an application of power stopped the skid. This action was repeated at the other turn. From Dunbar avenue down to the grandstand, the Boulevard is wide and permits of as high speed as can be made. We did about seventy-five miles an hour, and for the first time on the run one realized the speed at which these cars can travel. One had to gasp for breath and the car seemed to be striving to push the back of the seat against you.

For the lap our time was clocked by one of the newspapermen as twelve minutes. This was equivalent to about eleven and a half, where a flying start and finisb can be made.

SOME GOSSIP OF THE MEET AND THOSE INVOLVED

Michelinites Had an Attractive Garb—In contrast to the nondescript dressing in most of the pits, was the serviceable half-uniform worn by the providers of Michelin tires. Khaki suits and blue shirts, with a dash of yellow in cap bands, made a neat combination.

Prunty's Far-Reaching Voice—Adding much to the enjoyment of the grand stand occupants, as well as a source of appreciation by the press, were the clearly-enunciated announcements of the silver-tongued Peter Prunty, imported from the metropolis for the occasion.

Technicists of National Repute—In David Beecroft and F. E. Edwards, of the Chicago Motor Club, and A. L. McMustry, of the Automobile Club of America, there existed a competent trio of technicists who, in the car examinations, conscientiously applied the stock car rules as they now exist. It is a good guess that the 1910 definitions will show some changes.

Heinze Was the Man in Demand—If anything went askew or anything reqnired attention, the man searched for was the indefatigable Heinze, the carnival president, who was here, there and everywhere at all times. To John O. Heinze credit belongs for the creation of a great race meet, and the city of Lowell is now known far and wide for its progressive automobile spirit and ability to provide for one of the most successful series of competitions ever held here or abroad.

Hower as a Referee—The meet signalized the initial appearance of Chairman Hower in the referee's role, the reason for his taking the position being the national character of the racing. 'Tis understood that Chairman Hower has had his fill of honors in the competitive field of automobiling, and some time ago he gave utterance to the statement that he would not seek or accept a continuation in office. Even those who have disagreed with Hower credit him with energy and persistence.

Press Arrangements Excellent—Under the direction of Lewis E. MacBrayne, chairman of the publicity committee, the arrangements for the men who told the story of what happened could hardly have been improved upon. There was plenty of room in the capacious press stand, an abundance of wires and operators, with refreshments available when the workers felt the need. To make comfortable and facilitate the activities of those who write the tale is wisdom for the management of any affair, be it great or small.

President Speare Unobtrusively Prominent—One who had no small part in the proceedings was Lewis R. Speare, the A. A. A. chief executive. New England supplies much strength to the national body, and its scenic grandeur and miles of excellent roadway attract thousands of auto tourists. There is as much pride of country as in the more vociferous West, but it is expressed in a lower though no less determined key. President Speare is a Bostonian with a family-tree that finds its roots in the landing of the Pilgrims, and his accession to the leadership of the A. A. A. naturally found much New England approval.

The Door of Opportunity—In the races of 1908 there assisted in the guarding of the course, Patrolman George H. Brown. In the races of 1909 Mayor George H. Brown and Mrs. Brown, his former stenographic secretary, surveyed proceedings from the municipal box in the grand stand. Of course, it must be said that the present mayor made an exceptional patrolman, and the opportunities of politics did the rest, in opening the abrupt door to the mayoralty of a manufacturing city. His candidacy was not taken seriously until too late, and then the votes were in process of being counted.

"Lowell's Vertebrae"—A mile of brick cotton factories that line one bank of the Merrimack river, is what Secretary John A. McKenna, of the local automobile club, called "Lowell's vertebræ" in the historical sketch of the city, which has a hundred thousand folks, and includes about 8,000 Greeks who live in a section by tbemselves. One can see the house in which Whistler, the artist, was born, and also the former homestead of Gen. B. F. Butler. The old Spaulding house, once used as a tavern and now occupied by the Daughters of the American Revolution, is referred to as an example of the excellent architecture of colonial days.

Some Thrifty New Englanders Who Profited—Certainly such a catchpenny opportunity never before arrived in New England. Several times bigger, actually, than any country fair or circus, because of the number on the scene, and much bigger, theoretically, because of the class of those in attendance, the field for merchandising appealed to both the peripatetic fakir and the thrifty native as the chance of a lifetime. Everything that Yankee wit, stimulated by prospect of profit, could think of, was for sale, and the prices were low. One man near the grandstand cut away prematurely a portion of his crop of corn in order to have parking space for a few cars, and no resident on the course was of too high estate to lease his ground to the sightseers. At Roberts' corner, one native had a fence of unbarked posts and wires, manifestly put up in a hurry. On the lawn within the fence were several signs: "Private Grounds—no trespassing"; "Autos and teams $1 parked here"; and these were cunningly flanked by the official sign of the Lowell Automobile Club, reading: "Danger! Keep Back of This Wire!" The owner probably expected the club sign to drive everyone inside his property line at a profit to him, but he had a merry time trying to live up to his "no trespassing" sign. He did a good business, though, and so did a neighbor who charged the sporty populace for a foothold on his stone fence, which was not at all of that New Jersey variety which dissolves the foothold.

"WALKERS" FOR CONNECTICUT HIGHWAY

HARTFORD, CONN., Sept. 7—For the inspection of the State trunk highways, there will soon be fully installed a system almost as thorough as on a railroad. State Highway Commissioner James H. MacDonald has arranged to keep the newly constructed macadam sections under constant surveillance, having men whose duty is to watch the roads and when any little breaks appear fix them, and then report accordingly. The asphaltic oil, which was purchased recently, is now being distributed, work starting at Meriden, and the treatment will be closely watched. A great many automobiles travel over the routes through that city and the oil is to allay the dust rather than as a constructive binder.

Old Boston Post road from Greenwich to the Rhode Island border is being improved, including two of the worst sections of road in this State. The Saybrook Ferry road, which is generally considered bad, is also being repaired, and the East Lyme stretch over the river is likely to be bettered very shortly.

STOCK CARS FEATURE WILDWOOD'S LABOR DAY RACES

WILDWOOD-BY-THE-SEA, N. J., Sept. 6—No speed records were broken this afternoon in the maiden meet of the youthful North Wildwood Automobile Club, but with 28 separate dashes over the mile stretch on Ocean avenue there was a well satisfied crowd of spectators and club members. For two and a half hours, the broad roadway was roped off for the contests and there were sufficient machines all told on hand to furnish a good day of fast sport. The regular Labor Day crowd of many thousand people was also in evidence, but there was no trouble in keeping them back for the route of the autos, and, in fact, the entire management of this event elicited great praise. The new clubhouse has made this Jersey coast resort more of a rendezvous for the automobilists from the Quaker City and neighboring points than ever before.

Willie Haupt, in the six-cylinder Alco, and Joseph Parkin in a six-cylinder machine of his own make, were the star performers, and, with the exception of the Parkin, all the competitors were stock models. Packards, Peerless, Cadillac, Overlands, Fords, Mitchells, Acme, and Pullman took part actively, and interspersed with the races between the four-wheelers there were some exceptionally fast ones for motorcycles. The Lowell carnival evidently kept some of the regular Wildwood entries away and prevented the possible lowering of records. The day was a perfect one for speed, except for a head wind, and that difficulty was overcome by allowing the fastest of the cars to show their abilities in both directions.

It was the wind direction and the running over the course both with it and against it that gave Willie Haupt the honor of the fastest time of the afternoon. In the time trials the Parkin was sent down the mile first, and its time caught at :54 4-5 as against the :55 seconds of the Alco 70. When the officials gave the motorcyclists the privilege of running with the wind, with a difference of five seconds in their time, it was agreed to allow Haupt and Parkin to do likewise. The former was thus able to win out, for his big car reduced its time to :51 1-5 seconds, an average of 70.3 miles per hour, while the Parkin's record was :52 4-5. In the free-for-all, however, the latter finished the mile fully 40 yards ahead of the Alco, in :55 1-5. These two machines were the only under-the-minute ones present, although Parkin sent a Packard roadster down the line in a minute flat. What was lacking in sensational speed was made up in the exciting finishes, for in a number of the events the machines were remarkably well matched and crossed the line with but a few feet or inches separating.

R. A. Jackson's Mitchell 20 just managed to nose out H. F. Hunter's Overland in the $1,250 and under event, with the 22-horsepower Ford, driven by E. S. Byam, but a length in the rear. The winner's time was 1:18. The Cadillac's victory over the Mitchell in the $1,251 to $2,000 class was similarly close, the former covering the distance in 1:10. Another eyelash race was witnessed in the triangular contest between the Peerless, Acme, and Packard in a special event—put on to fill a gap for cars in the $3,001 to $4,000 class, which did not appear. The Peerless, belonging to Ben Griscom, was driven by R. H. Nimms and was but a scant wheel length ahead of the Acme, driven by J. W. Ely, while the latter was but 10 yards ahead of J. W. Beck in the Packard. Another filler was a match race between a 40-horsepower Pullman, driven by J. L. Brown, and a 30-horsepower Overland, with H. F. Hunter at the wheel. The York-built machine won by about 20 yards, its time being 1:11 4-5. A consolation event brought out all the non-winners and was annexed by Beck's Packard in 1:23, with Joe Parkin in a Mitchell and Byam in the Ford as runners-up.

MINNEAPOLIS AUTOISTS HAVE EXHIBITION

MINNEAPOLIS, MINN., Sept. 4—This city will open the automobile exhibition season next week, in connection with the State fair, for a mammoth auto show will be held in the new grandstand building. This huge concrete structure has an exhibition room 300 by 150 feet in size, one side of which is composed entirely of windows. The following makes of cars have been placed upon the list: American, Pope-Hartford, Reo, Holsman, Chalmers-Detroit, Hudson, Thomas, Velie, Elmore, Inter-State, Pullman, Winton, Peerless, White, Cadillac, Rapid, Black, Columbus, Frayer-Miller, Mora, Halliday, Mitchell, Chase, Minneapolis, Regal, Midland, Pennsylvania, Richmond, Jackson, Maxwell, Hupmobile, Brush, Schacht, Detroit, Wilcox, McIntyre.

Hundreds of people visit this fair during the week, and the automobile and accessory concerns always do an immense amount of business. On Saturday there will be races on the track.

STATE GOVERNORS INTERESTED IN ROADS

The replies from Governors and Mayors of many States and cities to invitations asking that delegates be sent to attend the second annual National Good Roads Convention bear eloquent testimony to the growth of the Good Roads movement in all parts of the country. Although the tentative program and invitations were issued by the A. A. A. committee only a week ago, favorable responses have been received from the Governors of twelve States.

Governor Patterson, of Tennessee, sent a particularly interesting letter, stating that he had called a Good Roads convention in his own State to be held at the same time as the National Convention, and would also be represented by several delegates. The other States from which representatives have been promised are New York, Maine, Wisconsin, North Carolina, Maryland, Indiana, Arkansas, Nebraska, Kentucky, Iowa and Illinois.

Aeroplanes in Actual Contest at Rheims

by W. F. Bradley

Three Aeroplanes Racing Down the Homestretch at Rheims—Latham, Lefebvre and Bunau-Varilla

BETHENY, near Rheims, Aug. 30—Old Glory floats in the front row of a line of sheds facing the aviation ground on which the world has been shown that the aerial way is established. When the American team took up its quarters in the wooden establishment reserved for it, Glenn H. Curtiss pronounced conditions ideal for the aeroplane; his friend and assistant, Ward Fisher, passed a favorable judgment on the two sleeping rooms in the rear; Tod Schriver, ex-circus performer, now skilled mechanic and indispensable helper, did not care much what the accommodations were, but he must have Old Glory floating from the roof. A Rheims department store furnished the Stars and Stripes; Schriver scrambled to the top of the building, planted the flag, and the crowd came immediately. There is not an American on the ground who has not done his best to break through the line of gendarmes carefully guarding the enclosed camp where aeroplanes and aviators are housed. Many of them have succeeded either legitimately or otherwise in procuring passes that allow them to get a closer look at the flyers. All day long it is a procession of people from the other side of the water anxious to look at the machine and wish its pilot good luck. Cortlandt Field Bishop, as stockholder in the Herring-Curtiss Company and president of the Aero Club of America, is daily on the spot. The American automobile world is well represented by Jefferson De Mont Thompson, treasurer of the Long Island Motor Parkway; Roy D. Chapin, of the Chalmers-Detroit Company; H. L. Kittredge, of the Peerless Company, who has just been touring Europe on a 1910 Peerless, and various others. Royalty is not missing, many a member of the ruling families of Europe dropping in to see Curtiss and the American machine. President Fallières on his short unofficial visit found time to greet the American aviator and wish him success in the races.

There are thirty-eight aeroplanes on the ground, and as each one has a shed as large as the average suburban dwelling house a good idea of the size of the camp can be obtained. Some of the companies, as in the case of the Curtiss team, have fitted up their quarters as if for a permanent stay, with comfortable sleeping rooms in the rear, prints and flags on the wall, and an air of orderliness and cleanliness everywhere. Others let the aeroplane have all the space, leaving the shed at night stoutly barricaded and in the care of a watchman. Others again live in a piggish style, with a camp bed on the grass-covered floor, or with merely a mattress thrown inside a packing case, while butter and sardines and canned beef are mixed up indiscriminately with mechanics' tools, oil and grease; to complete the confusion a couple of horses may be stabled in one corner.

Down the line, a few yards from the Curtiss headquarters, is the Bleriot establishment. Though the two men have not yet exchanged a word directly, for Bleriot is ignorant of English and Curtiss has not been known to utter a word of French, there is a mutual sympathy and admiration between the two. Unlike the generally accepted description of the Frenchman, Bleriot is cold, calm, unemotional, possessed at the same time with a quickness of action and a stronger determination than most men. Bleriot was out for the Gordon Bennett cup and the speed test. Curtiss crossed the Atlantic with the same object in view. Thus though they are admirers they are also rivals. Curtiss puts his faith in a biplane, practically identical with the one with which he made flights at Morris Park and on Long Island, but equipped with a new eight-cylinder motor developing 30-35 horsepower. It is a light, handsomely constructed machine, with a lot of original details about it that call forth the admiration of the experts. Bleriot's best apparatus is a No. XII monoplane—the twelfth in the long series of machines he has constructed—fitted with an 80-horsepower E. N. V. motor.

This aeroplane is larger and much more powerful than the one which crossed the English channel. The wing surfaces are flexible and are mounted at the fore end and on the upper portion of a long metal chassis. Below them is a platform carrying the motor and the wide seat for pilot and one passenger. The space is so great that a second passenger could be accommodated without much difficulty. The eight-cylinder engine is of the V type, with cylinders cast separately, machined inside and out and capped with a jacket obtained by a system of copper deposit. This avoids the use of an independent head, with joints than can rarely be kept tight when running at full power for any length of time. To enhance its chances of success the engine is fitted with double ignition by high-tension magneto and storage batteries, both sets of plugs being in the head.

The drive is taken from the forward end of the crankshaft to a propeller shaft carried in ball bearings just below the wing, by means of a chain. The propeller, a two-bladed wooden one, is geared down about one-third. On the standard machine the gasoline tank is carried within the upper and lower surfaces of the wing, the fuel, of course, flowing down to the carbureter by gravity. As this machine will also be used in the endurance test a very much larger tank has also been fitted under the pilot's seat, holding enough fuel for a four hours' trip in the air. All controls with the exceptions of the vertical rudder, operated by the feet, are combined in a single steering column mounted on a universal joint and consequently capable of being turned in any direction. Throttle and spark advance levers are fitted just below the steering wheel. The gasoline pressure pump and supplementary oil pump are at the pilot's right hand.

Bleriot has a second and similar machine fitted with a powerful three-cylinder Anzani motor, which like the first has transmission by chain to a ball bearing shaft carrying a two-bladed wooden propeller. It was with this machine that he qualified for the Gordon Bennett cup, but was later unable to get much speed out of it. The motor persistently heated despite all the attention given to it by the mechanics. After a thorough examination by Anzani it was discovered that it was geared too low. Thus constantly racing with a higher gearing very satisfactory results were obtained. The same type of motor, but of much smaller size, was employed on the cross-Channel flight and is fittetd to three duplicate machines used here. Anzani disposes his three cylinders fan-wise, connecting all three rods to one crank and employing internal flywheels as in the standard type of single-cylinder vertical motor.

Up to the present the most successful motor here is, strangely, the newest and most freakish. It is an air-cooled Gnome with seven cylinders, which revolve together with the crankcase, the hollow crankshaft being stationary. Up to the present this motor has never "laid down" in a race. Practically every part is machined out of solid bars of nickel steel. Even the cylinders are produced in this way, being first roughly shaped out, their fins formed and profiled so as to give greater depth at the top than at the base; then the inside is hollowed out, giving a shell very much lighter than can be obtained by casting and at the same time of greater strength than any cast cylinder.

The method of attaching is original, each of the cylinders passing through a hole bored for it on the face of the circular nickel steel crankcase. They are secured by a locking ring on the inside of the case. With the cylinders and case revolving together the tendency is for the former to be pulled out of their case. A locking ring round the base within the casing is therefore all that is necessary. The exhaust valves are in the cylinder head, operated mechanically. The inlet valves are in the piston head, operated automatically. The crankshaft being fixed and hollow is employed for the admission of the explosive mixture into the crankcase and through the piston head valves into the combustion chamber. Ignition is by a standard type of high-tension magneto specially geared to provide seven sparks for each two revolutions of the engine.

There are a few machines here using practically a standard type of automobile motor somewhat lightened for aerial work. Henry Fournier was one of these, with an Itala of four cylinders developing 40 horsepower and lightened in its accessories only. Even the radiator was the absolutely standard type as used on automobiles. Vivinus furnished a practically standard type of four-cylinder automobile motor for aeroplane work, fitting it to two of the machines entered by Henry Farman.

Up to the present it has been impossible to learn any really practical lessons regarding the respective merits of the standard heavy and the special light-weight motor. In both classes there have been striking successes and partial failures. One point that has been clearly proved is that it is not really necessary to obtain a feather-weight engine in order to rise from the ground.

Castor oil is very extensively employed for lubricating the aeroplane motors. Bleriot uses it exclusively for both his small and large motors. All the Gnome engines use it for the main bearings. Employers of pure castor oil are unanimously of opinion that it is excellent as a lubricant. The only objection that can be raised against it appears to be that its smell is objectionable. Certainly the camp here at times smells as if a drug store had been set on fire.

America's share of the honors of the meet has been sufficient to show that this nation means to keep in the foremost rank of the new invasion of the air. There were some who thought that America's first and last word in aeronautics was the Wright brothers, and that the European nations, especially France, with her hosts of experimenters, would quickly regain pre-eminence. They have learned their mistake. The Wright machines played a prominent part in the meet, and Lefebvre, Tissandier and Lambert were among the most successful of the aviators, but Curtiss alone could easily have upheld the reputation of his country. In actual number of victories his machine was surpassed by Latham's Antoinettes and equalled by Farman's machine of his own construction, but the impression produced by the swift and sure "Golden Flyer" was second to none.

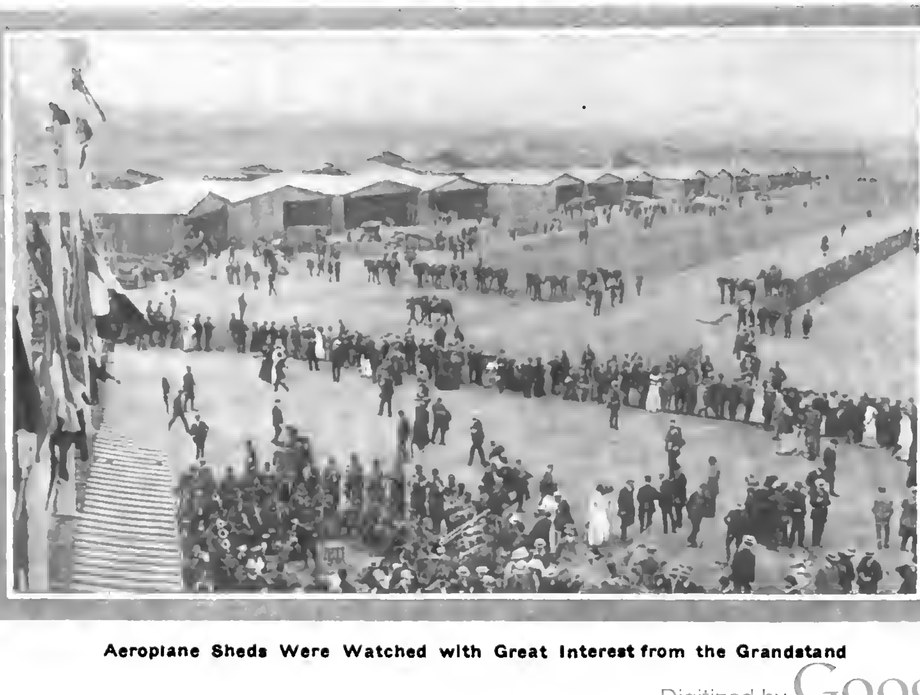
LEFEBVRE KILLED TESTING AEROPLANE

Juvisy-sur-Orge, France, Sept. 7—E. Lefebvre, who took a prominent part in Rheims week, was killed to-day by a fall while testing one of several new Wright aeroplanes which were being prepared for delivery. He was flying at a height of only 20 feet when the machine swerved sharply downward and struck the ground with great force. The cause of the accident is unknown.

WRIGHTS BUY LAND FOR AERODROME

Springfield, O., Sept. 6—Wilbur and Orville Wright have purchased about 700 acres of land at Tippecanoe City, near here, to use for their experiments with aeroplanes. It is reported that the brothers will erect an extensive factory and begin to manufacture their aeroplanes on a commercial scale.

Roy D. Chapin and Glenn Curtiss



Aeroplane Sheds Were Watched with Great Interest from the Grandstand

RESULTS OF WINNIPEG AGRICULTURAL MOTOR TRIALS

THE Winnipeg Industrial Association conducted its second farm-motor competition with an entry list of 22 machines, of which 18 took part in the trials, and unusual interest was aroused both among the manufacturers and the farmers. The tests comprised a two-hour brake run, and demonstrations of hauling and plowing, and the machines were also carefully examined with respect to design and construction, accessibility and protection from mud and dust, ease of operation, and clearance of working parts from the ground. The type included both internal combustion and steam; the former were divided into three classes, according to horsepower.

For the brake test a special rope-brake had been constructed by the engineer in charge, and this was applied to each mottor in turn. Careful records were kept of the load applied and the speed of the motor, its consumption of water and of coal or wood, if steam, and of gasoline or kerosene, if internal combustion. These tests averaged in length two hours. The hauling demonstration was held over a soft and gravelly piece of ground half a mile long, which was traversed about ten times by each machine. The load, distance, time, fuel consumed, and drawbar pull were recorded. The plowing test was extremely interesting, although the results depended as much on the plows as on the tractors. Full results of all the tests are given in the table appended below.

Official Records of the Entries and Results in the Second International Trials for Agricultural Motors held at Winnipeg, from the 8th to 17th July.

Class A, Internal Combustion (20 h.p. and under); Class B, Internal Combustion (20 h.p.—50 h.p.); Class C, Internal Combustion (over 50 h.p.); Class D, Steam.

RECENT FRENCH MOTOR PLOW TRIALS

PARIS, Sept. 1—Agriculturalists will have an opportunity of seeing how plowing can be done without the aid of horses or oxen at an exhibition to he held at Amiens on September 24. The occasion is an international competition and motor congress intended to develop the use of the internal combustion motor in agricultural pursuits. In the motor plowing match each of the competitors will be given a piece of land on which to operate, the classification being established on the manner in which the plowing is done, the cost per acre, the time necessary to bring the machine to the field and put into operation, the number of men required, the facility with which work can be done on varied land, and the possibility of using the motor for other work on the farm.

This is the second occasion on which a plowing competition has been held in France, the first being last year at Bourges. In order to encourage the use of motors on farms it has been decided that a series of exhibitions, competitions and congresses shall be held, a different center of France being selected each year. Up to the present French constructors have not paid very close attention to the development of very simple motors for use on farms, or to motor-driven or steam plows. In the last competition America and England were well represented, and will figure again in the Amiens competition. French entries will doubtless be larger than last year. Too much credit cannot be given the French nation as a whole for the tests of this nature, which they hold every year and in every branch of the industry. These tests lay the foundations of good business.

DIRECT INJECTION OF FUEL FOR MOTORS

That direct injections of fuel have the advantage of weighing out an exact amount of the same is self evident, and since the weight of fuel injected may be varied at will, it is plain that there is a considerable advantage attending the method providing the time of injection can be altered at will. It is easy enough to measure out the required weight of fuel, if a plunger pump is used, especially provided the packing question is well cared for and there is no leakage of moment. The length of the stroke of the plunger may be changed at will by means of a sliding cam motion, and if the cam is also given the ability to lag, or lead, which is but a question of supplying the necessary mechanism, just as is done with ignition systems; it then becomes possible to measure out the fuel, with great accuracy, alter the quantity of the same, at will, and fix the time of injection to suit the conditions. Under the best conditions the amount of gasoline required is about two per cent, by weight, of the total volume; but to attain flexibility, it is necessary to vary this ratio over considerable ranges.

Not only is this subject being discussed very thoroughly, but many experiments are being made with engines fitted with a fuel injection system. As these are tried out one by one, their success spurs other manufacturers on to try the same thing, and so the list of engines using the direct injection gains in numbers daily. Thus far, however, it is in the field of two-cycle motors that the greatest advance has been made. But the success there will before long have its direct result upon the more reliable and much more general four-cycle form.

AUTOMOBILE WHEELS, RIMS, AND TIRES

By Thos. J. Fay

FROM A MUMMY PIT DATING BEFORE 2000 BC

FIG. 15 FRONT

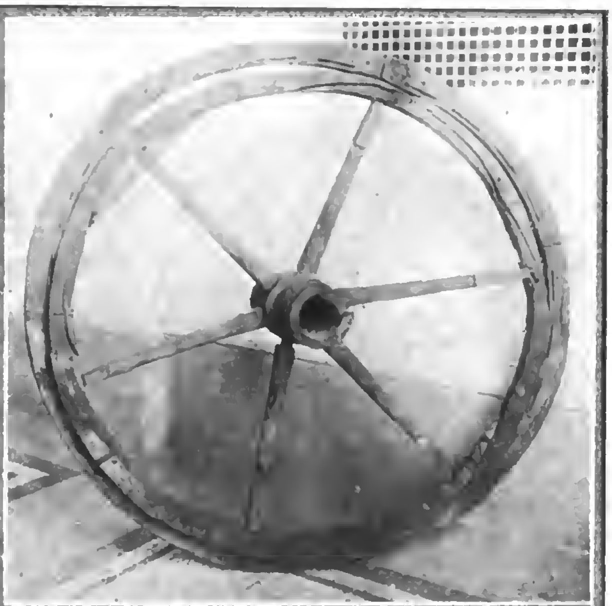

FIG. 16 BACK

THE NINEVEH WHEEL-EGYPTIAN

FIG 17

EGYPT, as a land of silence and mystery, indicates to the investigator with eyes to see the silence of consummate intelligence and the mystery which must ever remain in the maw of forgotten centuries. For over 30 years the New York Historical Society has had in its possession what is catalogued as the "Nineveh" wheel, which was taken from a mummy pit by Doctor Abbott, at a point near Dashour, in Egypt, which wheel upon examination proves to be the direct ancestor of all spoked wheels as they are now made.

The date of making of the Nineveh wheel cannot be exactly fixed, but Dr. Abbott estimated its age to be not less than 4,000 years, and the indications are that the date of interring of the once mortal, or mummy, was about 2000 B.C. The wheel is here shown in photographs taken especially for THE AUTOMOBILE by permission of the director of the New York Historical Society, and Fig. 15 represents a front view of the wheel; Fig. 16 depicts the wheel from the back, and Fig. 17 is with the wheel on edge, in order to depict the dish of the spokes, which is apparently very large.

The hub of this wheel was turned from a solid block of wood, is about 18 inches long in the axle plane, and the enlarged portion at the center is about six inches in diameter, dropping down to four inches at the approach of the two ends. The wheel is provided with six spokes, terminating in six felloe segments, and the tenons come at the joints of the felloe sections. The wheel is about 40 inches in diameter, and the tenons are nearly square, fitting into square sockets both at the hub and at the felloes.

Demountable Rims Invented by the Egyptians—This wheel is provided with an outer rim of bent wood, which serves as a tire, and since it is bound on by means of wrappings at six points around the periphery, with T-shaped slots provided in each spoke for the purpose, it has all the advantages of a demountable rim. This rim was evidently bent by artificial means, and that it could be removed and replaced at will is one of the evidences afforded by an inspection. In a word, then, the Egyptians used wooden tires and provided for their prompt replacement as the occasion required. This particular wheel was probably used on a chariot. The views given show the markings of great age, and that the wheel was much used before it was placed in the mummy pit by the ancients is scarcely to be believed.

What Went Before the Nineveh Wheel—What sort of

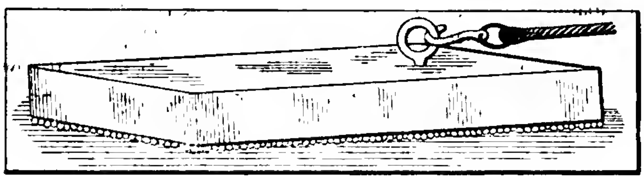

Fig. 18—Showing How Heavy Weights Were Once Moved

wheels, or equivalents, rolled over the causeway leading up to the Great Pyramid 4000 B. C. is not clear to us, but Fig. 18 represents a logical suggestion; brute force, so to speak, aided by crude ball bearings wrought out of the sands of the desert, probably did have something to do with it. Imagination, tuned up to the occasion, leads to the roller bearing system as depicted in Fig. 19, and from this point on to "Nature's own" wheel, as shown in Fig. 20, is but a step.

Modern Wheels Differ in Point of Detail—History, leading down through the halls of time, records the days of ornamental wheels, reaching their height during the seventeenth and eighteenth centuries, but these wheels were not dished, and they differed materially from the Warner or Sarven style of wheel of the present day in that the lion's face or other ornamentation is erased from the hub, but strength is substituted instead.

If the Egyptian invented the first wheel, it was the American who brought it out of its earlier stage, introducing all the features of strength, simplicity and utility, of which exact knowledge is now in the possession of wheelmakers. Take a wheel of the present, for illustration, and load it down, when, lo, it will be found that five tons will be safely borne by a wheel with spokes no more than three inches wide at the flange in the axle plane.

Wheel Diameter Represents an Important Point—The Egyptian wheel shown in Fig. 18 is 40 inches in diameter; wheels for extremely heavy trucks have been made even 100 inches in diameter, and in this respect the practice, depending upon the requirements, has varied over broad ranges. For automobiles, owing to the splendid service rendered by pneumatic tires, coupled with the cost thereof, diameter has fallen away to a low ebb, reaching the low limit of 26 inches in a few cases.

That small wheels, even below 32 inches, represent much economy is not readily proven by past performances. For a very light, relatively slow speed runabout, it may be that 28-inch wheels (measuring over the tires) will do very nicely, but the trend is back in the direction of the (former) large-diameter wheels, despite the finer qualities of modern tires, which rather goes to show that the cost of tires had more to do with reducing the diameter of wheels than any other one thing. This cost of tires is curing, and quality, which is also a point to be enlarged upon, is advancing about in the same ratio that cost is reducing. In this is seen a double advantage, which enables builders of cars to increase the diameter of the wheels, and in so doing augment the easy riding qualities of the cars, reduce spring troubles, and gain advantages in other ways, leading to longer life of the cars as a whole. This statement of the cost of tires does not contemplate any discussion of the moment, as the rise and fall of the rubber market and the relating incidents are too well known to require it.

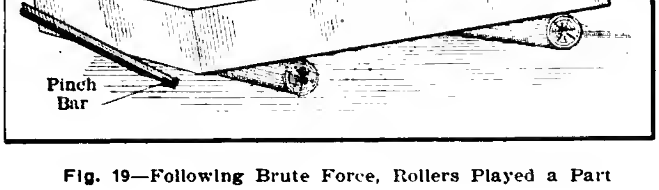

Fig. 19—Following Brute Force, Rollers Played a Part

In a general way the ability of a wheel is proportional to the square of the (section) diameter of the tire it will accommodate and to the circumference of the tire used. There must be a point beyond which this rule will fail to respond advantageously, since the centrifugal force, which will set up fiber strains in the tire, will increase with the diameter of the tire used, considering a given road speed of the car. That centrifugal force and its effect on the tire should be taken into account is quite as true as it would be of a flywheel for the motor or any other revolving mass. The right diameter of a wheel then involves all the conditions, as follows:

(A) Diameter of the tire in proportion to the height of road obstructions it will have to surmount.

(B) Section of the tire in proportion to the road debris it will be expected to "swallow."

(C) Section of the tire in proportion to the load it will economically sustain in actual service.

(D) Diameter of the tire as it relates to the load to be sustained.

(E) Diameter of the tire as it relates to centrifugal force.

(F) Weight of the wheel as a whole in view of flywheel effect on the car.

(G) Weight of the wheel as a whole from the point of view of gyroscopic action.

(H) Diameter of the wheel, taking into account the difficulty involved in removing and replacing tires.

(J) Diameter of the wheel, considering resilience, allowing that as the tires are reduced in this property, the wheels must make up for the deficiency.

(J) Diameter of the wheel as it affects cost, taking into account the cost of tires.

Obviously, in view of all these, and other conditions besides, there is justification in going slow, and time only will measure the ultimate diameter of tires such as will spell finality in automobile work. Progress in this work dates from the reign of a Pharaoh of the fourth dynasty, but the upward ascendancy of the curve of progress has taken most rapid strides toward the long-sought goal within a few years.

Diameter of Wheels Relates to Height of Road Obstructions—If a wheel encounters an obstruction equal to its own radius, there is no tendency to surmount, because the resolved forces must be summed up as a problem in impact calculations of the first magnitude, in relation to which it would be of small advantage to pursue a further investigation, since the car would have to go in any but the forward direction. But there is some angle of impact which may be encountered with impunity, which angle will be nearly the same for all wheels of whatever diameter, but the higher the obstruction the greater must be the diameter of the wheel, in order to come within the fixed (maximum) angle of impact.

It is possible to consider that the versed sine of the angle of impact of a road obstruction with a wheel, allowing for pneumatic tires, will be allowable when the versed sine is some proportion of, but less than, the section diameter of the tire, which proportion, in turn, will depend upon the area of the section of the tire and the speed of the car, considering a given blow struck. In thus reasoning, it is necessary to take into account the nature of the roadbed over which cars must roll, but, after all, this is one of the prime requisites, and the proof lies in every effort at road building, since if cars could be made to negotiate Naurres byways, road building would languish.

Tires Swallow Small Road Debris—There are two ways of annulling the ills of small road debris, and speed may be increased in proportion to the versed sine of the angle of contact of rigid tires with such debris, or if pneumatic tires swallow the debris, speed may be increased up to the point where the debris becomes too large for the tires to swallow. In the absence of pneumatic tires, increasing diameters of wheels allows of increasing speed from this point of view, simply because the angle is reduced. The mere employment of pneumatic tires will not eliminate the tendencies, and, in a general way, increasing the diameter of pneumatic tires will allow of increasing speed, independently of the ability of the tires to swallow the debris. With pneumatic tires the gain is a double one, however, primarily due to the natural advantage of large diameter wheels, and, again, in view of the ability of the large tires to swallow the small, road obstructions.

Centrifugal Force Limits Diameter of Wheels—In the list of conditions which affect wheels, C and D remain as tire problems, and will be reserved for discussion later. The condition E, however, is abstract, since it affects wheels, no matter of what material they are made. In a cast-iron flywheel, when the rim speed is one mile per minute, the stresses set up in the section of the iron are all that it is safe to engender, if a factor of safety of suitable magnitude is to be retained. It is not in wood that danger is to be encountered when reference is had to flywheel effect, since in wood the rim strains is materially reduced, owing to the specific weight of the same, in view of its ultimate strength. For a given rim speed the extreme fiber strain is in proportion to the specific weight of the material used. The weight of ash, for illustration, is 34 pounds per cubic foot,

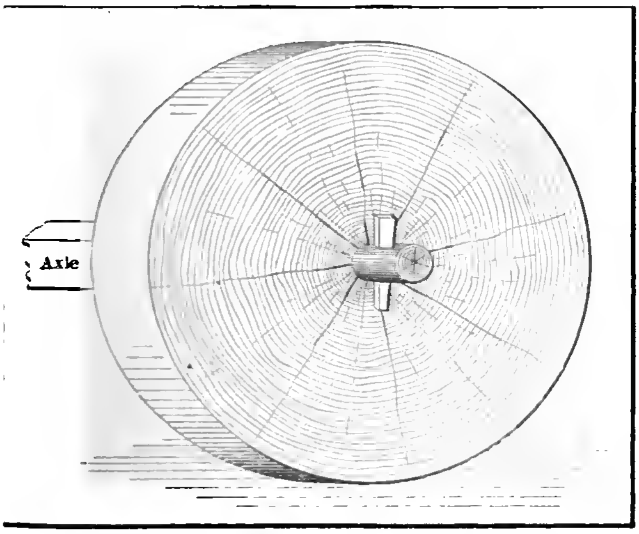

Fig. 20—From Rollers to Solid Wheele Was a Natural Step

whereas cast iron weighs about 450 pounds per cubic foot. In view of the relations, it has been determined that an ash rim will compare with cast iron for safety when the speed is increased to:

$\sqrt{10.58} = 3.25$ times the rim speed of cast iron.

The steel rims, as used with pneumatic tires, are not nearly so capable as the wooden felloes, so that the danger to be encountered, contrary to the usual expectation, is in connection with the steel rims rather than with the wood.

In flywheel work the rim is supported by the arms, which is not true when automobile wheels are considered, since the rims are not held by arms, unless account is taken of security bolting, which is frequently a negligible quantity. Considering steel, of which rims are made, centrifugal force (not counting the weight of tires) will tend to part the rim, one half from the other, and resistance is offered by the rim at each end of the diameter. The rim strain will be:

$S = 0.0000294\ V^2$

when

S = extreme fiber strain in pounds per square inch;

V^2 = square of the rim speed in feet per minute.

The above takes no notice of the weight of the tire, which loads the rim, since it is incapable of supporting its own weight, and an allowance must be made for this loading.

The extreme fiber strain is quite independent of the sectional area of the rim, so that the calculation assumes simple proportions, if only the speed of the wheel is known and its diameter is fixed, barring the error which is likely to follow if the weight of "loading," due to the weight of the tire, is not known exactly.

The limit of speed in revolutions per minute, considering different tire diameters, for a given maximum will be as follows:

MAXIMUM DIAMETER OF WHEELS FOR A GIVEN RIM SPEED

Revolutions per Minute	Diameter of Wheel	Speed in Miles per Hour	Rim Speed in Feet per Minute
672	30	60	5,280
612	33	60	5,280
560	36	60	5,280
480	42	60	5,280

It is not claimed that the rim speed above given will endanger the rims or the tires, but it may be well to consider that the strain is proportional to the square of the velocity, and double the above speed means that the strain will be multiplied by four. Just what will be a safe rim speed is yet to be determined, but the extreme fiber strain in the steel of the rim at a rim speed of 60 miles per hour will be:

$S = 5{,}280^2 \times 0.0000294 = 819.6$ pounds per square inch.

The above value, not counting the effect of "loading," seems to be well within the limits allowed for steel, and experience seems to prove that rims do hold out, even at double this speed, which is attained in racing. In the meantime, since speed imposes strains in a manner not usually considered, it may be well to ponder over this phase of the subject from the point of view of tire depreciation when cars are going fast on a hard, level road, and wheel depreciation when roads are not level, even if the speed is considerably reduced. Finally, with a method of reasoning sufficiently clear for the purpose, individual cases may be investigated with a view to ascertaining the factor of safety.

Weight of Wheels Must Be Considered—There are two ways of looking at the question of the weight of road wheels for cars—a, if flywheel effect is present to a noticeable effect it reduces the flywheel requirement, and, b, at high speeds of the car, if this same effect excess is in the road wheels, steering around curves will be attended by some approach to danger. Gyroscopic action, in so far as it is due to flywheel effect, will be present, no matter in which of all the members, the flywheel effect is induced, modified, to be sure, by the plane of the axis of rotation, so that each case would have to be investigated on individual merit. In the meantime, to whatever extent flywheel effect is necessary to the motor, it may best be supplied by a flywheel proper, because the speed of the motor crankshaft is higher than the speed of the road wheels, and greater flywheel effect may therefore be supplied with a lowering of the total weight of the car. Regarding the condition H, as before referred to, enough is to say it will be better to discuss sizes of tires and rims at the one time, a little later on. Resilience, as this property is tied up in diameter of wheels, is best represented in high-wheel cars using solid tires. That the high-wheel cars work very well is due to the resilience of the wheels, which property comes in through the use of long spokes, in which spring effect is most noticeable, and the amount of this action within limits is proportional to the cube of the length of the spokes.

That this resilience is destroyed when pneumatic tires are used is far from true, and this point alone augurs for wheels of considerable diameter, rather than the reverse. To whatever extent it may be possible to impart to wheels the property which makes it unnecessary to use pneumatic tires, also imparts longer life to the tires, since the amount of work they will have to do will be accordingly limited.

This point is one which might be well thought over by many otherwise promising inventors who are attempting to develop spring wheels. The one feature which all these wheels have in common is that they directly turn their backs upon this principle. No spring wheel has yet appeared on the market which was not heavier than the ordinary wheels, and of which the design was not such as to destroy every particle of natural resiliency which the wheel might have possessed in its original form. In this way the designers of these wheels were in reality adding to their task with each step they took. On the whole, it seems probable that the problem will work itself out gradually without making necessary any revolutionary changes.

(*To be Continued.*)

SOME CONVENIENCES IN THE OWNER'S GARAGE

PROFESSIONALS, if they deny themselves such facilities as would seem to be in keeping with progressive methods, make up for the deficiency by diluting their backwardness with skill. In the owner's garage an overcharge of skill is scarcely to be expected, and to trot to a repair shop every time some little thing happens is to run up a repair account which is likely to lend to autoing a reputation for cost, which is outside of the actual necessities.

If a nut is rusted in and fails to respond to a reasonable amount of pressure surely a can of kerosene oil may be ready to hand, and a little of the fluid, if it is spilled over the refractory nut, will loosen it in a little while; excess pressure, on the end of a long Stillson wrench, will, more likely than not, wrest the nut—with a part of the bolt clinging to it—from its home, and serve as the signal for a trip to a repair shop.

When a stud backs out during an attempt to take off the nut, to disregard the condition which underlies the incident is bound to lead to the loss of the stud and with, perhaps, the member the stud is placed to hold, and, rather than the resulting inconvenience, it is better to have in the garage a small quantity of hydrofluoric acid, a little of which, if daubed over the threads of the stud before screwing it back into place, will cement it into intimate relation and assure that it will remain where it belongs.

Rims, even if they are well coated with "japan" and baked will, in time, be attacked by rust, and, as the makers of tires are wont to say, rust is the bane of the fabric. In the owner's garage it is scarcely to be expected that facilities will be available for use in baking on japan, and there are no grades of unbaked japan that will stay on after rust forms on the rim. Fortunately, it is possible to cope with this problem, inasmuch as bees'-wax combines with rust and forms a new compound which prevents the further formation of the same. This same bees'-wax serves very well as a substitute for properly applied japan, and it may be easily put on, heating the rim, using a blow torch for the purpose. When this rim is heated sufficiently the bees'-wax may be spread over the rusted surfaces.

Strong Springs Render Valve Grinding Difficult—In some of the larger sizes of motors the valve springs are compressed to from 40 to 50 pounds, and in view of the cramped space in which they are nested many motorists prefer to have the valves ground in at a garage. A little experience of this kind generally leads to a period of leaky valves, rather than stand for delay which naturally results from placing a car in a busy garage, and the cost, which is frequently augmented by having other, and probably unnecessary, work done—a condition which is brought about by the mere delivery of the car into the hands of a repair man. True, every car should be kept in good repair, yet, even so, it is not good practice to make two bites of a cherry, and there is a class of repairs that can be deferred until the time when general overhauling is indicated by the condition of a car. Fig. 1 shows a spring puller of simple form, and by its use the spring may be compressed with but small effort, thus rendering valve grinding a relatively simple matter.

Keys Are Difficult to Remove—Unless keys are "driven home" they are likely to drift out at an unpropitious moment, and they will fail to do the work for which they are placed. When they are properly fitted, to remove them is more of a task than the average motorist is likely to admire, and Fig. 2 is offered as indicating how a key may be removed if in fashioning it the end is up-turned in order to allow of the placing of a "drift" piece and enable the mechanic to apply pressure in the manner as shown. Frequently, when keys are not properly fitted, they bear on the top and bottom, with the result that it is difficult to remove the wheel, drum or whatever it may be, but when the key is drawn the radial pressure is relieved and the drum may then be driven off with ease.

When a key has been taken out even two or three times, it is a question if it will then be valuable for future use, and while it may be peened to a new bearing thickness, and then refitted, even so it is better to have a little key stock on hand and fit a new key in place. In fitting a key, careful work will furnish its own reward; and, remembering that it is side pressure that is wanted, all that remains is to taper the key slightly, say 1-16 inch to the foot, and have a true bearing all along the faces. Blueing the pressure faces of the key will enable the mechanic to note, by trial, how tight it will fit by trial, and how well the face-bearings will be. When the key is ready to insert for the last time, it should drive nearly home with but relatively little effort, but the last part of the key, say for 1-2 inch, should resist with considerable tenacity. If the hub is of cast iron, and the shell is thin, it will be well to have a care in order not to split the hub, which will be a simple thing to do, in view of the slight taper of the key and the tremendous pressure it is capable of exerting. The lever advantage is in the ratio of 192:1 when the taper is 1-16 inch to the foot.

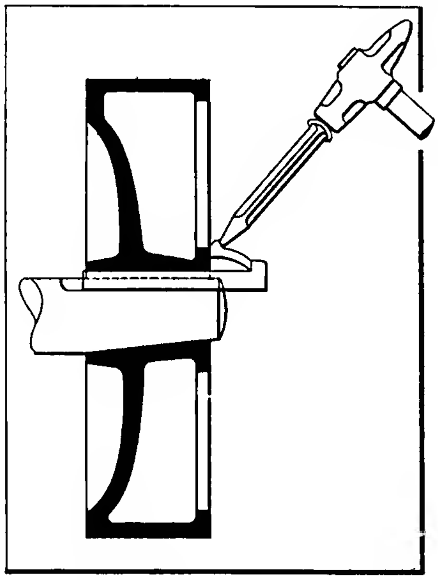

Fig. 2—Showing how key is removed

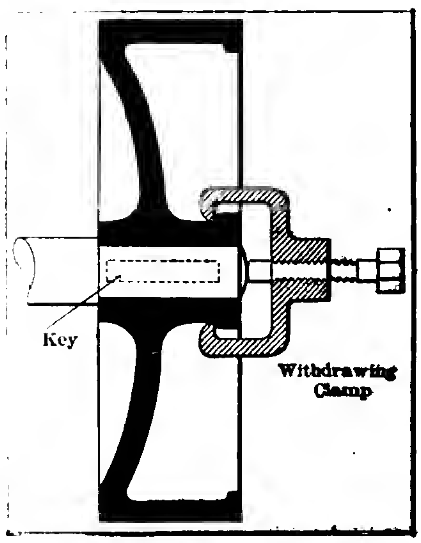

Fig. 3—Pull-jack of simple design

Meritorious Features of Wire Wheels

By Joseph A. Mackle

In the early days of the history of the automobile, solid-tired wire wheels were standard practice, and for the low powers and low speeds of those times the wheels gave satisfactory service. Less success was experienced when speeds increased, for owing both to too light construction and to undue imitation of the bicycle form of wheel—which, as shown below, is quite unsuited for automobile work—wire wheels gave considerable trouble and were soon replaced by artillery wooden wheels of the present day type.

One British car, however, had wire wheels of suitable design and shape even at that early date. This was the Lanchester, whose designers have seen so many of their distinctive ideas first ridiculed and afterwards generally adopted.. Such matters as three-point suspension, forced lubrication and worm drive of rear axle are all general developments of Lanchester practice, and, in passing, the opinion may be hazarded that further Lanchester features of tiller steering, wick carbureter, epicyclic gearing and uncanted front wheels are likely to find a good following in the near future. This reference to Lanchester practice is evoked by the fact that it was the excellence of the results given by those wire wheels that led the directors of the Rudge-Whitworth firm to study the advantages of this form. After lengthy experiment on the part of this great bicycle concern, the first Rudge-Whitworth wire wheels were fitted to the 90-horsepower Napier—the earliest six-cylinder racing car—which appeared in the British eliminating trial for the 1905 Gordon-Bennett race. The wheels showed their value by standing up when MacDonald skidded at high speed against the curbstone at Ramsey corner; but a still better proof was afforded later by Earp's 100-mile record ride at Ormond Beach, when he covered the last 63 miles on the rim, while in spite of this, the average speed was nearly 90 miles per hour.

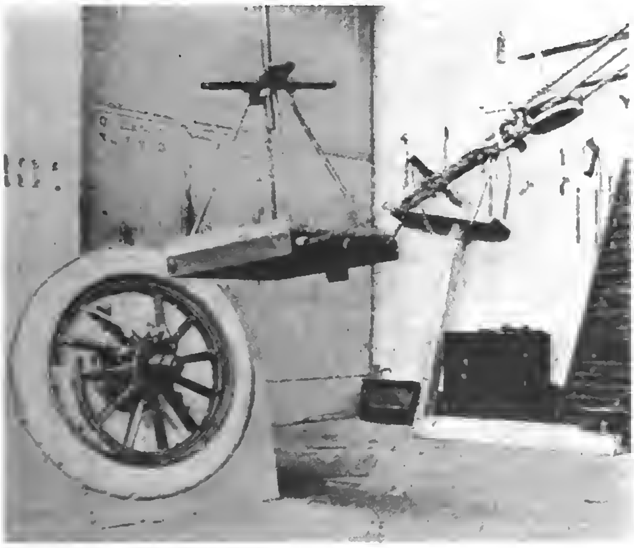

Fig. 1—Apparatus used in testing wire wheels

Such incidents showed the value of the wire wheel, and undoubtedly its popularity was assured, even if progress were slow. Meanwhile, however, the detachable rim had been extensively introduced for Continental races, and this suggested a detachable form of wire wheel. When the Rudge-Whitworth detachable wheel was at length placed on the market it immediately jumped into favor. Almost every make of car has been fitted with the wheels for special orders, while for this season the leading British firms—Daimler and Napier—fit Rudge-Whitworth wheels as standard on all their cars.

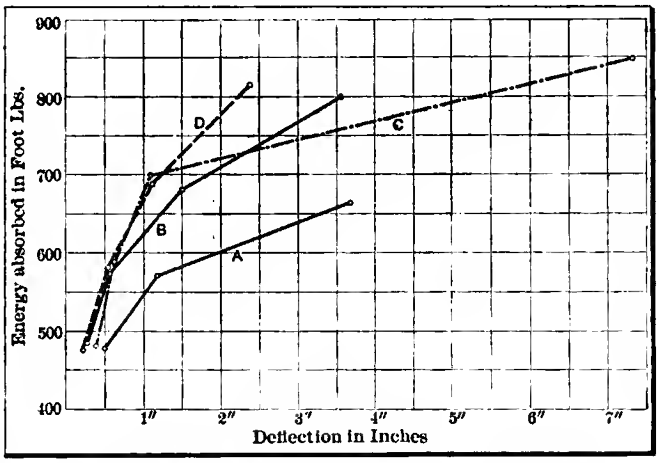

Fig. 2—Graphical showing of result of the first test

Edict Forbidding Their Use Proves Their Worth—Possibly the widest possible publicity obtainable was given to the wire wheels by the refusal of the Commission Sportive to allow the Napier cars to use these fittings in last year's Grand Prix race at Dieppe. Under these circumstances, S. F. Edge withdrew his cars, and his action was endorsed by the failure of several of the French cars through defective detachable rims. The embargo on the detachable wheel was withdrawn after the race, but as there has been no big European contest since then, the wheels have not had an opportunity to demonstrate their superior value in this very severe service.

The advantages of the wire wheel lie in its strength and lightness, while equally obvious are the special benefits accruing from the detachable form. A change of wheel can be made inside the space of ten seconds—this, of course, exclusive of the time occupied in jacking up the wheel axle. This ease of changing is not only of service in case of a puncture or blow-out, for by

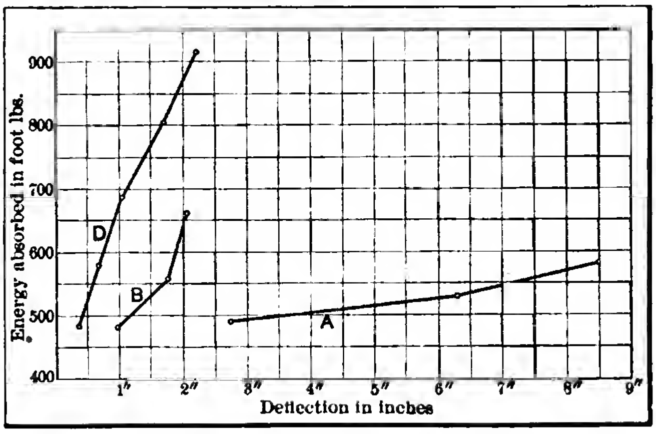

Fig. 3—Second test showed wire wheel superiority

Fig. 4—Wheel B as it appeared after the test

carrying a couple of, or even one, spare wheel with studded tire, the car becomes equally prepared for wet roads or dry.

A set of 888 x 120 mm. wire wheels weighs about 50 pounds less than the corresponding wooden artillery wheels, and the lessened weight of rim seems to have a saving effect on the tires. Particularly is this noticeable on rough roads through the absence of pounding. The greater ease of cooling through the rim serves in a notable degree to prevent the tires from becoming unduly heated at high speeds. Extremes of temperature and climate exercise an extremely deleterious effect on wooden wheels, however well the timber has been seasoned, and for this reason in particular wire wheels are now specified on all British cars required for export to the colonies. Wood is beginning to be reckoned an unreliable and unsuitable material for standing the abnormal stresses to which every automobile part is subjected, and following on its early abolition from the frame, wood has given place to steel, aluminum, and pressed steel for body work, and it is now being succeeded in most cases by steel wire for the material of spokes used in the road wheels.

In view of the fact that the strongest claim made for the wire wheel is its ability to withstand a side blow, such as would be occasioned by a sideslip against a curbstone, it is interesting to refer to certain tests made at the Rudge-Whitworth works under the observation of disinterested experts.

Disinterested Tests Prove Claims Beyond a Doubt—A heavy weight was suspended by a rod from the roof in the manner of a pendulum, in such a way that with the rod in a vertical position the weight rested against the rim of the wheel to be tested, while the wheel itself was supported on a dummy hub. The pendulum was then drawn up to a predetermined height and suddenly released, so that a heavy blow was given to the rim of the wheel. Successive blows increased in magnitude, and the results are shown graphically in Fig. 2. The wooden wheels indicated at A and C were greatly distorted after the first two blows, and at the fourth blow, wheel C collapsed altogether. The wire wheels B and D show only a slight advantage over the wooden wheels for the first blow, but subsequent heavy impacts have comparatively small effect, and even with the maximum deflection that was produced, the rims retained their circular shape to a considerable extent, so that they would still be capable of supporting the weight of the car. A further test of the three wheels was made by striking the rims at a point diametrically opposite to that of the first experiment. The wooden wheel, A, quickly collapsed, but both wire wheels gave substantially the same figures as in the previous test.

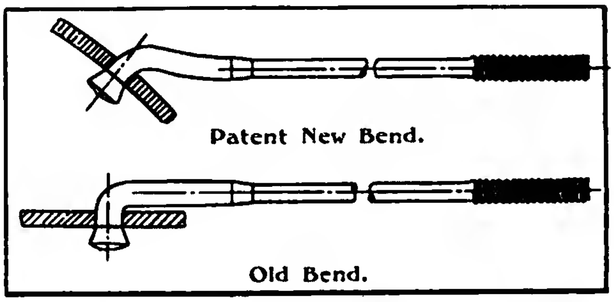

Fig. 5—New and stronger shape given to the spokes

Experiments of this kind have led makers to guarantee that a wheel of 888 x 120 mm. size (practically 4¾ x 35 inch), weighing 20¼ pounds, with rim, spokes and nipples, will sustain without damage a side pull of 6,000 pounds applied at the rim. The best artillery wheel yet tested, weighing 31½ pounds, would not sustain more than 4,500 pounds. This amounts to an advantage in strength (guaranteed) of 33 per cent. in favor of the wire wheels which are over 35.7 per cent. lighter in weight.

Regarding the construction of the Rudge-Whitworth wheels, the two rows of spokes are not yet symmetrical, as in the case of a bicycle. The stresses set up in a car wheel, particularly when rounding a corner, are very much greater from the outer than from the inner side of the wheel. For this reason the wheels are considerably dished, so that the outer spokes follow a much sharper cone than the inner. This displacement of the center line amounts to ⅞ inch in a wheel size 888 x 120 mm. Furthermore, in the case of driving wheels, the outer spokes are made tangential to a much smaller circle than the inner spokes, so that the latter take the major portion of the driving stresses, leaving the outer spokes free to resist the side stresses

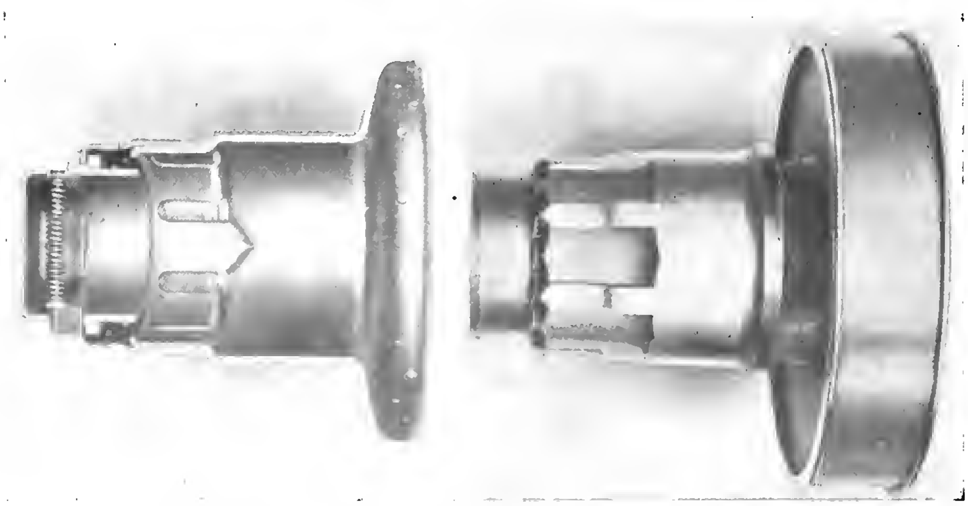

Fig. 6—Inner and outer hubs of detachable wheel showing driving keys

Improved Spoke Shape Increases Strength—In an 888 x 120 mm. wheel, which is the most popular size, there are 60 spokes, these being equally divided between the inner and outer rows. The spokes are made of 8 gauge (British) steel wire, swaged to 10 gauge at the centres. The heads are bent only through 45 degrees instead of 90 degrees, as usual. This simple alteration, shown in Fig. 5, has been found to decrease very greatly the liability of the spoke heads to break away owing to vibration, and, as a matter of fact, this construction leaves the metal with 90 per cent. of its ultimate strength in place of the 75 per cent. that the 90-degree spokes have.

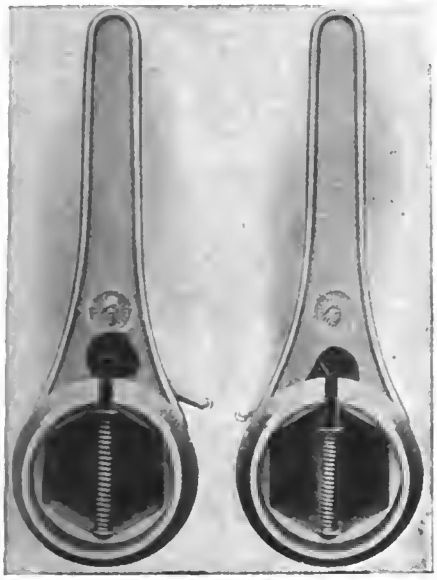

Fig. 7—Two views of spanner used on Rudge-Whitworth Wheels

The construction of the detaching mechanism will be evident at once from a glance at the illustration. The inner hub takes the drive in the usual way, it being immaterial whether this is by shaft or by side chains. This hub also carries the brake drums, speedometer rings, and other like fittings. Integral with the body of the hub are eight projecting keys, milled up out of the solid. The hub of the wheel itself consists of a shell which is internally grooved so as to make a sliding fit with the keys of the inner hub. A triangular pilot piece in the hub shell insures that the keys shall enter into the slots straightway, no matter in what position the wheel may be pushed on to the hub. When the wheel is in position the hub cap, which is permanently secured to the wheel, is screwed up by a special spanner until the wheel is felt to be securely home. The small lever visible in the illustration of the spanner is then thrown over, and a pawl, which has hitherto been held out of action, is now released and engages with a notch in the hub, securely locking the whole arrangement in place. Until this pawl has been released by the lever, the spanner cannot be removed from the cap, so that it is impossible for anyone to forget to make use of the locking device. Several other arrangements of locking pawls have been employed, but all work on similar lines to the above; for example, the latest wheels have a simple ratchet internally cut round the edge of the wheel hub and a spring pawl on the lock nut. When the wheel is in position no backward movement of the cap is possible till the spanner is used to depress the pawl.

Rudge-Whitworth detachable wheels are now only made in wire, although the detachable principle could as easily be applied to artillery wheels, and, this has been done in a few isolated cases.

Use Not Confined to One Firm, but Is General—Several other firms have recently introduced types of detachable wheels, usually both the wire and the wood forms being supplied. The Humber wheel is probably the best known, and is locked in place by a screwed cap with a spring locking device, shown in Fig. 8, and consisting of a spring actuated bolt which connects the hub cap to the wheel proper unless held out of position by the special withdrawing spanner. These had the test of racing experience in several Tourist Trophy races before being accepted.

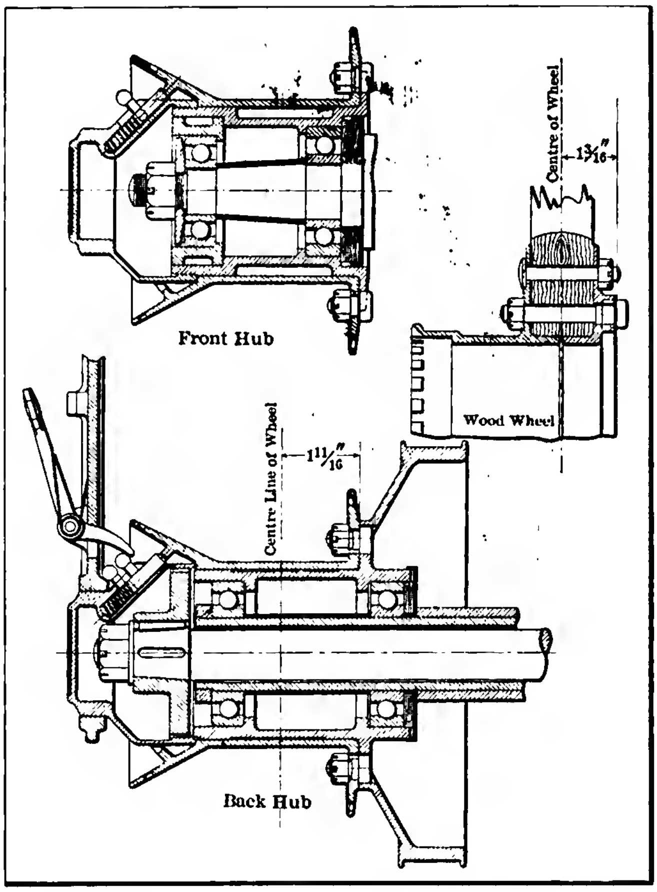

Fig. 8—Construction of the Humber wheel, which is new

Other British detachable wheels are the Riley and the Harper. Both these are similar in construction to the Humber, and are fitted respectively to the Riley cars and to the S. C. A. T.—an Italian make somewhat popular in this country (England).

22-Horsepower Daimler with Silent Knight Engine and Rudge-Whitworth Wire Wheels

LETTERS INTERESTING

VALVES AND CLUTCHES

Editor THE AUTOMOBILE:

[2,002]—Will you kindly inform me through "Letters Interesting, Answered and Discussed" as to the following matters:

1. How does the slide valve spoken of in Letter 1,982 differ from the ordinary?
2. How does a coil spring, Mercedes type of clutch, that was used on the Maja car in the Briarcliff Cup race, differ from the cone clutch as used on the Renault car?
3. Which do you consider the best—the three or four speed transmission?

W. I.

Santa Ana, Cal.

Your questions are rather broad, yet we will attempt to answer them as well as possible.

Question 1. The slide valve there spoken of differs from the ordinary valve (which is not a slide valve at all) in that it slides. That is, the usual form of valve sets into a seat and thus covers a hole, being lifted to uncover this when it is necessary to admit or discharge anything through it. The slide valve, on the contrary, consists of a circular, hollow sleeve, which slides up and down continuously. In this there are cut a series of slots or ports, which at the proper time in the stroke cover or uncover other ports in the walls of the cylinder, thus affording a passage through the sleeve and cylinder to the outside. In this particular engine we do not know any more than you do what form of valve is used, but presume that it is of the rotary type, the action of which is similar to the slide valve, except that it rotates continuously instead of reciprocating. There is this difference between the two, however: the slide valve, just like any other valve which is moved up and down, must be driven at half of the crankshaft speed, while on the rotary valve other speeds may be used, according to the desired action of the engine. Thus one engine which was built with rotary valves had them rotate at one-fourth of the crankshaft speed.

Question 2. Although there is apparently much difference between the coiled spring clutch and the ordinary cone clutch, it simmers down on close investigation to the same thing. There is this minor change, however, that one uses a steel spring for a contact surface, and an interior cone as well as the usual exterior cone. The Renault type, on the other hand, uses a leather lining, or leather and cork. It would appear as if the use of the coil spring interposed between two cone surfaces would give double the clutching surface, and therefore could be used with a spring of half the usual strength. This would make declutching easier and more gentle.

Question 3. This question is too broad to be answered directly, but we can say that the two seldom conflict, one being used for one purpose and another for another. Thus all of the very highest powered cars, which might reasonably be described as those of highest speed as well, are fitted with four speeds. This is due to the fact that with such a large moving mass both a much slower speed than usual and a much higher ratio of gearing on the high speed are necessary. This makes it advisable to add one to the number of speeds in the gear box. On the other hand, the medium priced and more moderately powered car has no need for either very high or extremely slow speeds, for the class of people who purchase this kind of car, in doubtful cases, are not afraid to stop the engine. This dispenses with the necessity for so many speeds, and as a consequence the transmission is smaller, more compact and lighter in weight.

In the very few cases where moderate powered cars may be had with four speeds or high powered cars with but three, it is a matter of individual preference on the part of the constructor.

WANTS TO BUY TRACTORS

Editor THE AUTOMOBILE:

[2,003]—We are interested in gasoline tractors for pulling gang plows and doing other similar agricultural work, and although from time to time have seen cuts of such machines, do not know the addresses of any successful ones. If you have such addresses, we would be pleased to have you publish this information. H. & COMPANY.

Sumter, S. C.

Although we cannot give you a complete list of such makers, nor guarantee that any list given would include only the successful ones, we are appending a list which includes nearly all of the competitors at the recent agricultural machinery competition at Winnipeg, mentioned in detail elsewhere in this issue. In this list they are arranged in about the order in which this contest and others would place them as to merit:

Kinnard - Haines Company, Minneapolis, Minn.
Hart-Parr Company, Charles City, Ia.
International Harvester Company, Chicago.
J. I. Case Company, Racine, Wis.
Russell & Co., Massillon, O.
The Avery Company, Peoria, Ill.

HIGH TENSION VOLTAGE

Editor THE AUTOMOBILE:

[2,004]—Will you please let me know through "Letters Interesting and Instructive" approximately the voltage of a high tension current as used in modern jump spark ignition systems, both from an induction coil and batteries and high tension magneto. R. G. McCREIGHT.

Camden, S. C.

The voltage at the moment when the spark jumps may attain any figure between 10,000 and 15,000 volts, inclining somewhat more toward the lower than the higher figure. Porcelain walls of spark plugs will not withstand more than the upper figure, so it is very reasonable to keep below it. These figures apply equally well to the self-contained magneto system, that is, the magneto which is a complete system in itself, and to the battery and coil system, in which the current from the battery is stepped up in voltage by the coil.

AIR OR WATER, WHICH?

Editor THE AUTOMOBILE:

[2,005]—I would like to ask you, entirely as a matter of information, why it is there are so many water-cooled gas engines in automobiles and so few of them air-cooled. As I understand it, the most efficient temperature for economic gas combustion is acknowledged to be 350 degrees. Water cooling will not permit of this high temperature, and the thought presents itself that the use of expensive radiators, pumps, plumbing etc., creates a hazard in freezing weather, and adds cost, weight and complications simply to defeat the fundamental economies of that type of engine.

Am looking for general facts and not commercial argument. I know of air-cooled cars that have been in use for many years with great economy and perfect satisfaction. I know it is possible to make an air-cooled engine that will not heat up excessively when running either high or low gear and when touring or standing still. I believe these engines require very little more lubrication than other cars, and will only smoke when too much oil is used. If these facts are so why do the majority of cars use the unnecessary water system of cooling?

D. C. N. C.

New York City.

Your first statement that "the most efficient temperature * * * is acknowledged to be 350 degrees" is susceptible to proof; that is, this is *not* acknowledged—in fact, just recently, page 273, August 12 issue, there was published the tabular results of one accurate test, made by S. F. Edge, in England. Consulting this, you will discover that he found the most economical temperature, both as to power and fuel consumption, to be 149 degrees, both 186 and 212 degrees showing less power developed and more fuel used. This result was somewhat astonishing to the writer when first published, for his own experiments had led him to believe the most economical temperature to be about 200 degrees, or as close to the boiling point as it was possible to run the engine. Laying all this aside, the popular, or, to put it otherwise, the most general idea seems to be that the water-cooled motor offers more in the way of reliability. As indirect proof of this, it may be said that the estimate of the cars which will be produced during 1910 is 200,000. Of these, not over 10,000 (which is, incidentally, a very high estimate) will be air-cooled. This amounts to one-twentieth, or 5 per cent. Worded otherwise, 5 per cent. of the people who buy and run automobiles prefer air cooling, while the other 95 per cent. seem to prefer water. If one can judge fairly from the number of firms concerned in making the two kinds, the air cooler is on the decrease, for several concerns wedded to this construction have gone out of business in recent years, and more have turned to the other type. They doubtless were unchanged in their faith in the ability of air, but failed or changed for the reason that public preference made the other kind easier to sell.

ANSWERED AND DISCUSSED

GAS TURBINE INVENTION

Editor THE AUTOMOBILE:

[2,006]—The following are a few queries which I will be greatly obliged if you will reply to in your column "Letters Interesting, Answered and Discussed:"

I have recently worked out improvements in the two-cycle engine and gas turbine combined, and though I have come across nothing of the same nature, I cannot but think that I have been anticipated. Before going to the expense of having searches made, I would like to be able to look up recent development in this line, and would be glad to have you advise me where I can obtain either a concise account of recent improvements (including those in practical operation) or various articles bearing on the subject. That is, either a complete book or a series of separate articles.

I presume an application to the Commissioner of Patents for all existing patents would cost as much as a special search. Can you recommend the patent department of any paper, or any firm or party who make such searches at a reasonable charge?

TURBINE.

Half Way Tree P. O., Jamaica, B. W. I.

There is a book published on patents (it now comprises several volumes), these being restricted to those applicable to the automobile, either directly or indirectly, which might be of some use to you. The title is United States Automobile Patent Supplement, and it is published by some book firm in New York City. You might apply to the Class Journal Publishing Company, 231 West 39th street.

This does not contain anything of a practical nature; in fact, no book on patents does. It seems to be impossible to treat the two sides of invention—that is, the patent and the practical sides—at one and the same time. The fact of the matter is that a man fitted to pass on the patent side seldom knows or cares anything about the practical or operating side, and vice versa. There are no separate articles of this sort that we know of, either.

We never recommend any firm or private party in these columns. As to getting the patent papers direct from Washington, this is more simple and less expensive than you seem to think. The charge is but ten cents per paper, and the Patent Department sells stamps of this value, which may be bought in quantity, and used at leisure, one at a time or otherwise. The thing for you to do is to buy, say, $2 worth of these and send in for a list of subjects, which we believe is furnished free. Then select the likely subjects and send in stamps enough to cover the number which you wish to obtain. The Patent Office will not make a search for you, nor would it fill such a broad order as "all existing patent papers" on any one subject.

In case you go to a patent attorney you may judge whether he is charging you much or little by the amount which his fee exceeds the Government fees. The latter amount to $35 and are invariable. The attorney to whom you go will either make you a lump price for the whole job, in which case he pays all fees, or he will tell you what his services will cost, in addition to the Government fees.

Doubtless preceding letters on the same subject will be of interest, so a list of those which touch on this matter is given. In the issue of THE AUTOMOBILE for Feb. 4, 1909, will be found a letter entitled "Wants to Know If the Idea Can Be Patented," about patents, and taking out one. Then, in the May 27, 1909 issue, there was a letter headed "Gas Turbines," in which a contributor was given some idea of the existing types, with sections through two of them. Also, a brief mention of the literature on the subject. Lastly, in the June 24, 1909 issue, a letter under the caption "Gas Turbine Prospects," dealt with the matter of cooling the blades.

WAY TO CLEAN CYLINDERS

Editor THE AUTOMOBILE:

[2,007]—Many instructive questions and answers appear in your "Letters Interesting," and I wish a word with you. I have recently been experimenting in cleaning spark plugs, when very much sooted, by making a solution of concentrate lye and water, and let the plugs remain in it over night; the next morning the soot and carbon can be wiped off with a rag, and the metal part is about as clean as new.

The question arises, can this solution be used in cylinders to remove a coating of carbon; is there anything in it that will injure the iron? It certainly cuts out the carbon and softens the deposits on plugs.

C. W. W.

Delaware, Ohio.

Yes, this same solution could be used, but since the interior walls of the cylinder have a very smooth finish, obtained at much expense by the manufacturer, it would not be advisable to let the solution remain in there over night, as you do in the case of the spark plugs. A concentrated solution would probably attack the iron itself, besides destroying the finish, but a very weak solution would do little in the way of eating into the metal. The worst thing that would happen is that the water would rust the interior of the cylinders badly, and this would have to be removed before running the engine again, else you would be likely to lose pistons and rings, as well as cylinders, as against cylinders only. You have not asked for our advice, but if you had we would say do not use the solution.

A recent suggestion in the way of cleaning carbon from the cylinder walls may be appropriate here. This was to place in the suspected cylinder one of the soft wire chains used around the kitchen. With this in the cylinder, run the engine for a short time and the carbon will be broken loose.

WHY FAVOR TWO-CYCLE?

Editor THE AUTOMOBILE:

[2,008]—I have been watching the columns of "The Automobile" for years, hoping that you would eventually, though tardily, acknowledge the superiority of the two-cycle motor, as exemplified by the product of the Elmore factory. I speak of the Elmore because of nearly two years' experience with a three-cylinder 24-horsepower car, and I am in a position to know of the great efficiency of this engine.

No motor, whether it be two or four-cycle, scavenges completely, possibly a six-cycle might do so. There is always a small amount of burnt gas remaining in the cylinder, but this residue of the burnt charge does not dilute the fresh charge as stated in your answer to letter 1,986. The fresh charge and the burnt gases do not mix readily, and the small portion remaining in a two-cycle is not important except that it goes to disprove your statement that the two-cycle motor is wasteful of fuel, allowing it to escape with the exhaust.

The deflector on the piston turns the fresh charge toward the top of the cylinder, pushing the residue of the burnt gases ahead of it to the exhaust port.

As these fresh and burnt gases do not mix, and as there is a small amount of burnt charge remaining in the cylinder when the piston closes the exhaust port, it follows that none of the fresh gas has been wasted, as it could not pass through the residue of the exhaust lying against the exhaust port, and effectually blocking the passage until the same is closed by the rising piston.

Another point that makes for efficiency in the Elmore two-cycle is that the compression space is small, compact and perfectly tight. An Elmore motor does not lose compression after a year's service, the perfect lubrication takes care of that most effectually. An Elmore motor does not smoke, and you can test the perfection of the oiling system by holding your handkerchief at the end of the exhaust pipe, remove it and it will remain as clean and white as before the experiment.

Try this test on some of the four-cycle smoke motors on cars selling as high as $5,000, and note the (greasy) results.

The Elmore four-cylinder motor furnishes four light, smooth, power impulses per turn of the flywheel in ordinary driving on good roads; strike a heavy grade and open the throttle; four powerful impulses per revolution follow, but are applied so smoothly and quietly that it is very easy on machinery and tires; therefore, minimum repair expense.

Contrast this with the two heavy explosions per revolution in a high-powered four-cycle motor, there being an interval between each two-power impulses. The results tell on the tires, the mechanism of the car, and on the passengers. There is no interval between explosions on any Elmore motor, the power impulses overlapping each other and resulting in a smooth application of power more like an electric motor than the ordinary explosion engine.

In conclusion, if it is a fact, as you state, that the two-cycle motor is wasteful of fuel; that it will not develop over one-fifth more power than the same sized four-cycle engine, and that the "doubling up, or doing two things at once" is a hindrance to its perfect working, then please explain why I can take six full-grown people up a stiff grade in my 24-horsepower car that has been in service twenty-one months, and do this on high gear at a good rate of speed, when it bothers some of the so-called "thirties" to get up with four passengers? Also please explain why, in a distance of over 8,000 miles, my repair expense runs less than one dollar a month and why my total expense is less than ten dollars a month, and why the original set of tires are on the car in running order, three punctures being the extent of the trouble? Last, but not least, why do you suppose I was able to drive this car from November 25, 1907, until December 22, 1908, without ever entering a shop or making a single machinery repair? Would advise that you make a thorough test of a 1910 Elmore and then give the two-cycle motor its just dues, regardless of the fact that it is now greatly in the minority.

W. H. THAYER.

Pueblo, Cal.

A single question will suffice in answer to Mr. Thayer's argument above, and it is suggested by his own last sentence. If all that he says or claims is true, why is it that the two-cycle is "now (as always) greatly in the minority?" In comparing different engines double as many four-cycle cylinders should be used as two-cycle.

FINAL SKIDDING SOLUTION

Editor THE AUTOMOBILE:

[2,009]—I have read your reply to the Letter (1,994) of "I. B. G." I have also gone over your diagram very carefully, and still think that you are wrong. Let us suppose that a car is skidding on a wet pavement. If the driver holds his front wheels straight, that is, in the direction in which the car was going, the rear wheels will skid let us say to the right until the steering angle is reached. By the steering angle I mean the extreme angle which the front wheels will make with the line "A B." Now, when this limit is reached, the still skidding car will then begin to drag the front wheels around and will, of course, have to work against the resistance of these wheels on the roadway. If the front wheels had been turned to the opposite side when the skidding started, the resistance which you have marked with arrows against the front wheels does not operate against the skidding rear wheels but increases the angle made by the line "B D" with a line drawn through the hubs of the front wheels and practically gets the front wheels out of the way. The result is that the limit of the angle which I have called above the "steering angle" cannot be reached, and therefore the car will keep on going around as long as there is momentum enough to carry it. On the other hand, if the front wheels are quickly turned in the same direction as the skidding rear wheels, the steering angle is quickly reached and the momentum has to work against the resistance of the front wheels through a greater distance. For this reason the skidding car will hardly, if ever, turn completely around if the wheels are turned in the same direction as the rear ones, while if turned in the opposite direction, with fair momentum, the car will surely face about. I trust that I have made myself clear in writing about this matter as, in practical use, I have saved myself from the gutters many times here in New Orleans where we have deep ditches on either side of the roadway. When driving through the city streets where the roads have a fairly high crown, and one has to keep to the gutter side, and where the street department's water cart drivers go to sleep and deluge the pavements, making them more than slippery, because they do not wet enough to wash off the dust but only convert it into mud, a driver is very apt to feel his rear wheels slipping toward the ditch. As sure as death and taxes, if he faces his front wheels in the opposite direction to his slipping rear ones, he will need a friend to get him out, whereas a quick turn in the same direction, and then when he feels the resistance of the rear wheels against the front ones, turn them as quickly to the straight line again, will keep him "a-going" along just as if nothing had happened. ALBERT J. MAYER.

New Orleans, La.

While not agreeing with the writer above, nothing will be offered to dispute him, since we do not wish to prolong the already lengthy discussion of this subject.

STOP THAT MISSING

Editor THE AUTOMOBILE:

[2,010]—I drive a six-cylinder car, with which I am having much trouble. As long as the motor runs rapidly, either on the high speed or any other speed, it pulls well, but it both misses and backfires when running slowly. The trouble is no doubt in the carbureter, because when running on either storage batteries or magneto, or both, it does the same thing. The valves are all right as to time, and all cylinders have good compression. Aside from the source of trouble, the carbureter is all right, too, as I have had the float out, dried it, and given it an extra coat of shellac. W. K. RODGERS.

Brilliant, Ohio.

Your trouble lies in the adjustment of the carbureter, rather than in the carbureter itself, and from the description of your trouble it looks as if you were feeding the engine too lean a mixture. This may be done by having too much air or too little gasoline. To adjust the carbureter properly it should be adjusted not for high speed alone, but for slow speed as well. This is done about as follows: Run the engine as slowly as possible, gradually reducing the gasoline until you have brought this down as low as the engine will stand and still continue to run. Then try this out on the road and find out if you have gone too low or not low enough, remembering that the lower you go at this end, the less will be your fuel consumption. Having satisfied yourself as to this slow speed adjustment, take up the high speed, which usually consists of the auxiliary air only, since the motor usually can suck enough gasoline for any speed. Run your engine as fast as possible, meanwhile slowly, very slowly, opening the auxiliary air valve adjustment, as long as the speed continues to increase. Try this several times, until you obtain the widest possible opening, or, rather, that opening which gives the highest possible speed. Then try it on the road, as was the case with the slow speed adjustment. This latter step is always advisable, since, after all, it is for road use that you want it adjusted, and the two vary greatly.

RULE OF THE ROAD

Editor THE AUTOMOBILE:

[2,011]—I have noted in your issue of May 27, 1909, an article headed "Aids in the Driving of a Car, Part 2." In this there is something about passing cars or other vehicles on the wrong side, illustrated by means of a figure, showing a car passing on the inside of a truck.

In your illustration you speak of car A taking the course A, which I suppose is the lower line, passing the truck on the wrong side. Our Michigan law in Section 17, Act 196, 1905, would give us exactly the opposite interpretation, if I understand it correctly.

Am I to understand from your article that the truck, or the first vehicle on the road, has the right of way over the second vehicle or automobile, and that the truck would naturally turn to the right in passing another vehicle and thereby leave little room for the second vehicle, or auto, to pass on the right side, therefore making it necessary, and the natural course for the vehicle No. 2, to receive little consideration and be compelled to pass on the left hand side?

Traverse City, Mich. LEON F. TITUS.

You are right about the law, which requires the second vehicle or automobile in this case to take the left hand or upper course, as indicated by the dotted line. This would make the truck turn in to the curb and give the automobile more room to pass, or if it did not do so, the machine would be obliged to slow down, and drop back behind the truck until the other approaching automobile had passed.

If you will reread the article which goes with this figure, however, you will find that the writer advocates that automobilists neglect to observe the letter of the law, since the average truck driver will do likewise and not turn out from its central position. It is there pointed out that the usual country road is highly crowned or cambered, and that for this reason the truck driver will not turn out, as that would mean much difficulty in getting back.

It is also there pointed out that to take the right or legal course presents more danger than the one advocated, since the truck driver will not turn away from his central position, and the automobilist passing at speed, will find himself running head on into the other approaching machine, with much danger to both.

FLYWHEEL WEIGHTS

Editor THE AUTOMOBILE:

[2,012]—Will you please give me a formula for proportioning the size and weight of flywheels on large stationary gas engines, one that could be used for any type or size of engine. HARRY DAY.

Buffalo, N. Y.

The very idea of a flywheel, to steady the running of the engine by storing up energy during the power stroke and giving it out again during the idle strokes, shows that the weight is the necessary item, the size usually being a matter of conveniently arranging that weight.

Mathot is responsible for the following formula:

$$P = K \frac{N}{D^2an^3}$$

from which the total weight equals 1.4 P. In this formula, P = the weight of the rim alone, without arms, spokes or bosses.

D = the diameter of the center of gravity of the rim in meters.

a = the coefficient of irregularity.

n = revolutions per minute.

N = brake horsepower at that speed.

K = a varying coefficient, this varying with the type of engine, cycle, and number of cylinders, as follows:

44,000 for four-cycle, single-cylinder single-acting.

28,000 for four-cycle, two opposed cylinders, single-acting, or one cylinder, double acting.

25,000 for two single-acting cylinders with cranks at 90 degrees.

7,000 for four twin opposed or two tandem double-acting cylinders.

In use, the service determines the co efficient a, as, for instance, electric lightin service would require a very low coefficier of irregularity, such as 2 per cent., or .o Then n and N would be assumed, the as sumption of the type and cycle fixes th varying coefficient K, from all of whic P and D would be found by the method c trial and error. That is, a diameter is a sumed and the figures carried through. the result is not correct nor satisfacto make another assumption, either higher lower, as the former result was too low too high, and carry through another seri of figures.

The only arbitrary part of this is the c efficient, which was determined by caref experiment from a number of Continent engines, most of them from Germany a Belgium. The coefficients as given are ve reliable.

None of the above applies to automob construction, and students of the latter, terested in the subject of flywheels but having the time to work these out from correct mechanical standpoint, may use following for which Güldner, the Germ scientist, is responsible:

$$R_{\varepsilon} = C\,(.75 + \xi)$$

Lucke on page 242 of his work on Engine Design, gives a table of values the two constants.

Appearance of Mora Light Four Touring Car, Upon Which Factory and Other Facilities Will Be Concentrated

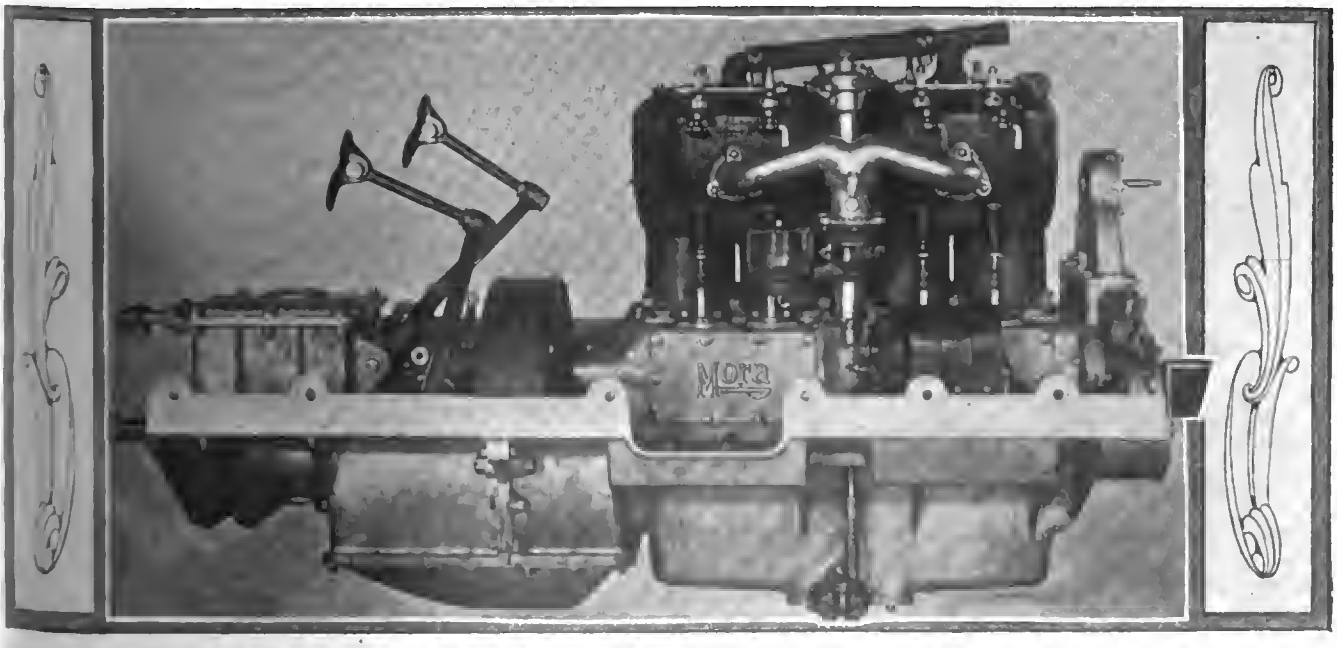
AT a time when everybody is talking of "sixes" and long stroke motors, the plans of the engineers for the Mora Motor Car Company, Newark, N. Y., relative to the season of 1910 may prove to be epochal in their character, since this company will abandon the "six," devoting its whole energy to a single type of four-cylinder chassis in which the length of the stroke of the motor relative to the size of the bore has been reduced. Moreover, added zest is lent to this announcement, by the statement that the price of the four, which is continued for 1910, will be slightly increased.

Some small but consequential changes have been made, including a longer wheelbase, larger wheels and tires, a new carbureter, gear pump for the oiling system, change in the water pump from gear to centrifugal, "tee" instead of "ell" head motor, placing the valves on opposite sides instead of all on the left side as before, gear drive for the fan, and many other little refinements.

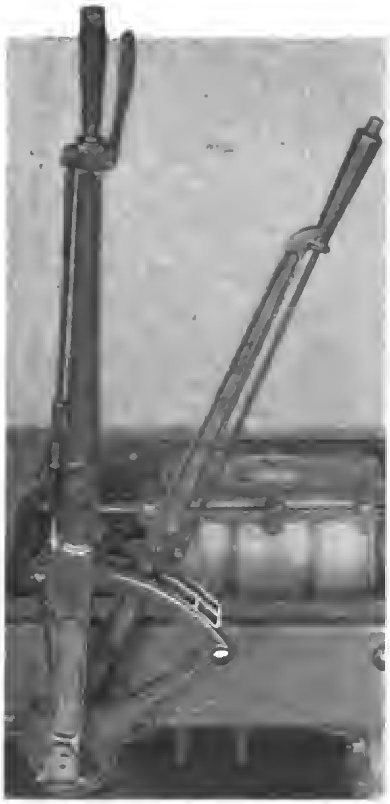
This model, which the Mora people do not call by a model number, although it is the fifth which the company has produced, will continue to be known as the Light Four. Of this title, the first word is descriptive of the light weight construction, which this concern advocates, and the second, of the number of cylinders of the engine. In the continuation of this model, five important points, which might even be called policies, have been kept constantly in the foreground. These are: first to refine continually a car of a given type, and thus obtain the advantage of previous use on the part of many users; second, to build every piece in the factory, so as to be able to supervise its construction; third, to build a car of intermediate weight so as to keep down tire and maintenance costs; fourth, to design and build for reliability at all times; fifth, to design and build as simply as possible, omitting all unnecessary parts.

Adherence to these points has resulted in the production of the Light Four. This is powered with a four-cylinder engine of 4 1-2-inch bore by 5 1-8-inch stroke, as compared with the previous motor, which was of 4-inch bore and the same, 5 1-8-inch stroke. Just as the old engine was conservatively rated at 25 horsepower, so the later one is also given a modest power rating of 38. The change in the bore alters the relation of bore to stroke, which in the light of the present foreign tendency is perhaps worthy of further mention.

The former bore and stroke gave a ratio of 1 to 1.28, one of the longest ratios to be found on an American car. The present



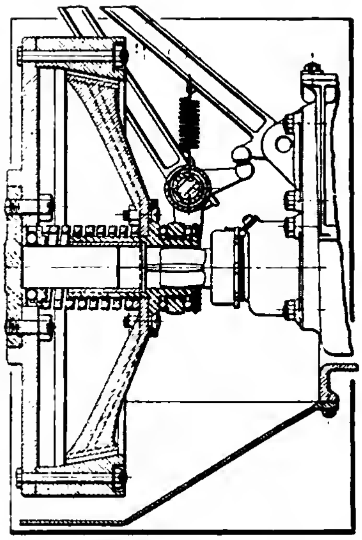
Clean-Looking Inlet Side of the Unit Power Plant, Showing New Cylinder Construction, Carbureter and Magneto



Mora Control Levers and Quadrant

sizes make this read 1 to 1.14. This latter figure, strange to relate, agrees exactly with the average of 78 different engines exhibited at the two New York automobile shows of last winter. Most noticeable among the many changes in the engine is the alteration in the cylinders, which are now cast in pairs with the valves on opposite sides. This construction makes the cylinder castings symmetrical, and, therefore, balanced in weight better. The exhaust is placed on the left, with the water pump, while the right side carries the inlet, carbureter, and magneto. This distribution of the accessories sizes the gears so that the gear cover, of aluminum, at the front of the engine case, becomes symmetrical about the center line. The upper part of this is now carried up to take in the new gear drive for the fan, this being effected through spur gears, which replace the former leather belt drive. The cover is so designed that it is possible to remove the fan drive for adjustment or other purposes, without disturbing anything else. The valves, which are of two metals, nickel steel heads welded to carbon steel stems, are of large diameter and liberally water-jacketed. Unusual care has been taken with the camshaft so as to preclude the possibility of acccident. Thus, the case hardened cams are both keyed and pinned to the shaft. Should the pins fail, the keys will still hold them in place, and are made of sufficient size to do the work.

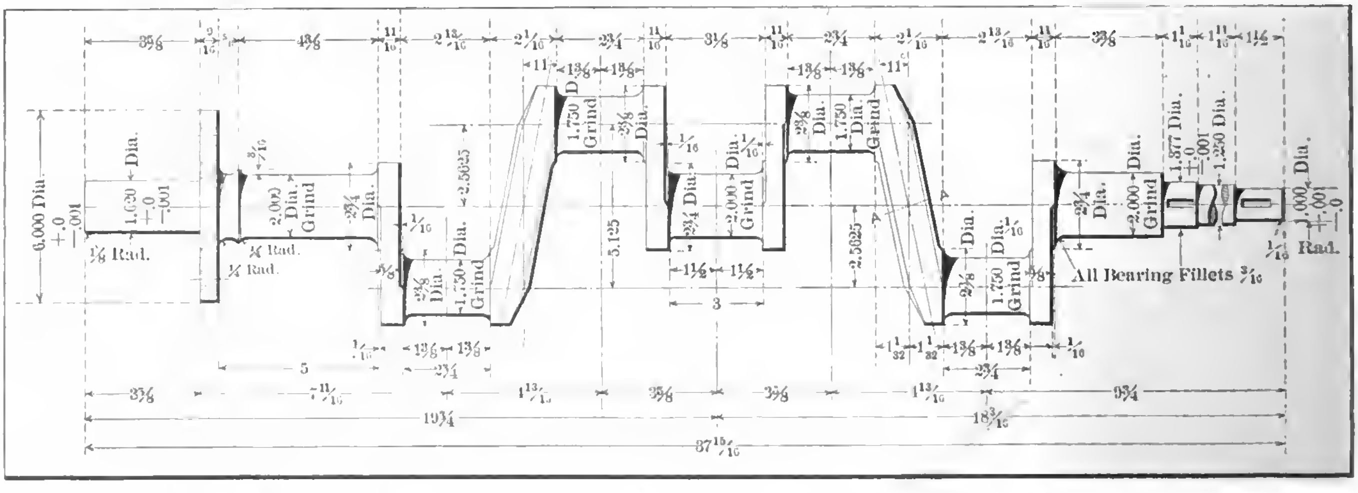
Combination Crankcase and Mud Pan—One of the principal features is the cast aluminum crankcase and mud pan combined. While this is an expensive construction, the builders consider it as superior to such an extent that it is made the feature of the car. This pan gives the power plant great rigidity, being bolted securely to the transmission case, and thereby eliminates the universal joint between engine, or rather, clutch, and transmission. This pan really makes the frame more stiff, while the close connection with the frame makes the crankcase a more rigid form than it would be otherwise. In other words, each one mutually stiffens and strengthens the other. This, too, with a liberal use of aluminum, which is famous for its light weight. This free use of aluminum is noticeable throughout the chassis, despite the high market price of the light-weight white metal.



Inverted Cone Clutch Is Self-Contained as to Thrust

Coincident with the increase in the size and power of the motor, the crankshaft has been increased both in diameter and length of bearings, as shown by the appended reproduction of the working drawing. The shaft is heavier and the bearings longer than general practice would make them, which is an excellent point in their favor. The makers say that a few extra pounds weight here is metal well placed, and have as proof that they are right the records to prove that no Mora owner has ever had a crankshaft break. The bearings are of parson's white bronze, a very superior bearing metal, which has a high heat resisting quality, combined with great hardness, yet will melt and save the crankpins from damage before it will seize. This feature is worthy of consideration, since the bearings are made interchangeable and it is but a moment's job to replace one or more of them, and the expense is also small. To buy and replace a crankshaft, on the other hand, is a very complicated, tedious, and expensive piece of work, and onc that a novice would tackle with fear and trembling. So it is better to have a bearing that will melt in the absence of lubricant.

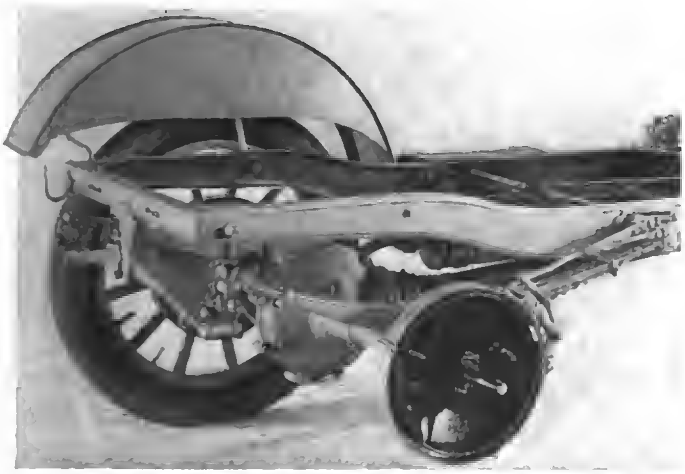
A leather-faced, inverted cone-clutch acts as the transmitter of the engine power, and is placed within the flywheel. The clutch spider is of aluminum and strongly ribbed. This is bolted to a steel sleeve, the inner end of which is bushed for the end of the crankshaft. The construction of the interior of the clutch is such as to leave it free from thrust when engaged. The square section clutch spring presses against a large ball thrust bearing. The clutch operating fork is in addition placed between a pair of ball thrusts. This fork is operated from the foot pedal, this having adjustable foot pads, by means of a short, hardened end, pivoted on a crossshaft. The flywheel clutch sur-



Crankshaft Drawing with Complete Dimensions Will Be of Much Interest to Other Designers as a Worthy Example face is bolted up to the forward disc by six bolts, the nuts being set into a series of counterbores, so that they are inside and do not project to catch in the clothing when making an adjustment.

Excellent Oiling System for Engine—Improvement being the order of the day, the engine oiling system has been improved. As it is at present, the oil is circulated by a small gear driven pump, located on the outside of the crankcase, inlet side, and on the lower part so as to be accessible at all times. This is supplied with oil from a false bottom in the crankcase, and cast integral with the lower part of it. From the reservoir, the oil is pumped to another smaller header attached to the inside of the hood. Thence it flows by gravity to the crankshaft bearings and cylinders through copper pipes, a sight feed indicating the amount of the flow and its regularity. The overflow from bearings and cylinders drops to the bottom of the case, where it is maintained at a constant level, and used as the source of oil for an interior splash system. The surplus oil, over and above that needed for the splash system, drains back into the crankcase reservoir, and is thus used over and over again.

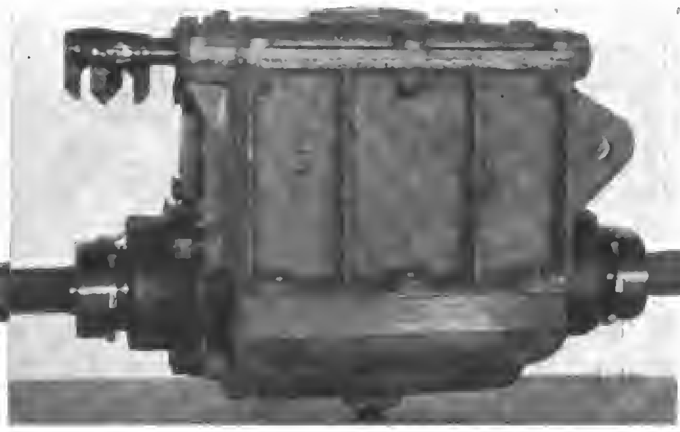
Successful Transmission of Last Year Continued—Like the clutch, the transmission is unchanged, that of last year, which was unusually successful, being continued. This affords three speeds and reverse, operated selectively. All shafts are mounted upon ball bearings. Large diameter shafts, large faced gears of large pitch, and other items making for an unusual factor of safety in the gear box just as in the engine, characterizes this speed reducing means, which already possesses the proud record of over 400 in steady use for a year, without a repair or replacement. As built, it is a complete and self-contained unit, which at the first sign of trouble may be removed bodily and another substituted for it, or at least, the trouble remedied outside of the car, with plenty of elbow room. Back of the transmission is placed the universal joint, this being of the company's own make and different. It is also famous for its simplicity, being but a squared shaft working in a squared hole.



Rear Spring Suspension and Brakes Show Ability

What the Axles Show—Flexible roller bearings of the Hyatt type carry the semi-floating bevel driven rear axle. The gears of the bevel drive are cut with unusual care, being of the now popular stub tooth form, which possesses more than ordinary strength. Front axles depend upon ball bearings to carry their load without friction. These are of very large diameters, 1 3-4 and 1 inch sizes being used. This axle is an I-beam section, drop forged in one piece with integral spring seats. As designed for a car of several hundreds of pounds more weight than the Mora, the same large factor of safety is always present.

To facilitate starting, the crank has been brought forward away from the radiator. It is now securely braced from each side. This radiator is just as it was last year, of the popular vertical tube type, of unchanged design.



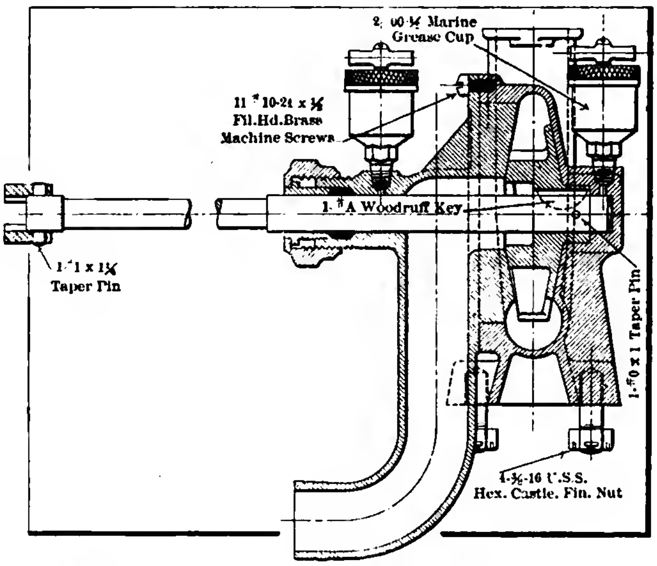
Complete Transmission Unit Removed from the Car

After some years of hard use, no flaws have developed in the spring suspension. The front springs are flat, semi-elliptic, and the rears, three-quarter, or as they are more commonly called, platform springs. The front springs are purposely made rather stiff, the good riding qualities being obtained from the rear spring suspension. To aid in this the body is placed rather far forward, and the space back of it allows plenty of room for a trunk rack, large enough to accommodate a real trunk.

The wheelbase has been increased to 112 inches, the additional 2 inches over last year affording more comfortable riding, also more leg room in the tonneau. Working toward the same end are the larger wheels and tires, the former now having a size of 34 inches, while the tires are 4 inch all around. The wheels are of the artillery type, with 10 spokes in front and 12 in the rear wheels.

Two complete sets of brakes are used, one internal and the other external. These operate on the rear wheel brake drums, which have been increased in size, so that they now measure 14 inch by 2 inch. Not only are they unusually efficient, but their ease and equality of operation is facilitated by the use of a compensating brake bar. This contributes equal pull on all brakes regardless of the amount of power applied or the adjustment, and insures against skidding, through having one wheel held more than another.

The bodies are another example of the great care used in the construction of these cars. They are built with sheet metal panels, the mouldings of which are rolled in the metal and not riveted on. This results in a dependable body, which can be relied upon not to crack open at the seams under the first hard usage.



Cross-Section Through Centrifugal Type of Water Pump

The Leader of the Holsman Line, a Serviceable Runabout for Rough Roads

DESERVEDLY popular in the West because of its ability on rough, sandy or hilly roads, the Holsman high-wheeler is now entering upon its ninth successful year. During this period it has undergone fewer important changes of design than perhaps any other car which has been before the public for an equal length of time. The Holsman Automobile Company, of Chicago, the maker, has always remained true to the principle of high wheels—for, as it says, "high wheels travel all roads, because all roads are made to be traveled by high wheels." The wisdom of this epigram has been demonstrated by the steadily increasing average size of automobile wheels, even when shod with pneumatic tires, which seems to indicate that other manufacturers are slowly coming around to the same point of view. The Holsman, however, does not rely on this single feature to distinguish it from the conventional type; its gear-changing, if such it can be called, its method of securing differential action of the driving wheels, and by no means the least, its four-cylinder design of motor, are any one of them sufficient to challenge the attention.

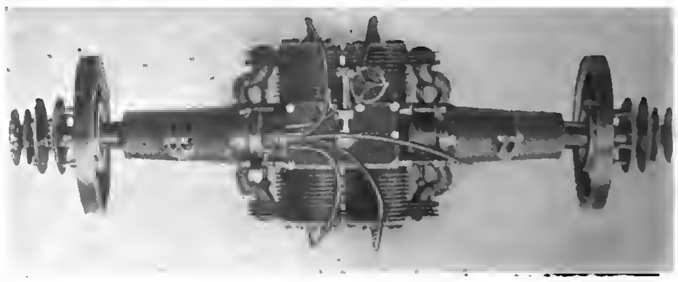
Belt, Chain and Friction Drives Combined—The Holsman method of driving the rear wheels will certainly be distasteful to the man who likes to classify every detail in its proper pigeon-hole. The Holsman drive refuses to be classified, at least according to any ordinary standards. It is a combination of belts, chains and friction rollers, each performing a definite purpose. The ingenuity of the construction will be perceived when it is explained that the gear-changing, which gives two speeds forward and one reverse, is all obtained through varying the method of drive. When the belts are in action, the car is on high gear; the chains give the low gear, and the friction rollers the reverse.

Complicated as this may seem at first glance, the construction is startlingly simple. In fact, at a casual glance there appears to be no change-speed mechanism at all. One sees the motor, placed under the body of the vehicle with its shaft extending from side to side, small pulleys on the ends of the shaft, and belts which pass around larger pulleys on the rear wheels. It takes a close examination to reveal the trick. The belts are really chains, although their action on the high gear is that of belts. When starting the car, or on an unusually steep hill, the two flanges of the grooved pulley spread apart, revealing a sprocket between them; the belt, now become a chain, drops in, its rollers engage with the teeth of the sprocket, and the car is chain-driven. The chains, however, still remain belts as far as the pulleys on the rear wheels are concerned. As the sprockets are considerably smaller than the pulleys they replace, this drive gives a greater gear reduction, and the car is then on low speed. It will be evident, however, that unless some special provision were made the chains would be very loose on the low gear, and would be apt to jump occasionally. The necessary provision is again obtained in the simplest, though most unexpected way; the whole motor, with its shaft, pulleys and sprockets, is hung from the frame by two knuckle joints, on which it may be swung backward and forward. A forward movement of the motor, therefore, obtained at the same time and by the same action of the controlling lever which spreads the pulleys apart to disclose the sprockets, tightens up the chains and forces them into firm engagement with the sprocket teeth.

This flexibly-supported and moveable motor once conceived, its second application became immediately apparent. The ends of the motor shaft were extended beyond the pulley-sprockets, and a second set of grooved pulleys applied. Swinging the motor backward then brings these pulleys into direct contact with the solid rubber tires on the rear wheels, and provides the reverse. The same action loosens the chain-belts so that they no longer exert any driving effort forward, although they remain in place. By an ingenious system of connections, these various movements are obtained by progressive movements of a single lever. This lever swings horizontally on the top of a shaft which is united with the steering column, making it extremely convenient to operate.

Two Speeds and Reverse without Gears—To summarise, then: the motor is started and runs idly hanging in its middle position, neither forward or back, and with the pulley-sockets spread apart. To start the car forward on the low gear, the motor is swung forward; this tightens the belt chains so that their rollers engage with the sprockets, giving a positive drive which will not slip no matter how great the load. To go into the high gear, the motor is swung back to its first, central, position, loosening the chains; then the halves of the pulleys are forced together, lifting the chains off the sprockets and converting them into belts. To obtain the reverse, the motor is brought to central position, the pulleys are spread apart to loosen the belts, and then the motor is swung backward till the small pulleys on the extreme ends of the motor shaft engage with the tires of the rear wheels. This drive of course rotates the wheels in the reverse direction to that obtained by the chain or belts.

The driving chains are specially constructed of hardened chrome-nickel steel. They run in deep sheaves, so that they can not be thrown out of engagement. On high gear the chains are as noiseless as an ordinary belt, and on the low gear make no more noise than the usual drive chain. The chains leave the rear sheaves at a point 15 inches above the ground, so that there is no danger of their becoming entangled with stones or brush. One of the particular advantages of this construction is that the power is applied as near as possible to the rims of the wheels; the spokes and hubs therefore do not transmit any power, but simply sustain the weight of the car, and can be made much lighter than usual. The wheels are 40-inch front and 42-inch



Unit Power Plant—the Motor and Change-Gear rear, and are shod with 1 1-4 inch solid rubber tires. Sweet patent wheels, with concealed metal band hubs and offset spokes, are used on the runabout, surrey and coupe, and Sarven patent wheels on the $550 light runabout and on the delivery wagons. All hubs are roller bearing except those of the light runabout.

How the Differential Is Abolished—So far, the reader will observe, no provision has been made for the introduction of a differential gear. The driving pulleys and sprockets are mounted directly on the ends of the solid, one-piece motor shaft. However, the same mechanism that is used to obtain the gear-changes provides a very acceptable substitute for a differential; in fact, the Holsman Company claims that in this case the substitute is better than the original. The trick lies in the movable suspension of the motor, which is interconnected with the steering gear in such a way that when the vehicle rounds a curve the inner end of the motor is swung back a little, loosening the belt on that side so that it can slip, while the belt on the other side is slightly tightened. The advantages claimed for this construction are not only its simplicity, but also a mechanical superiority, in that the amount of power applied to the wheels, as well as their speed, is varied. The ordinary differential gear, while allowing one wheel to run faster than the other, still gives the same power to each. On the Holsman, however, the inner wheel not only runs slower, but as its belt is slipping it receives less power, and the outer wheel, which is doing more work, receives proportionately more power. For this reason, it is said, the Holsman is little given to skidding.

Although the Holsman Company has experimented with wheel steering, it still retains the lever for use on its vehicles as being more reliable and easily operated. The lever connections do not wear or develop the lost motion which frequently becomes so noticeable in wheel-steering gears. There is no necessity for irreversibility or for great leverage; the nearness of the steering knuckles to the hubs, the narrowness of the tires, and the lightness of the front construction—hardly more than the weight of the front wheels themselves—are all conducive to easy steering. The steering post is placed in the middle, about eight inches forward of the seat, and carries also the other control levers. All are so arranged that they can be operated equally well from either the right or left side. In carrying out this same idea, the motor is so arranged that the starting crank can be applied to either side.

Four-Cylinder Motor Light and Compact—The four-cylinder motor, which is interchangeable with the two-cylinder motor on all the models except the light runabout, is, in its way, as radical a change from ordinary constructions as the change-gear. The cylinders are horizontal and are opposed in pairs. All piston pins and connecting rods have been abolished. The pistons of each opposite pair are rigidly connected by a steel frame straddling the crankshaft, following the design technically known as the "Scotch yoke." The yoke carries in its middle a large roller bearing, of which the inner radius is equal to the radius of the crank plus the radius of the crankpin. As the yoke, with its pistons one on each end, oscillates backward and forward, it rolls the crankpin around the inner surface of this bearing and so rotates the crankshaft. This design naturally limits the pistons to a very short stroke, but has compensating advantages in the way of eliminating numerous parts and bearings. Counting the three crankshaft ball-bearings, it will be seen that the entire motor has but five bearings, instead of the eleven which would ordinarily be used for the same work. The bearings are exceptionally large in proportion to the service which they perform.

The "unit power plant" idea is carried to its highest development in the Holsman. The motor crankshaft is extended at each end to carry the driving sprockets and pulleys. The crankcase is also extended in the shape of sleeves, carrying the lugs by which the motor is suspended from the frame, and supporting the shafts in large roller bearings. There are two flywheels, placed one at each end just inside of the pulleys.

Other features of the motor are so plentiful that they can

Holsman Surrey, a Car for the Whole Family

hardly be more than enumerated. The cylinders are air-cooled by flanges cast integral, and no fans are found necessary. The inlet valves are automatic and are located in the pistons; the mixture reaches them through the crankcase, much as in a two-cycle motor. The carbureter, a Holsman design with but one adjustment, bolts directly on to the top of the crankcase. The exhaust valves are actuated directly from the crankshaft, and the crankcase extensions carrying the outboard bearings of the shaft are used as mufflers. Lubricating oil is carried through the motor and into the cylinders with the gasoline mixture. No adjustments are necessary. Ignition is by batteries, with a single coil and high-tension distributor.

Holsmans Made in Many Types—Eight different styles of bodies may be had—three runabouts, a surrey, a coupe, and three delivery wagons. Three different chassis are built, with wheel bases of 65, 80 and 92 inches, respectively; on all of these except the smallest, the four-cylinder motor described above, which is rated at 26 horsepower, is interchangeable with a two-cylinder, 12-horsepower motor. This latter is of more orthodox design; its cylinders, 4 by 4 inches, are horizontal, opposed, and air cooled, but it has the usual connecting rods with plain bearings; its inlet valves are automatic and directly over the exhaust valves. It is adapted to the same unit construction as the four-cylinder motor. The $550 light runabout, with 65-inch wheel base and the 12-horsepower motor, is practically the same car that the Holsman Company has been building for five years, and a great number of them are in active service. All Holsman types can be had with a 61-inch tread.

Holsman Coupe, Especially Favored by Doctors

WIRE WHEELS SHOW PROGRESS

Modern automobilists, who are deeply interested in the subject of weight, and its immediate effect upon such items as tire mileage, repairs and per-mile-cost, will doubtless peruse the timely article elsewhere in this issue on the subject of wire wheels with more than ordinary attention. Many experienced motorists favor light-weight construction, but when this is applied to the subject of wheels, they sidestep, with vague and noncommital remarks about side strength.

The old superstition relative to this subject was that the wire wheel had much strength other than that necessary to sustain sidewise application of force. This has persisted and persisted until it might be said with truth that it has been the only formidable barrier to the popular adoption of this type of wheel. In fact, so deeply is this grounded that it is to be found in many books, one widely circulated work commenting as follows:

"Now while it is widely conceded that a wire wheel will sustain a greater load than a wood wheel, the two being considered weight for weight, it certainly will not sustain as great a strain sideways, which represents the line of the wheel's greatest weakness. A wire wheel driven against a curb with sufficient force will have its rim dented, with the result of loosening all of its spokes and ruining it. A wooden wheel, on the other hand, may have a gap in it and still be serviceable. It may even run with several spokes broken off," etc.

As dispelling in an effective manner this twenty-year-old superstition, attention is again called to the article mentioned above. In this there is a brief but convincing description of tests made on such wheels in England, in the course of which tests, wood wheels of the usual artillery pattern were tested under parallel conditions. The results show plainly why these wheels are so extensively used in England, since the old idea of lack of side strength is not only dispelled but unbiased tests prove that the opposite of this is actually the case, the wire wheel possessing a superior strength to its artillery competitor.

Second to nothing else in showing this is the accompanying series of tests, in which, having already put one of the artillery wheels out of business, the wire wheels surpassed the remaining wooden competitor by a tremendous margin. This test was in the nature of a reverse stress. Now, it is well known in engineering that the most severe stresses, and those which are most destructive, are alternations of stresses: applications of force from two opposite directions. Yet, it was under that very kind that the wire wheels stood up best. So it may fairly be said that a slight revision of our ideas relative to wheels is very much in order.

Viewed from a purely utilitarian standpoint, it means that the devotees of long touring can carry a complete spare wheel with tire, at the same total weight for the five wheels and tires, in case wire wheels are used, as the ordinary motorist with but four wheels and tires (those on the four wheels) of the wooden artillery type. That is to say, the weight of one whole wheel and tire is saved by the use of wire-spoked wheels.

ELECTRIC AUTOMOBILE LIGHTS

Ever since automobiles were invented their owners have been accustomed to struggle with refractory lamps. They have had tail lamps that would not stay lit; side lamps that smoked; headlights with clogging burners and cracking or tarnishing reflectors; generators which would not generate, and gas-tanks which refused to surrender any part of their precious contents. These annoyances are decidedly less frequent now than a few years ago; but the automobilist, accustomed to bestowing considerable care on his lighting equipment, still patiently stops his car at nightfall, dismounts, and trudges from lamp to lamp, kindling each one with a match carefully sheltered from wandering breezes. When he reaches home, on the contrary, he snaps a convenient switch, and instantly the room is flooded with light. Strange that the most modern means of travel should hold to so antiquated a system of illumination!

Electricity was formerly in ill repute for automobile lighting, as the incandescent bulbs of some years ago consumed an excessive amount of current, and at the same time were very susceptible to vibration. The carbon filaments were provokingly brittle, and with the filament once broken the lamp was worthless. Both these old objections have been nullified by the introduction of the tungsten lamp, which is at once economical of current and, in its improved forms, exceedingly robust. The smaller consumption of these lamps makes it practical, in some cases, to use ignition storage batteries as a source of current; a storage battery specially designed for lighting purposes will give perfect service, with very low cost. In addition, there are a number of mechanical generators which can be used both for ignition and lighting; the first cost of these is but little more than the battery, and they consume but an inappreciable amount of the power.

INDIANAPOLIS SPEEDWAY WILL HAVE A NEW SURFACE

INDIANAPOLIS, Sept. 6—Either the finest road brick or a bitulithic cement will soon be placed on the Motor Speedway and will give it the greatest track for automobiles in the world. This has been decided upon by the management, and for the last few days experts have been submitting figures and samples of materials that would be best for the complete roadway. A sum of $150,000 has been set aside for the purpose of resurfacing the course, and it is probable that still more will be necessary before the work is completed. It has been found that a bitulithic surface, would cost $100,000 and make the track smooth and hard enough to permit a speed of two miles a minute with safety. A layer of the very finest road brick, at the rate of $15 per thousand, would perhaps make the track even faster and certainly as durable, but the cost would be proportionally increased. The requirements would take 4,000,000 brick, costing $150,000, with $20,000 for laying them, meaning that the expense would be nearer $200,000 than $150,000. Money, however, is a minor consideration and whatever promises to give the greatest satisfaction will be adopted.

The officials of the speedway are determined to make the circuit all that was expected of it in the fondest hopes, and the entire equipment is being considered thoroughly to see where it can be improved. Experimental surfaces of brick and cement will perhaps be tried, but it is the opinion that the former will be the one selected. The cost of the entire affair to date is $425,000, and the added appropriations will raise this to nearly $650,000. In addition to the new surface for the racing machines there will be marked improvements around the grandstands. New restaurants will be installed in both the 50-cent and dollar parking fields, in addition to the two already there, and four refreshment stands will be built. Two tunnels will go under the track so that automobiles can be driven to the infield during the running of the events, or leave before they are entirely finished, at the will of the owners. There is room for 20,000 machines in these big parking spaces, and accommodation for others outside.

For the information of those watching the races the Warner automatic timer will be improved and enlarged so that in addition to scoring the number of the first three cars, the laps, and the time total, it will give the number of the events, the number of each race, and the complete score of every contestant. Assistant announcers will be stationed at vantage points and will receive their instructions direct from the chief announcer at the main post. The military board is training the soldiers so that the course will be policed better than ever at succeeding meets. The spectators will be assured of ample protection.

According to present plans it is the intention to hold the next automobile contests after the big aeroplane carnival, which will come during the middle of October. In this way the public will be given a chance to inspect the track with its new surface and will be positively assured that the accidents of the opening days will not be repeated. That series of events taught many lessons which are being carried out now. The management is in close touch with the needs of the big motordrome and the suggestions of those who witnessed the speed carnival last month have been given close attention. It had been announced that the next race meet would be held about the middle of October, but this has been postponed until later in that month, or until early in November. This will give the new surface ample time to set and make it safer. Then, too, there were conflicting dates which required rearrangement. A 24-hour race will be the feature of the next series.

Entry blanks have already been sent out for the proposed aviation contests, which are scheduled for October 15, 16, and 17. Aeroplanes, dirigibles, and balloons are included separately, but the conditions for them have not been announced. Cash prizes amounting to $10,000 will be offered. In a cablegram received from Glenn Curtiss he finally agrees to the terms offered him to be present with his biplane, and to attempt to better his record-breaking achievement at Rheims. He also gives the interesting information that a pupil of Louis Bleriot, with a Bleriot monoplane, will accompany him to the United States. It is expected that Curtiss and the Wright brothers will represent this country. Two dirigibles are being constructed here for the contests in their classes, one to be piloted by Carl G. Fisher and the other by G. L. Brumbaugh. Thomas Baldwin has assured the management that he will enter.

MUNSEY TOUR WILL TEST 1910 RULES

WASHINGTON, D. C., Sept. 6—Considerable interest attaches to the fact that the Frank A. Munsey reliability contest, from Washington to Boston and return, September 21-29, will be run under the 1910 rules recently adopted by the American Automobile Association. They will have their first tryout in this contest. Under these rules a fixed penalization schedule will be used, a fact that has been strongly commended by all the factories that have entered cars in the Munsey tour. Another departure from the old order of things is the changing of the cars from classes to divisions, ranging from division 1, for cars costing $850 and under, to division 6, for cars listing at $4,001 and over. Division 1 cars will be started first, followed in rotation by the other divisions. Cars in divisions 4, 5, and 6 will average 20 miles an hour; those in divisions 2 and 3, 18 miles, and those in division 1, 16 miles. The new rules are very comprehensive and embrace 162 different paragraphs.

Handsome trophies will be awarded the winning car in each division, in addition to which there will be a grand sweepstakes prize to be awarded the car making the best mechanical and road score. In addition to these awards, the entrance money will be divided among the drivers of the winning cars in each division. Thirty-one cars, embracing 26 different makes, have been entered to date. The latest entries include a Renault, entered by L. H. Shaab, Baltimore representative of Renault Freres, and a Hupmobile, entered by the Hupp Motor Car Company, of Detroit.

MILWAUKEE PREPARES FOR ITS "24"

MILWAUKEE, WIS., Sept. 6—Under the auspices of the Milwaukee Automobile Club the third annual 24-hour race will be held this year on September 24 and 25, on the State fair grounds track. As usual it will be the leading event of a two-days' speed carnival, and the shorter contests will range from the one mile to that of 100. The programme is still being made up. The entire meet will be conducted with an A. A. A. sanction.

Extraordinary preparations are being made for the races, especially for the round-the-clock grind, and from September 23 to 26 the fair grounds will be under martial law, with the State troops in full charge. The mile course is one of the best in the West, and it will be made still better in the coming weeks, for immediately after the 1909 fair, lasting until September 17, the club will have men upon it to put it in splendid shape. The turns will be reconstructed, oiled, and rolled to a stone-like surface. An original unit lighting system will be installed, consisting of 200 lights of 300 candlepower each, 20 feet apart. Lee A. Dearholt is chairman of the club's racing board and will again have charge of the events. President Clarke S. Drake will again be the referee.

An innovation in track racing will be seen in the arrangement of the repair pits directly before the grand stand, as in road contests. The enclosure of former years will be used as a parking space, and other quarters will be given in which the reserve crews may rest and have their meals.

TWO ENDURANCE RUNS IN NORTHWEST

Minneapolis, Minn., Sept. 4—This city has been the center of two endurance contests within a few days, the first being that under the auspices of the Minneapolis Tribune, to Duluth and return, and the second being the "Little Glidden Tour" of the Minnesota State Automobile Association. The former was held on Tuesday and Wednesday of last week, and the latter between Friday of last week and Tuesday evening.

Jean Bemb, in the Chalmers-Detroit, with which he won the Detroit trophy in the Glidden tour, was the victor in the Tribune run to Duluth and return, with the Franklin, driven by Carris, second; another Chalmers-Detroit, third; Walter C. Winchester, in his Pierce-Arrow Glidden winner, fourth; and a Ford was fifth. The run was a combination of the regular endurance contest with note taken of gasoline and oil consumption, and technical examinations. The big Pierce had the best record in the gasoline efficiency contest, showing 26.43 ton-miles to the gallon, while its nearest competitor had a mark of 20.73 ton-miles. The scores at the finish were: Chalmers-Detroit, 957; Franklin, 936; Chalmers-Detroit, 932; Pierce-Arrow, 926; Ford, 839; Pullman, 816; Gaeth, 813; Ford, 760; Lozier, 641. The Franklin had the only perfect road score.

The annual tour of the association started with 16 cars in line. The first day was a run to Alexandria, the second to Fargo, N. D., where Sunday was spent, and the stop on Monday night was at Benson, reaching this city on Tuesday evening. At the finish there were but seven cars with perfect road scores, and two of these were penalized in the technical examination. The five perfects were: Packard, driven by H. J. Clark; Pierce-Arrow, Reuben Warner, president of the St. Paul Automobile Club; Chalmers-Detroit, Barclay Automobile Company; Chalmers-Detroit, H. S. Johnson; and Brush runabout, Will Kemp. The two others with clean road slates were: Apperson, Basselle Automobile Company, and Ford, George Doerr. The performance of the little Brush was considered phenomenal. The penalties inflicted were as follows: Lexington, Haynes Automobile Company, 6.3; Oldsmobile, H. S. Johnson, 6.5; Cadillac, R. Stanvard, 7; Ford, A. Hanson, 10; Franklin, Theodore Wetmore, 10; Hupmobile, 40; Apperson, Ford; Haynes, Burney Bird, withdrawn, 1,000; Glide, Col. F. M. Joyce, withdrawn, 1,000; Glide, F. E. Murphy, not reported.

FIVE-DAY TOUR FOR HOUSTON AUTOISTS

Houston, Tex., Sept. 4—In the interests of the automobile dealers and owners in this city, the Houston Post is preparing a five-day endurance contest. The trade has liberally supported it and from present indications the event will have at least 30 entries, many of which will be the 1910 models. The start has been scheduled for September 24 and advices from along the route promise a hearty reception everywhere. As laid out now, the following is the itinerary: Houston to Victoria, 125 miles; Victoria to San Antonio, 130 miles; San Antonio to Austin, 80 miles; Austin to Brenham, 80 miles; Brenham to Houston, 86 miles; total 501 miles. The contest will be held under the rules and sanction of the A. A. A., such as those used in the last and most interesting Glidden Tour.

The Post has offered the main trophy, and it is likely that others will also be added by other parties, in order to make the affair more interesting. It is felt here that while the daily runs are not long, and the roads are generally fair and good, there will be plenty of ways in which the contesting machines will be well tried. The event is in the hands of a committee of which O. J. Lorehn is chairman.

COLUMBUS, O., PLANS 24-HOUR RACE

Columbus, O., Sept. 6—It is probable that a 24-hour race will be the feature of the October meet under the auspices of the Columbus Automobile Club. The event will be held upon the local one-mile track, and the details are now being arranged.

DENVER OUTLINES WORK FOR 1910

Denver, Col., Sept. 4—That the activities of the Denver Motor Club for the coming year may be well known before time, and to avoid conflicts, the officials of the club have announced the following contests: Two road races, one on Decoration day and the other on Labor day; reliability contest in June; gasoline economy contest in October; hill climb in November. This list is as comprehensive as possible, including all the important forms of automobile trials, and should give to the people of this section a well-defined knowledge of the cars being sold here. In addition to the above competitions, there will be considerable interest in the annual automobile show, which will be held in January or February. The preparations for these various events are under way, and some have been led to advanced stages. The show has been arranged to take place at a time when it will be possible to secure some of the exhibits from the New York exhibitions.

In the meantime, however, the club members are very busy with road and sign work, and the development of the club as a power in the State. An information bureau has been established so that local or visiting autoists may obtain correct data regarding the routes to all parts of the State. Guide books giving the directions, the distances, grades, road conditions, and legal ordinances have been prepared, and are given upon request. The membership of the organization has now passed the 550 mark.

Special interest attaches to the work for improved roads, for the Legislature has begun to realize the necessity for better highways, or rather for highways themselves. Extensive campaigns have been outlined for the building of bridges where at present none exist, and for constructing roads in several directions. The experience of the Glidden tour and the immense amount of publicity given to the fact that in some places, Colorado roads are such only on maps, has influenced many of the legislators. The Motor Club has invited the Rocky Mountain Highway Association to join hands with it in the crusade. The former is engaged at present in erecting sign boards on through routes and by the first of the year this will have been completed. The nuisance of overflowing irrigation ditches has attracted attention, and the members of the club are supplied with postal cards on which to send notice of such trouble to the club headquarters. There is a law against allowing the water to flow over the banks when such injures the public highways, and the officials in many places have been lax about preventing recurrences.

NEW AUSTIN CLUB DESIRES SANER LAW

Austin, Tex., Sept. 4—With a primary object of securing more reasonable and liberal city speed ordinances, the Austin Automobile Club has been formed in this city, with about 50 charter members. A temporary organization was effected with A. C. Goeth as temporary chairman, and O. E. Millican as temporary secretary. The meeting was held in the council chamber at the City Hall, and immediately after forming, the autoists were invited to confer with Mayor Wooldridge and the City Commissioners in regard to the speed regulations.

A committee to draft a constitution and by-laws is composed of Dr. T. J. Bennett, Pierre Bremond, and H. A. Wroe. The committee which will have charge of the interests of the club along the speed legislation lines includes Frank M. Covert, E. B. Robinson, and R. M. Thompson.

CLUB FORMED IN HEREFORD, TEX.

Hereford, Tex., Sept. 3—The Hereford Automobile Association has been organized recently in this place with the following officers: President, W. H. Ray; vice-president, Dow Mercer; secretary, R. F. Rogers; treasurer, W. O'Brien. The purposes are declared to be to secure improved roads and sports. Efforts are being made to arrange for a fine track where automobile races might be held.

DETROIT MAKES GOOD ON 50,000 PRODUCTION FOR 1909

By LEN G. SHAW

DETROIT, MICH., Sept. 5—Nine months ago—to be exact, December 17 last—THE AUTOMOBILE published a comprehensive review of the local situation, based on a most thorough investigation, showing how Detroit, as the hub of the automobile industry, would produce 50,000 cars in 1909.

How well that prediction was fulfilled furnishes interesting reading at this time, when several of the local factories are practically cleaned up on their 1909 output, and in at least one instance, 1910 models have been on the market for two months, or, strictly speaking, have been delivered to customers for that length of time.

The statement that Detroit would produce 50,000 cars was greeted by many with derision; and not without a show of reason from their point of view. It was argued that such a feat would be a mechanical impossibility. Time was when it would, but that day is past, never to return. Many, who had been content to regard with wonderment an annual output of from 500 to 1,000 cars per factory, insisted that such increases as talked of came only with an aggravated attack of automobilis, or was the emanation of a publicity man's fancy run wild. Others, some of them experienced men, looked askance at such figures, and said that if factory managers lived up to predictions, storage space would be in great demand, with a sufficient number of cars left on hand to meet all requirements for years to come.

They were wrong. Detroit not only fulfilled the predictions made by THE AUTOMOBILE but will exceed the aggregate given by a considerable amount, and local manufacturers are preparing to perform even greater wonders next season. Furthermore, the entire output is disposed of, and in a majority of cases every energy has been directed toward keeping up with a demand that taxed every facility to the utmost.

In reviewing the situation and showing what has been accomplished, it is well to take the figures appearing in THE AUTOMOBILE last December and supplement them with the actual output.

Taking the factories in the order enumerated, the first column of figures showing the makers' plans, the second the estimated production by THE AUTOMOBILE, and the third what has actually been accomplished, or will be by January 1, gives these results:

	Makers' Plans	Estimated Production	Actual Production
Ford	25,000	20,000	20,000
E.-M.-F.	12,000	8,000	10,000
Cadillac	10,000	9,000	9,000
*Blomstrom (Gyroscope)	5,000	2,500	500
Chalmers-Detroit	3,000	3,050	3,100
Brush	3,000	3,750	3,000
Packard	1,500	2,000	2,303
Regal	2,000	1,000	1,500
Herreshoff	500	350	500
-Hudson			
-Hupmobile			

*Estimated.
-Not in existence when December computation was made.

In the foregoing table it will be seen that there are several variations alike from the manufacturers' plans and the estimated production, although in the aggregate the latter is remarkably accurate. It will also be observed that, with two exceptions, the actual production is equal to or in excess of the estimate.

The Blomstrom Gyroscope, a new proposition, was handicapped in several ways. Just how many machines will be produced during 1910 cannot be determined at this time, owing to impending changes in management and the probable removal of the business to another city.

The other concern which fell below the estimate made by THE AUTOMOBILE was the Brush Runabout Company. That was due to the liberality of the investigator, who added 750 cars, rather than to any failure of President Frank Briscoe's plans or lack of popularity on the part of the car.

"We planned to produce 3,000 runabouts, and that is the number we will actually turn out," said Mr. Briscoe. "We couldn't have made any more, no matter how urgent the demand. We have worked to the limit of our present capacity. Next year we will more than double this ouput. We are contracting for materials for 6,000 runabouts, hope to make 10,000, and will probably turn out at least 8,000. Our 1909 business is practically all cleaned up, and the 1910 models, involving no marked changes, will be coming through early in November."

In support of Mr. Briscoe's statement regarding next year's output is the fact that work has been begun on a new plant that will when completed treble the present facilities.

The Ford plant at the end of 1909 will have turned out 20,000 of the popular-priced cars, a record that will probably stand for some time as remarkable in automobile production. The factory that was supposed would be ready for occupancy February 1 is not yet fully in commission. An addition is being erected, and other buildings are under consideration. The new factory will be in commission late this fall.

At the present factory 450 cars are coming through each week. This is an average of seventy-five a day, all the plant can handle. Out at the new factory it is claimed that it will be possible to put 1,350 cars through in a week if desired. These are astounding figures. Two hundred and twenty-five cars in a working day of ten hours means that a completed automobile will be turned out every two and one-half minutes.

Next door to the Ford factory, the E. M. F. Company, in point of age still in its swaddling clothes, but in reality the liveliest infant of them all, is doing things that have caused the trade at large to sit up and take notice. General Manager Walter E. Flanders denies any knowledge of the existence of a dull season in the automobile business.

"There will always be an abnormal demand for cars in the spring," said Mr. Flanders, 'but to the live manufacturer the rest of the year is going to be good. The trouble with some concerns in the past was that as soon as the weather began to warm up, the sales department got lazy and decided to suspend operations for the rest of the summer. The manufacturer was to blame, too, for just about the time the factory should have been straining every energy to keep up with the demand he began shouting so loud about 'next year's model' that prospective purchasers decided they would wait and see what the new wonder was like, instead of investing in a car that, according to the manufacturer's own admission, would be a back number the following season. Now they're bringing out a good model and sticking to it. What's the result? Last month we shipped 1,100 cars, and we're going to keep right on doing the same thing month after month, except that next year—not next season, mind you, for it's an all-the-year-'round season with us—we will be making more cars than ever before."

By the end of the present year 10,000 E. M. F. "Thirties" will have been turned out and disposed of. Next year, according to Mr. Flanders, 30,000 to 32,000 cars will be turned out. Of this number 15,000 will be "Thirties." The rest, somewhere between 15,000 and 20,000, will be the Studebaker-Flanders "Twenty," a new Flanders creation, a four-cylinder car selling at $750, that will make its appearance the latter part of the present year. In anticipation of increasing demands, the E. M. F. plant is being increased in size nearly one-half. The new car will be made in a separate plant, located in another part of the city, where the present equipment is being increased to a point that will render possible the production of the estimated number of cars.

The Cadillac "Thirty," picked as one of the year's winners, more than fulfilled expectations. By the end of 1909 fully 9,000 of these cars will have been placed on the market, representing all that could be done and Cadillac quality be maintained. Henry M. Leland, who is in direct charge of the mechanical department, receiving his schooling in the old days when the apprentice, who finally became a journeyman, knew his trade from beginning to end and backward. It is not enough to be up with the times. Mr. Leland and his associates believe in keeping a little ahead, and as a result every device that counts for accuracy or a saving of time without impairing results is to be found here. Since last fall the Cadillac has been running a night shift, and the plant's capacity in the matter of output has just about been reached. While not caring to venture a prediction as to next year, the Cadillac people are planning to duplicate this year's performance, and a little more, if possible.

If the Packard people have any weakness, it is a leaning toward conservatism in the matter of predictions. A year ago in answer to an inquiry the anouncement was made that in the neighborhood of 1,500 cars would be produced for 1909. As a matter of fact, that figure was exceeded by exactly 803, the last of the 1909 Packards to leave the factory being 2,303. There was just one reason that could be assigned for this increase—the ability of the factory to turn out that number and maintain the Packard standard. The thorough-going methods that have made the Packard famous wherever automobiles are known have a tendency to limit production. This is not without its advantaages, for with a car of such recognized excellence and a limited production, it follows that the person desirous of securing one places his order in good season. However, General Manager Waldon would in any event have no difficulty in disposing of the entire output, and it is a knowledge of this fact, together with a desire to meet the constantly increasing demands without sacrificing a single iota in quality, that is causing the company to prosecute building operations on a hitherto unheard-of scale. This increase in facilities played an important part in enabling the Packard company to turn out 1,502 "Thirties" and 801 "Eighteens" during the year. Further additions now under way or contemplated will make it possible to produce approximately 3,000 machines during 1910. As a matter of fact, deliveries on next year's cars began early in July, and between 700 and 800 have already been sent out.

The Chalmers-Detroit is another concern that more than lived up to expectations, exceeding the mark set a year ago by 100 cars. It took that many more "Forties" than originally planned to meet the most pressing demands, bringing the year's total up to 3,100. Of this number 2,500 were "Thirties" and 600 "Forties." The original building of the present plant contained some 72,000 square feet of floor space. Machinery is just being installed in a new four-story building having 96,000 feet of floor space, and work is in progress on a third of like size that will be ready for occupancy by winter—November 15, the contractors say. This will give the Chalmers-Detroit company the room it has long needed, and accordingly 5,250 cars have been contracted for for 1910.

The Regal split the difference between the makers' plans and estimated production, the fifteen hundredth car winding up the season, being shipped September 1. This is a highly creditable showing when the handicap in the way of factory room under which the Regal people labored is taken into consideration, and the popularity of the car is demonstrated by the early cleanup. For 1910 the company plans to build 5,000 cars. There is no apparent reason why it should not succeed. Three times the present floor space will be available because of new buildings that are going up, and at all events this year's output will be greatly increased.

By the end of January, which closes the factory year at that plant, 500 of the Herreshoff cars will have been placed on the market, according to Charles F. Herreshoff, president of the company, and who is in direct charge of affairs. For a time considerable delay was experienced in getting motors, of Mr. Herreshoff's own design, but that difficulty has been obviated and everything is running smoothly. For 1910 a like number of cars will be produced, according to present plans. In this connection comes the interesting announcement by President Herreshoff that next year's sales will be handled direct from the factory, instead of through a middleman, as was the case this season. Harry Houpt, who controlled the entire output this year, may continue to handle the car in New York, but the rest of the country will be cared for by the company direct.

Two concerns that did not figure in last December's computation, not being in existence at that time, are looming strong above the horizon, and have already succeeded in materially swelling the total output of Detroit's factories. These are the Hudson Motor Car Company and the Hupp Motor Car Company. The former is located in the old Northern plant, which is well adapted to its purposes, and where cars are being turned out at a lively rate. The fact that operations were begun only a few months ago means little in this case, as with such experienced men as Hugh Chalmers, R. B. Jackson, F. O. Bezner, Howard E. Coffin and others identified with it, the company is in reality as well off as the average veteran. The advent of the Hudson "Twenty," which is listed at $900, was the signal for a rush on the part of dealers, and it is asserted that the entire year's output was contracted for three weeks after the first announcement. By January 1 next, according to present calculations, 2,500 "Twenties" will have been turned out. What next year may bring forth is not disclosed, those in charge preferring to await developments. However, in anticipation of an increased demand plans have been made for enlarging the factory's capacity.

Although the Hupp Motor Car Company did not get under way until last March, the end of 1909 will, according to Vice-President R. C. Hupp, find 2,500 of the little cars on the market. The chief difficulty experienced by the company has been in filling orders. Trouble from this source will from now on be eliminated, the concern having just moved into a new factory on Jefferson avenue that will prove adequate for a long time.

"We will build 5,000 cars next year," is the prediction of Vice-President Hupp. "In general lines the 1910 model will differ little from our this year's car. It will contain numerous refinements, however, and be even better than the original model."

Taking the foregoing figures, and in each instance applying the minimum selling price, it will be found that Detroit's contribution in the way of automobiles for 1909 possesses an aggregate sale price well in excess of $52,000,000. When it is further stated that the coming year will probably see the addition of a half dozen large automobile plants, one begins to understand what the automobile industry means to Detroit, or what Detroit means to the automobile industry.

Some Recent Projected Factory Plans

Detroit, Sept. 5—Detailed plans for the immense plant of the Brush Runabout Company have just been completed. There will be four structures, including a two-story office building, 63 x 71 feet; an experimental building, 276 x 150 feet; finishing building, 208 x 150 feet, and a foundry 75 x 50 feet. The buildings will be of brick and steel, and will have all modern accessories of finish.

The Packard Motor Car Company has just let contracts for an additional office building, 508 x 60 feet, to be erected in connection with its plant at Grand boulevard and the Belt Line.

The Michigan Auto Parts Company will build a factory addition one story in height and 168 x 71 feet on the ground adjoining its present plant at Jefferson and Campbell avenues.

This showing for a single week, coupled with the fact that nearly every other automobile factory in the city is engaged in increasing its capacity, indicates that manufacturers are not only satisfied with present conditions but have confidence in the future.

Another Newcomer to Hail from Detroit

Detroit, Sept. 7—The Krit Motor Car Company is the latest addition to the local automobile colony, articles of incorporation having just been filed. The company is capitalized at $100,000, of which $50,000 is subscribed and $23,000 paid in in models, specifications, machinery and completed cars. A four-cylinder car designed by Kenneth Crittenden will be manufactured and marketed. It is announced that a factory capable of turning out 2,500 cars a year will be erected.

NOVEL DECORATIONS FOR PALACE SHOW

Something entirely new in decorative effect will be witnessed at the opening of the Tenth International Automobile Show in the Grand Central Palace, New York City, on New Year's Eve. A trellis garden scheme, with lattice work intertwined by myriads of electric lights and huge fire balls, landscape effects, pictorial scenes, and floral designs, will be included in the materials which will absolutely transform the big building. At the recent meeting of the show committee, of which R. E. Olds is chairman, representing the American Motor Car Manufacturers' Association, the Importers' Automobile Salon, and the Motor and Accessory Manufacturers, it was decided to award the contract to Unitt and Wickes, of New York. It was this firm which presented plans for the trellis garden.

From the front door to the rear will be in the hands of this firm of decorators, beginning with a handsome porte-cochere outside of the building, of a different design from the one used last year. At the back of the main hall will be erected gigantic French glass mirrors, in front of which will be an electric fountain, and between these two will be the bower. The garden influence will permeate everything, even to the furniture in the exhibition spaces. The concern which has this in charge is a leader in this kind of work in this country, its latest success being in the construction of the mammoth roof garden on the Hotel Astor. It promises that the plans and models, which indicate schemes entirely different for the Palace from anything before attempted in connection with automobile shows, will be definitely carried out. As formerly the active management of the show will be under the personal supervision of Alfred Reeves, the general manager of the association.

BRUSH SUCCESSFUL IN RURAL MAIL WORK

Ottawa, Kan., Sept. 4—With the growth of the rural mail service has come the usurpation of the horse delivery by that of the automobile. W. A. Johnson, of this place, recently purchased a Brush runabout with which to cover his 25-mile route. He has to make daily trips through the rough and hilly country west of here, and with his horse and carriage it was the work of an entire day, with 84 mail boxes to be visited. He has had the Brush some time now, and does the entire circuit in three hours with ease. The outlay for the Brush was $610, only a little more than was necessary for three horses and wagon, which was the equipment needed before. Mr. Johnson keeps a close account of his expenses, and finds that it is costing him at a rate of $61.80 a year for the maintenance of the car, and his entire repairs have amounted to less than $10, even when he was engaged in learning to operate it.

PACKARD CAPITAL NOW $10,000,000

Detroit, Sept. 7—The Packard Motor Car Company, organized eleven years ago under the laws of West Virginia, is now a Michigan corporation, articles of association having been filed at Lansing September 1. At the same time the capitalization was increased to $10,000,000, of which $5,000,000 is preferred and $5,000,000 common stock. Increasing business made it necessary to enlarge the capital stock. Extensive additions are being made to the plant to enable the company to avoid night work, it being the desire of President Henry B. Joy and his associates to make it a strictly daylight factory.

ELKHART CARRIAGE MAKERS ENTER TRADE

Elkhart, Ind., Sept. 6—The Elkhart Carriage & Harness Manufacturing Company has decided to enter the automobile field and has drawn up plans for its product. The car will have a motor of from 30 to 35-horsepower, with the engine, clutch, and transmission in a unit. The rear axle will be full floating, with the housing of pressed steel, the wheel base 117 inches, and the wheels 24 inches in diameter. Three styles of bodies will constitute the line, the standard five-passenger touring car, the baby tonneau, and the roadster. The first lot of machines will be ready for exhibition purposes during the early part of October.

SMITHS RETIRE FROM OLDS MOTOR WORKS

Detroit, Sept. 6—Bentley J. Mead, general sales manager of the General Motors Company, is the new secretary and general manager of the Olds Motor Works, Lansing. Frederick L. Smith, vice-president and general manager, and his brother, Angus, secretary-treasurer of the Olds company, have resigned, and the duties of secretary and general manager have been assumed by Mr. Mead, who is regarded as direct representative of the General Motors Company, which recently acquired the Olds plant.

Announcement of the change came as something of a surprise, but directors of the company decline to discuss the matter, while both the Smiths, who are well known in the automobile world, refrained from commenting on the situation further than to state they had other plans in view that would occupy their time fully.

It is understood that the Smiths are interested in the organization of a new automobile company, to be promoted by Ralph R. Owen, who has resigned as factory manager for the Olds company, although he will have no active part in the management. There is a strong likelihood, in case the deal goes through, that the plant will be located in Detroit.

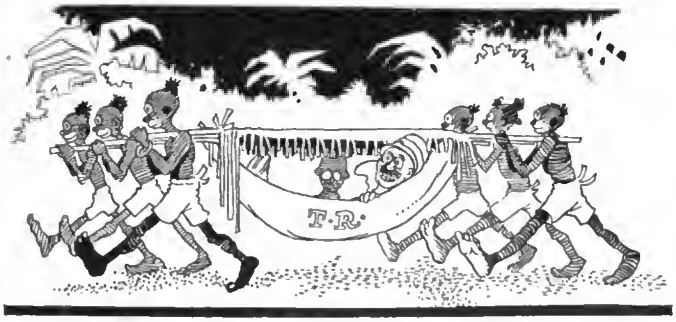
What Mr. Selby's Winton Found in Town of Casey, Ill.

Near Ellensburg, Wash., Roads at Least Had Foundation

Where the Roads in Town Were Somewhat Inferior to Traveling in the Open Country

Mr. and Mrs. W. G. Selby, of Marietta, Ohio, have arrived at Seattle in their Winton Six, having taken 29 days for their overland journey from Pittsburg to the exposition city. On the trip Mr. Selby states that he cleaned one spark plug; otherwise the motor never gave him a moment's thought. From Seattle, Mr. and Mrs. Selby will tour to Los Angeles and thence home via Salt Lake City

"T. R." UTILIZES AFRICAN "SIX"



From the "Auto Era," Published by Winton Motor Carriage Co.

NEW YORK Y. M. C. A. OPENS AERO SCHOOL

To meet the prospective demand for men trained in the various branches of aeronautics the New York West Side Y. M. C. A. is to conduct an evening course in that science, under the direction of Wilbur R. Kimball, of the Aeronautic Society. This school owes its existence to an experimental course of lectures given last winter by Cortlandt Bishop, Augustus Post, W. E. Scarritt, and others. The course will be principally devoted to aeroplanes, as these are believed to be susceptible of the most development in the future. Much of the equipment of the automobile school already conducted by this organization will be used in the new school. No actual practice in aviation is at present contemplated, but this feature may be added.

WARNER ORGANIZES NEW GEAR COMPANY

TOLEDO, O., Sept. 4—T. W. Warner, formerly of the Warner Gear Company, of Muncie, Ind., has organized the Warner Mfg. Co. in this city to make change-gears, differential and steering gears. At present the company is located in the old Pope-Toledo plant, in buildings rented from the Overland Automobile Company, which is one of its largest customers, and is employing 200 men. This arrangement is only temporary, however. Mr. Warner says that he will build a new plant either in Muncie, Ind., Toledo, or Detroit, to be finished within three months.

INSTRUCTING OWNERS IN CARE OF CARS

Admittedly the greatest obstacle to securing possibilities of efficiency and long life, which are latent in almost every automobile, is the indifference and neglect of the operator; and, further, that neglect has its most immediate and far-reaching influence when it affects the lubrication. Few drivers are so criminally careless as to forget to replenish the mechanical oiler and crankcase supply, and most of them refill the gear-box and the rear-axle casing occasionally; but the many small oil holes and grease cups, which of necessity must be scattered over the chassis, are too frequently neglected. As a reminder to owners and chauffeurs of their duty in this respect, the Stevens-Duryea Company has included in its instruction book a double-page plan view of the chassis, with all oil holes and grease cups indicated by arrows and reference numbers, and a table to correspond showing the intervals at which each should be given attention. The illustration is so clear that the veriest novice could not go wrong.

No.	Parts	Lubrication	Give Attention	Miles	No. of Places on Chassis
1	Front Hubs	Grease		1,000	2
2	Steering Knuckles	Grease		200	2
3	Springs	Oil	Every day	....	2
4	Carburetor Primer	Oil	Every day	....	1
5	Starting Handle	Oil	Every day	....	1
6	Steering Rod	Oil	Every day	....	2
7	Fan Support	Oil		300	1
8	Tie Rod	Grease		200	2
9	Fan Bearings	Grease	Every day	....	1
10	Springs	Oil	Every day	....	2
11	Springs	Oil	Every day	....	2
12	Valve Tappets	Oil	Every day	....	8
12A	Rocker Shaft	Oil		300	4
13	Magneto	Oil (light)		500	2
14	Magneto Connection	Oil	Every day	....	1
15	Magneto Bearings	Grease		200	1
16	Steering Post	Grease		750	1
17	Timer	Oil	Every day	....	1
18	Steering Post	Oil		200	1
19	Clutch Bearing and Brake Pedal	Oil		200	2

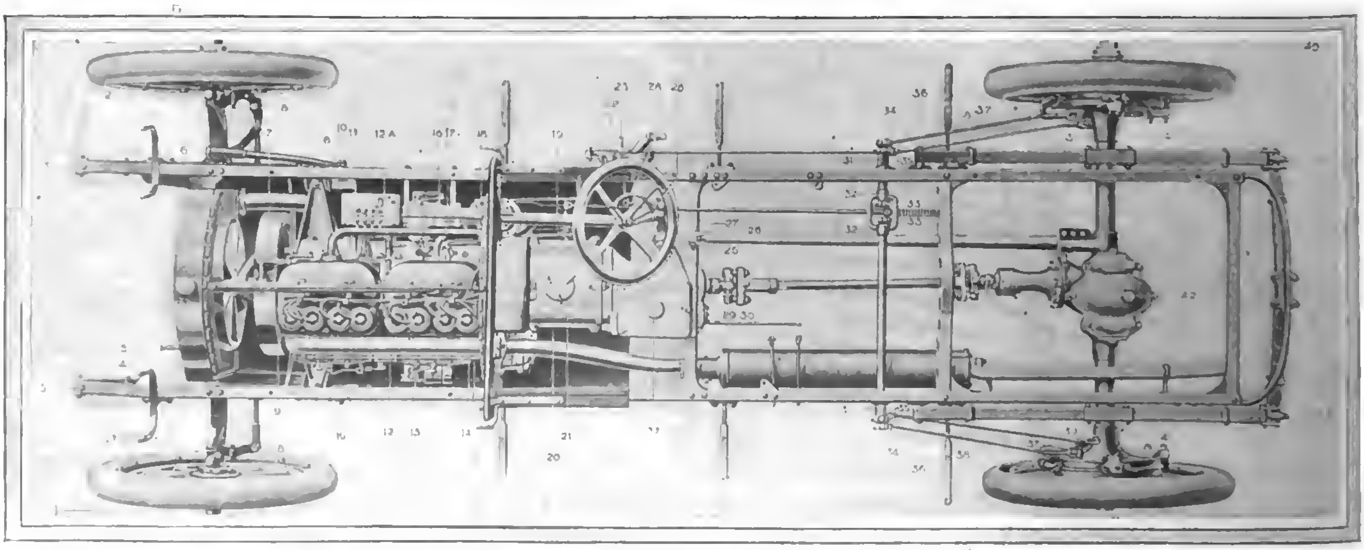
43	Springs	Oil	Every day	....	2



Chassis of Stevens-Duryea "Four" with Parts Numbered, to Be Used with Lubricating Table Printed Above

Told in the Progress of the Industry

Timken Company Host of Factory Organization—To show its appreciation of the manner in which its factory organization has responded during the formative period of the new plant, the Timken-Detroit Axle Company last Saturday acted as host. The factory employees were given a yachting party to Wolf's Point, Can., and a dinner there, after athletic sports. In the evening the commercial department and the heads of the several branches of the big industry were tendered a banquet at the Hotel Tuller. The celebration was over the remarkable showing that has been made by the officers and men of the concern in building up the present axle business since July 6. On that date the Timken Roller Bearing Company, of Canton, moved its axle plant to the City of the Straits, a new factory was started, an organization perfected, and deliveries made on contract time.

What it Costs to Guarantee Studebaker Cars—A question which has agitated the minds of many manufacturers of automobiles is that of the cost of guaranteeing the products. The standard warranty of both national organizations covers only 60 days, for defective workmanship or material. One of the concerns which has guaranteed its output for a year is the Studebaker Automobile Company, and a recent appraisal was made of the cost of this service. It has marketed 1571 Studebaker-Garford chasses, and the company has been extremely liberal in carrying out its promises. It came as a surprise, therefore, when it was learned that from March, 1905, to October, 1908, there had been expended a sum of $16,620.18 for the guarantee. This is an average of but $10.51 a car.

Fisk Tires Tested in Transcontinental—The worth of Fisk tires was recently shown in a double transcontinental tour, according to the information given by the Fisk factory. The tour was one made by Everitt Mead and A. Newton Mead, of Greenwich, Conn., in a Packard car, and 10,185 miles were covered. Leaving the East on May 19 they traveled overland with several makes of tires on the machine during the journey. At Los Angeles, they put a new Fisk on a rear wheel, and reached New York with the Pacific air still in it, not a puncture nor blowout having been experienced upon that wheel. The return trip included a long stretch of 1,600 miles to Seattle, over the Mount Shasta route, and the Siskiyou Mountains, before turning eastward over the Rockies and the great plains.

What Color for Municipal Automobiles?—This important question was a ponderous and facetious one in Boston recently, for an ordinance to prevent joy rides in the city's cars was passed. It required that the machines be painted a standard color, and that they bear the name of the city and the department on the side. The Mayor's cabinet first attempted to decide upon the color, but agreed to leave that matter to the art department. One man wanted Harvard crimson, another voted for pale lavender, another for crushed strawberry, and still another for lemon. The Mayor, however, decreed that the fire department might retain red on its autos, but suggested that the others be colored a standard black like his own.

Ajax Tires Score at Lowell—In the Merrimac Valley trophy contest of the light cars at Lowell, Mass., on Monday, the Ajax tires again made a splendid showing. They were used by the three Maxwell cars which finished second, third, and fifth, driven respectively by See, Costello, and Sickinger. These men drove the machines for 127 miles at high speed without a puncture and, according to the Ajax officials, were not handicapped with tire trouble of any sort. This showing is a repetition of the Ajax success at Savannah last year.

Will Exhibit Firestone Cars—The Columbus Buggy Co., of Columbus, O., is arranging to have large exhibits of its new gasoline cars at the approaching automobile shows. The firm is manufacturing the Firestone cars and the 1910 models are expected to be out in about 30 days. The machines at Atlanta will be in charge of L. E. Key. New York and Chicago are also on the list.

Another Carriage Maker in Line—The United States Carriage Co., of Columbus, O., has announced its intention of joining the manufacturers of automobiles and will have a four-cylinder gasoline car for sale next season. The line will consist of touring cars, runabouts, hearses, cabs and ambulances. It is expected that the first of the production will appear early in January.

Minneapolis Gets First Taxicabs—Minneapolis recently received its first taxicabs, and they are now upon the streets giving excellent service to a growing patronage. The McAllister & Newgord Co. introduced this method of transportation with 15 Fords, and it is understood that the Pence Automobile Co. will soon have 25 cars on the streets also. At present there is room for all comers.

Credit for Knox Photograph—The picture of the Knox car which won the 50-mile free-for-all on the Galveston Beach, as shown in last week's AUTOMOBILE, on page 413, should have been credited to C. C. Burns, who took it.

IN AND ABOUT THE AGENCIES

Pence Auto Company, Minneapolis, Minn.—One of the largest and handsomest buildings in this country devoted to the automobile trade has been opened by the Pence Auto Co. in Minneapolis. It is an eight-story structure of fireproof construction and with all the conveniences for garage, repair and selling work. The location at Hennepin and Eighth streets is almost in the center of the business section. The company was started in 1903 by H. E. Pence with a capital of $2,200, and its rapid rise can be imagined from the fact that the cars sold last year were valued at nearly $2,000,000. For the 1910 season, 3,750 machines have been ordered for the firm's territory, which includes this State, the Dakotas, and Montana.

Palmer & Singer, Philadelphia—The agency for the Palmer & Singer cars has been placed under the management of George P. Parker. Options have been secured on several Row locations and one will be selected shortly.

Morgan & Wright, Minneapolis, Minn.—The Minneapolis branch of Morgan & Wright, makers of the famous "Good Tires," was moved on September 1 to new and more commodious quarters at 911 First avenue, South.

RECENT BUSINESS CHANGES

Fort Worth Agencies Consolidate—Three automobile agencies in Fort Worth, Tex., were consolidated recently when W. J. Tackaberry and S. R. Wells, of the Runnells Automobile Company, sold their interests to E. P. Reynolds. The firm will hereafter be known as the Runnells & Reynolds Auto Company. E. F. Simmons is also connected with the concern, thereby bringing in the agency for the Stevens-Duryea. Five makes of cars will be handled, as follows: Chalmers-Detroit, Hudson, Stevens-Duryea, Ricketts Six and Regal. It is very probable that a couple of other lines will be added, in order to give a complete list of lines selling from $650 to $6,000.

Minneapolis Knox Agent Incorporates—The Mich Automobile Company, which has had the agency for the Knox cars in Minneapolis, has filed articles of incorporation, with a change of name. It will hereafter be known as the Mich-Stair Auto Company, with a capital stock of $50,000, W. A. Stair having joined as a partner. A new building will shortly be erected at First avenue and Eighth street, and other lines of cars added to the present one.

Morgan & Wright, Los Angeles, Cal.—The Los Angeles branch of Morgan & Wright, the manufacturers of M. & W. tires and rubber goods, was moved on September 1 from 118-122 East Tenth street to more commodious quarters at 1108 Main street. It now has greatly improved facilities for handling the trade, which is showing a healthy growth.

Tray Plate Battery Company Moves—The Tray Plate Battery Company, Binghamton, N. Y., has recently moved into its new large plant on Wall street. It is preparing for an increased campaign with the well-known "High Efficiency" non-sulphating batteries.

PERSONAL TRADE MENTION

E. LeRoy Pelletier has been appointed general advertising manager of the Studebaker Automobile Company and the Studebaker Bros. Manufacturing Company. He will have his headquarters at South Bend, Ind., instead of with the Studebaker E-M-F factory in Detroit. In his new capacity Mr. Pelletier will have full control of the advertising of the Studebaker horse-drawn vehicles as well as of the entire automobile business, which formerly was his special province.

S. W. Rushmore, of the Rushmore Dynamo Works, and Mrs. Rushmore, have recently sailed for Europe on the Mauretania. They will make a tour of six weeks' duration, during which time Mr. Rushmore will establish a branch in Berlin, where the Rushmore lights and generators have had a greatly increasing sale. The existing branches in London, Paris, and Milan will also be visited.

Len Zengle, the crack Chadwick driver who has been so successful recently in hill climbs and at Indianapolis, will shortly return to the Pennsylvania Motor Works factory at Bryn Mawr, Pa. He will, however, fill all of his driving engagements with the Chadwick Company until the close of the season.

Leon M. Bradley has been selected as manager of publicity for the Atlanta automobile show, which will be held in that city from November 6 to 13. Mr. Bradley retains his connection with the A. M. C. M. A. at the same time.

George S. Atwater, formerly with the Atwood Manufacturing Company, is now associated with the Tray Plate Battery Company, of Binghamton, N. Y. He will represent them in their sales department.

OBITUARY NOTICE

Edward M. Murphy, pioneer vehicle and automobile manufacturer, died suddenly of apoplexy at his home in Pontiac, Mich., on September 4. In 1887 Mr. Murphy settled in Pontiac, and the following year, with C. V. Taylor, organized the Pontiac Buggy Company. He was one of the organizers of the Oakland Motor Car Company and a stockholder in several other carriage and automobile concerns.

NEW AGENCIES ESTABLISHED

Marmon and Parry: Minneapolis, Minn.—Fawkes Auto Company, in addition to the American, Overland, Reo and Holsman.

Continental Tires: Milwaukee, Wis.—Welch Bros. Motor Car Company, Grand avenue and Seventh street. For eastern Wisconsin.

Haynes: Houston, Tex.—Mosehart & Keller Automobile Company, for Texas, Southern and Western Louisiana.

Velie and Hupmobile: Cincinnati—Evanston Automobile & Garage Company, 3705 Main avenue.

Stevens-Duryea: Pittsburgh—E. O. Vestal, The Rittenhouse, North Highland avenue.

Winton and Regal: San Antonio, Tex.—C. H. Dean, 234-238 South Flores street.

Haynes: Greenville, S. C.—B. W. Martin, for Greenville and adjoining counties.

Regal: Greenville, S. C.—W. H. Irvine, Jr., for Northwestern South Carolina.

Studebaker: Roanoke, Va.—Valley Motor Vehicle Company, Limited.

Detroit Electric: Minneapolis, Minn.—Hathaway-Stimson Company.

Stevens-Duryea: Minneapolis, Minn.—M. R. Waters & Sons.

White: Sioux City, Ia.—Bennett Auto Company.

Empire: Minneapolis, Minn.—Maxfield Auto Company.

Overland: Tampa, Fla.—Hobbs & Knight Company.

Croxton-Keeton: Pittsburgh—Fred W. Fischer.

Franklin: Baltimore—Mar-Del Mobile Company.

RECENT INCORPORATIONS

Harper Livery & Sale Company, Salisbury, N. C.—Capital $50,000. To operate livery and sale stable with privilege of operating automobile lines in the State. Officers: President, J. P. Harper; vice-president, J. D. Heilig; secretary and treasurer, M. J. Ragland.

E. R. Thomas Motor-Branch Company, Boston—Capital $100,000. To deal in automobiles. Officers: President, E. L. Thomas; secretary and treasurer, J. M. Edsall; manager, C. S. Henshaw. Temporary offices at 288 Columbus avenue, Boston.

Citizens' Automobile Company, Birmingham, Ala.—Capital $25,000. To manufacture, sell, and lease automobiles, taxicabs, and auto accessories. Incorporators: J. C. Turner, M. F. Hinckman, H. G. Robinson, G. W. Yancey.

Trackless Trolley Company of America, New York—Capital $150,000. To manufacture automobiles, motor vehicles, bicycles and other vehicles. Incorporators: C. E. Barrett, A. L. Newman, Sadie Wiener.

Victor Windshield Manufacturing Company, Chicago—Capital $2,500. To manufacture windshields and automobile accessories. Incorporators: J. McGaffey, A. L. Haake, S. S. Gorham.

Hazard Engineering Company, Gates, N. Y.—Capital $100,000. To manufacture automobile and marine gasoline engines. Incorporators: E. C. Hazard, G. E. Hazard, W. J. Robinson, J. Bennett.

Automobile Service Company, Camden, N. J.—Capital $50,000. To operate taxicabs and automobiles for public use. Incorporators. F. R. Hansell, W. F. Eidell, John A. MacPeak.

Rainier Motor Truck Company, New York—Capital $50,000. To manufacture motor trucks for freight only. Incorporators: P. N. Lineberger, G. C. Comstock, J. T. Rainier.

Fox-Stiefel Company, New York—Capital $130,000. To manufacture and deal in goods for automobilists. Incorporators: T. F. A. Gibney, H. A. Herold, Simon Wickes.

Kemezite Company of America, New York—Capital $10,000. To manufacture and sell kemezite. Incorporators: L. W. Lisberger, Joel Jacobs, Edward B. Levy.

American Automobile Company, St. Joseph, Mo.—Capital $25,000. To deal in automobiles. Incorporators: W. G. Campbell, John F. Garber, C. R. Vaughn.

Elizabeth Taxicab Company, Elizabeth, N. J.—Capital $100,000. To manufacture automobiles. Incorporators: F. N. Voorhees, W. H. Cole, F. V. Price, Jr.

Franklin Square Garage Company, Worcester, Mass.—Capital $35,000. To do a general automobile business. President and treasurer, A. R. Davis.

Ranger Automobile Company, Chicago—Capital $25,000. To manufacture automobiles. Incorporators: G. A. Schmitt, E. A. Sanders.

Ewing Automobile Company, Cleveland—Capital increased from $150,000 to $175,000.

RECENT PUBLICATIONS

Stewart & Clark Manufacturing Company—Stewart speedometers for 1910, with all the improvements considered in detail, and the entire construction of the instruments explained, are well taken up in the new catalogue, just issued. This book of imposing size, beautifully printed, with exceptionally clear photographs, is the foreword of the Chicago concern, and the news it contains is of special interest to owners and dealers alike. In regular order the type of instrument is explained, and the principles of the operation of the multipolar action shown, as compared with other types, before introducing the new models themselves. Twenty-one different styles of speed recording instruments will be manufactured, and the new factory has a capacity which would supply a speedometer for every automobile built within the next 365 days. The long list includes those for automobiles, motorcycles, and motorboat engines. Of course, the majority are for the autos and are constructed to read mileages from zero to 90, with some stopping at intermediate points, such as 50, 60, and 75. A great deal of attention has been given during the preparation of the 1910 product to the fittings which go with them, such as dash brackets, electric lights, swivel joints, and wheel clamps, and improvements made in them all. The book is printed in two colors, orange and black, so that the subjects being discussed are well set out. It is bound in heavy stock.

Winton Motor Carriage Company, Cleveland—The Winton Six Upkeep Book, the second annual edition, has been issued to show the records of the Winton cars winning prizes for low cost of maintenance. The booklet is very artistically compiled, and the statements of the judges and of those who won are very interesting. That a car can be driven for 17,003 miles without a cent being paid for repairs is wonderful. Other sets of figures are of equal importance. In each case of the ten, the details of the records kept for eight months are given, sworn to by both the chauffeurs and owners. It is especially noteworthy that the first three prize winners this year were not new machines, and these facts are well brought out in the edition. Announcement is also made in it of a continuance of this novel competition.

The Autolight & Motor Supply Company, Philadelphia—This large, thick catalog will be a delight to every automobilist, as it is one of that welcome sort that is practically an encyclopedia of every accessory pertaining to the sport. The 155 pages contain descriptions and price-lists of everything from a spark-coil primary binding post washer at five cents to a 42x5 1-2 inch tire.

How an Automobile Truck Is Utilized to Transport the Ever Popular Moving-Picture Show

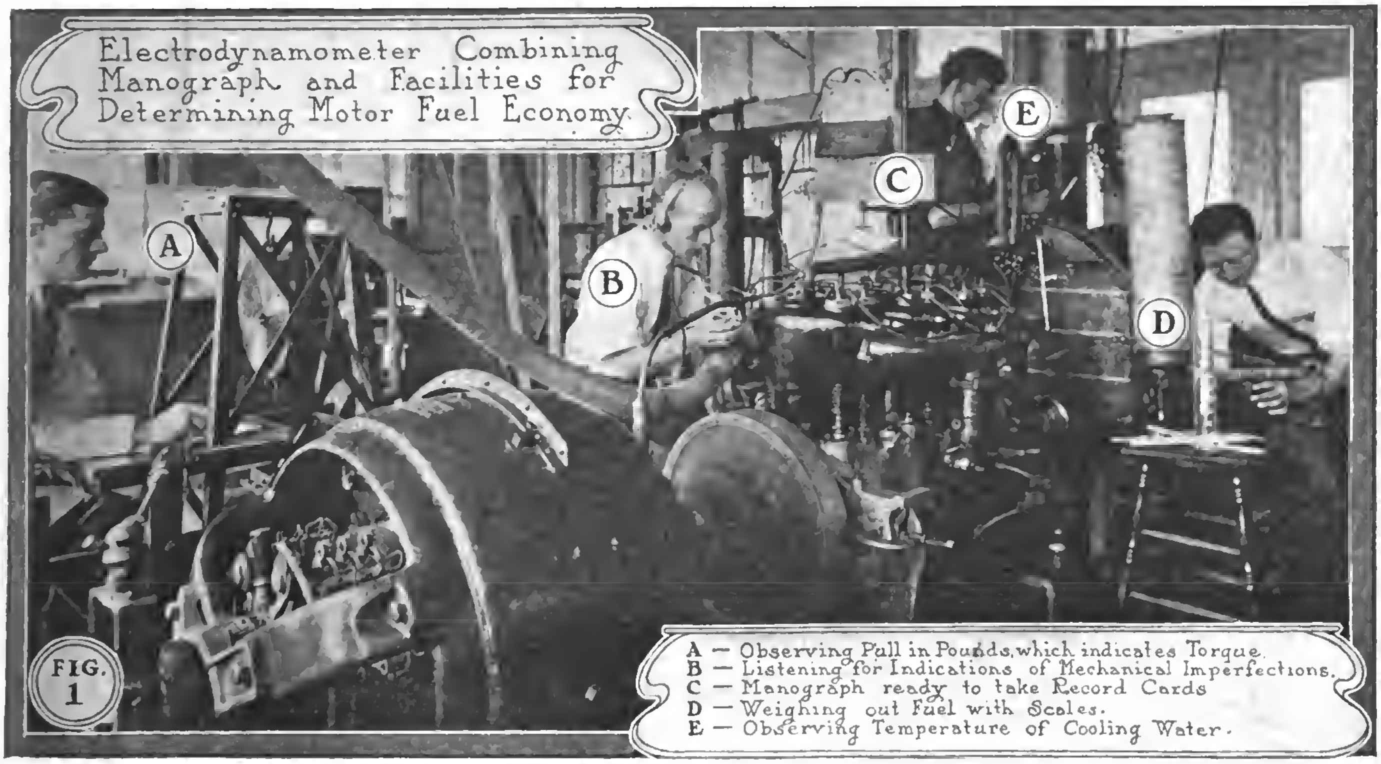
The truck, manufactured by John H. Blacker & Co., of Chillicothe, O., was fitted up by Albert Taylor, of Mt. Sterling, O., to carry his moving-picture show. The dynamo which furnishes the light and power for the show is driven from the flywheel of the motor. The car itself carries the tent, seats, and all other paraphernalia. After the show is over, Mr. Taylor gives his customers a ride in the sight-seeing car, which is also shown in the picture.

Vol. XXI NEW YORK—THURSDAY, SEPTEMBER 16, 1909—CHICAGO No. 12

THE AUTOMOBILE

LABORATORY IN AUTOMOBILE MAKING

By Thomas J. Fay



BUFFALO, Sept. 13—In the making of the automobile of to-day the laboratory supplies definite methods and eliminates chances inseparable from unfit elements and other equally wasteful channels. What was once done in the making of automobiles is no longer possible or advisable. In the first cars, considerable guesswork as to material and its enduring qualities caused breakages and discouragements, both to the man who made and the man who bought.

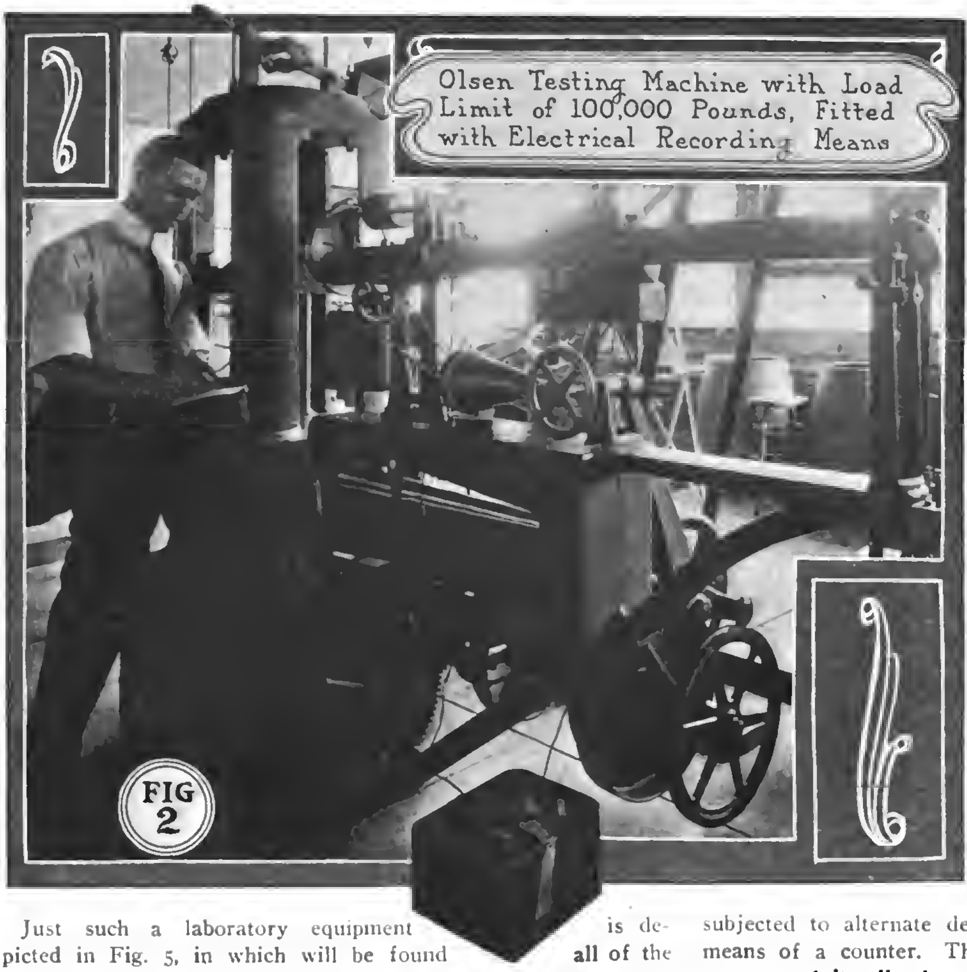
To learn that the 1910 cars have a laboratory foundation, it is only necessary to go into the establishment of a representative maker and study the up-to-date methods now employed. One there learns of laboriously-obtained engineering records calling for definite investigation of the qualities embodied before they are included in the final work of construction.

Nothing can be left to chance, no vendor's word can be safely taken for the quality of the material, and a corps of competent engineers must wait upon the men who do the work.

There is a widespread impression that the several makers of quality cars depend, for engineering information, upon one common laboratory, and that some one man is responsible for the qualities of the several grades of materials used in many makes of cars. This view of the situation merely indicates a vast lack of knowledge of the facts. Moreover, a moment's reflection is but enough to lead to the conclusion that the task is beyond a centralized laboratory, and to realize results as they must obtain in the cars about to be placed before discriminating buyers it is necessary for every big concern to have skilled men ready for instant action.

There are a vast number of reasons why each shop should have its own facilities, and the only way this phase of automobile building can be adequately explained is to investigate the situation in sufficient detail to bring out the points to be made.

Some of the Requirements in a Laboratory—The materials should be purchased on a basis of chemical composition—if they are to be heat treated, at any rate—for the reason that, in the absence of knowledge of composition, the heat-treating process will be attended with dangers, and, as is recognized, normal steel is better than heat-treated product if there is any question as to the composition. Heat treatment is necessary if the parts are to be up to the highest attainable standard. The first requirement in a laboratory is a suitable chemical equipment, by means of which every "heat" of steel or other metal, when it arrives, may be sampled at random, and the chemical composition ascertained.



Olsen Testing Machine with Load Limit of 100,000 Pounds, Fitted with Electrical Recording Means

FIG 2

Just such a laboratory equipment is depicted in Fig. 5, in which will be found all of the equipment necessary for determining alloy contents, carbon, silicon, sulphur, phosphorus, manganese, copper, arsenic, etc. In addition to these determinations, which must be made quickly, the chemist is engaged in the investigation of new products, and in trying schemes of heat treatment to bring out the qualities of the steel.

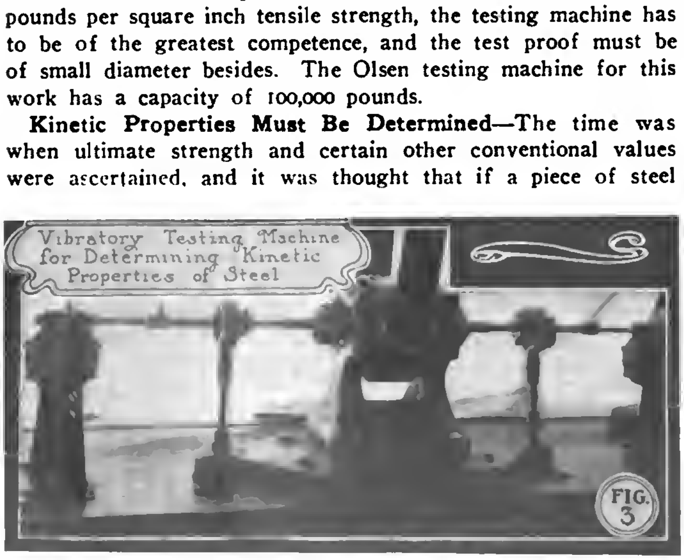
The chemist could not know, with any degree of certainty, whether or not a new mode of heat treatment would show positive advantages over a method in vogue were he not in touch with a physical laboratory in which to make and ascertain physical tests. Fig. 2 shows an Olsen testing machine used to determine the physical properties of materials, as ultimate strength, elastic limit, elongation between given limits, and reduction of area at the point of fracture. In these days, when steel for automobile parts frequently measures above 150,000 pounds per square inch tensile strength, the testing machine has to be of the greatest competence, and the test proof must be of small diameter besides. The Olsen testing machine for this work has a capacity of 100,000 pounds.

Kinetic Properties Must Be Determined—The time was when ultimate strength and certain other conventional values were ascertained, and it was thought that if a piece of steel were possessed of high attending elastic limit, elongation, and a good extension, that it would be suitable for any purpose. When automobiles came into vogue and the nature of the work was found to be of a character requiring more than static ability, kinetic life of steel was investigated at great length, and, among other facilities, the vibratory testing machine was devised. Fig. 3 shows just such a machine, built by the E. R. Thomas Motor Company for the purpose of testing all steel used, and it was naturally found that physical properties, even though they were very good, afford no guarantee of long life. After going into this phase of the material question at great length the Thomas company was enabled to eliminate all mysterious failures and reduce the factor of safety to definite values.

This testing machine rotates at a very high speed, and the materials to be tested are prepared, and, when adjusted into place in the machine, rotate under stress. The amount of stress is varied by altering the load, which is applied by means of weights, and the method of testing is such that the material may be stressed to any proportion of its elastic limit and subjected to alternate deflections, which are kept track of by means of a counter. The machine is very simple, free from errors, and it tells the vibratory value of the steel relative to a standard or in the abstract. The higher the stress in the steel undergoing test, the quicker it will fail, and the limits seem to stand between 400,000 and 1,600,000 vibrations when the steel is stressed to 65 per cent. of its elastic limit. Certainly, this is information well worth having, when account is taken of the performance of crankshafts, for illustration, in which it is impossible to assume with accuracy that a deflection is avoidable.

Bearings Demand Special Testing Equipment—When account is taken of the severe service rendered by bearings in automobiles, particularly since they are not always free from foreign substances, it is no wonder that the mind runs to ball and roller bearings, and if they are to be faithful to their work, some discrimination must be used besides relying upon catalogued information, which, in itself, may be quite accurate, but it may not properly apply. In every special case, in order to be sure of the results, it is necessary to test the ball bearings and find out if they will stand the class of service demanded of them. Fig. 4 is of a special ball-bearing testing machine built at the plant of the Thomas company to enable its engineers to cope properly with this problem, and with this machine the largest ball bearing used in any Thomas car may be tested under normal load to the end of its natural life; or it may be tested to destruction under predetermined conditions. Any type of bearing may be tested in this machine, and the loading, as well as the number of revolutions, may all be noted, either from time to time or at the end of the run.

Selections of Material for the Work—Different makers do not of necessity follow along the same lines, but there are certain market considerations which will be common to all, and in the selection of material, these influences must be taken into account. It is the function of the laboratory to tabulate the conditions, fix upon physical properties desired in view of chemical contents, and to so limit the specifications that the purchasing department will be able to procure what is wanted.



Vibratory Testing Machine for Determining Kinetic Properties of Steel

FIG. 3

promptly, and at a price consistent with the aims. In the Thomas plant the chemist has prepared specifications for the guidance of the several departments as follows:

PHYSICAL PROPERTIES OF STEELS

STEEL (Annealed State)	Elastic Limit	Ultimate Strength	Elongation	Reduction Area
N S No. 1	60,000	80,000 90,000	30%	65%
C S " 2	27,000	50,000	25%	60%
C S " 3	33,000	60,000 66,000	23%	50%
1550° F—Quenched in oil and drawn at 600°.				
N S No. 1	135,000	200,000	15%	50%
1500° F—Quenched in brine.				
N S No. 1	170,000 180,000	230,000 240,000	11-12%	40–45%
1450° F—Quenched in oil or water.				
C S No. 2	27,000 32,000	65,000	15%	40%
C S " 3	33,000 37,000	72,000	12%	35%

Note.—For shear or torsion use values 20% less than above; for compression use values given.

STANDARD HEAT TREATMENT

This is used by them for crank shafts, connecting rods and all nickel steel that is to be machined before use. After forging—anneal at 1450° F., cool in air, heat to 1500° F. and plunge in oil, draw at lowest point at which they will machine 950° F—1050°.

Gear Treatment—For parts where it is necessary to increase strength without increasing size, the following treatment can be used for 3½% nickel steel; it is, however, rather expensive.

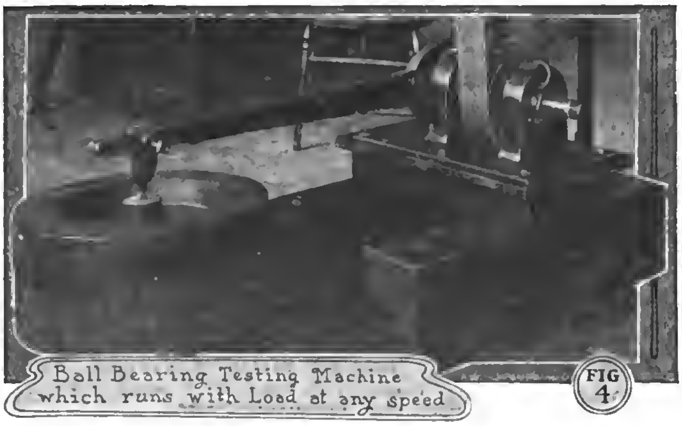
Pack harden at 1650° F., until carbon has penetrated a trifle over 1-64". Cool in pot until cold, reheat to 1500° F. very slowly. Plunge in Ca C/2 or Na Cl solution, 17° B., at 125° F. Reheat rapidly with very hot fire to lowest point at which steel will be hardened, which is 1325—1350° F.

In pack hardening use 40% new and 60% old bone. Bring up to heat for three hours and soak for three hours. As a rule the interior temperature of pots is about 50% below that of furnace even after prolonged soaking. It is a good idea to add charred scrap leather to bone bin from time to time. Take scrap leather and char in furnace.

Carbon penetrates 3½% nickel steel about 1-64" in two hours.

HEAT TREATMENT NOTES

T- 1 Transmission gears.
T- 2 Parts to be glass hard and no great strain.
T- 3 Bevel drive gears and pinions. Differential pinions.
T- 4 Small thin parts that are to be case-hardened.
T- 5 Any large work or local hardening.
T- 6 Propeller shafts and semi-floating type axle drive shaft or when bending and torsion is to be resisted.
T- 7 Same as T-8, is used only when carbon gets very high (0.28—0.32). When carbon is above these limits use T-6.
T- 8 Drive shaft of floating type axles and all places where pure torsion is to be resisted.



Ball Bearing Testing Machine which runs with Load at any speed — FIG 4

T- 9 Steering knuckles, steering arms, front and rear axles, spring chairs.
T-10 Same as T-9.
T-13 Cap screws, truss rods, Z bars. Don't use this treatment if composition of metal is not known, as it is dangerous.
T-14 Clutch drivers, steel clutch plates, etc.

Note.—Never quench semi-floating type axle drive shafts in brine.

NOTES ON MATERIAL

H. R.—Hot rolled. Steel as it comes from the rolls in the unannealed condition, runs —.005 and generally is oversized.

A.—Annealed. Hot rolled steel annealed.

C. D.—Cold drawn. Steel either cold rolled or cold drawn into bars, from 1" to 3". Round is correct to —.00025 less than 1" round comes with .00025.

Drill Rod.—Comes polished or unpolished (Lime finished); the unpolished is more accurate. If it is wished to harden the outside of drill rod, manufacturer should have specifications to that effect.

Drop Forgings.—Billets for drop forgings must be clean, free from seams, pickled and cleaned in order to avoid cracks and seams. Should be annealed thoroughly before machining is begun.

Keys.—Stock for keys should be oil or water-harden 0.80 carbon. Steel of a high grade. Harden in oil or water at 125° F.

Aluminum No. 3.—Zinc over 14% in this makes it very brittle. Heat of pouring also affects the brittleness. High zinc gives metal with very good casting qualities.

Aluminum Alloy.—Should be specified not by number but by percentage of each metal required. Then buy each metal pure and mix.

STANDARD SPECIFICATIONS—GENERAL NOTES

Cap Screws, Studs and Nuts—These are to be of C S No. 3 or A. L. A. M. standard screw stock, preferably the latter, except where N S No. 1 is specified.

Crank Shafts—In general the material specified will be N S No. 1, but the final choice of material and also its treatment is to be left to the Drop Forge people.

Tubing—Unless otherwise specified all tubing is to be cold drawn and is to be medium anneal or temper.

Gauges—Unless otherwise specified, where material is commercially gauged decimal equivalent only will be given, gauge and name of gauge being omitted.

Bar Steel—This material comes from the mills in one of three different conditions, which conditions will be specified as follows;
H R—Hot Rolled—Bar steel as it comes from the rolls in the unannealed condition. Runs +.005 and is usually oversize.
A—Annealed—Hot rolled bar steel annealed
C D—Cold Drawn—Hot rolled bar steel annealed and cold rolled or drawn to size. 1" to 3" round, runs +.0005, less than 1" runs +.00025.
Drill Rod—Comes from mills either polished or unpolished, the latter being the more accurate.
Drop Forgings—Billets for drop forgings must be free from seams, pickled, cleaned and inspected before use. Forgings must be thoroughly annealed before machining.
Key Stock—Stock for special keys should be high grade .80% carbon steel. Hardening to be done in oil or water at 125° F.

After Material Comes the Finished Product—When the material is being worked up in the shop, it is necessary to do more than place reliance upon the supervising influence of the laboratory over the purchasing department. In the working up of the material into parts, each operation is inspected, and, if the workman makes no mistake in dimensioning, the material is given a critical examination to assure that no flaws were uncovered. This may look like too much of a good thing, but it reduces the size of the repair shop to insignificance, and enables the company is build more cars.

Upon the completion of the respective units, they have to be tested to ascertain how nearly they come to the mark set for them in the designing department, or to be able to determine what the remedy will be if the units have to be adjusted. For motor testing the electrodynamometer, as depicted in the first page illustration, is used, and, as the test progresses, the experts dispose themselves around the machine as follows:

(A) Observing the pull in pounds on the scales, which indicates the torque of the motor.
(B) With a phenendoscope strapped on the head listening for indications of mechanical imperfections, as noise or any undue interference.
(C) Manograph placed, and ready to take cards as soon as the motor is tuned up.
(D) Weighing out fuel with a set of scales on which the tank rests; taking specific gravity, as the occasion requires.
(E) Observing temperature of the water used in cooling. The amount of cooling water being measured, this enables the expert to determine the efficiency of the radiator and to tell if the motor is delivering an undue amount of heat units to the cooling water, which would be an indication of bad timing or mixture, assuming that the surface swept by flame is not in excess.
(F) The expert "B" has under observation a thermometer showing the temperature of the exhaust, and in this way a further check is held on the mixture and the timing.

The electric motor is cradled in such way that the "field" (frame) would rotate were the scales to be disconnected, and the torque of the motor is represented by the amount of the tendency of the field to rotate. The whole system is so calibrated that the horsepower can be determined for any motor tested, within the limits of the dynamometer, and the error is probably less than one percent.

The manograph cards herewith shown are offered as specimens of the work, and attention is called to the clearness with which they indicate:

(A) Compression pressure (C.P.)
(B) Back pressure (B.P.)
(C) Suction pressure (S.P.)
(D) Volumetric efficiency (V.E.)

With this class of information at hand, it is possible to investigate every cause of a loss, and, insofar as it is possible to do so, eliminate the same. The old way was to ignore back pressure, since it could be charged up to the muffler, whereas, with an equipment such as this, it is a relatively simple task to investigate the muffler and remove much of the back pressure. This is equal to adding power to the motor and reducing the weight of the power plant per horsepower; in other words, increase the weight efficiency of the power plant. The curve, Fig.

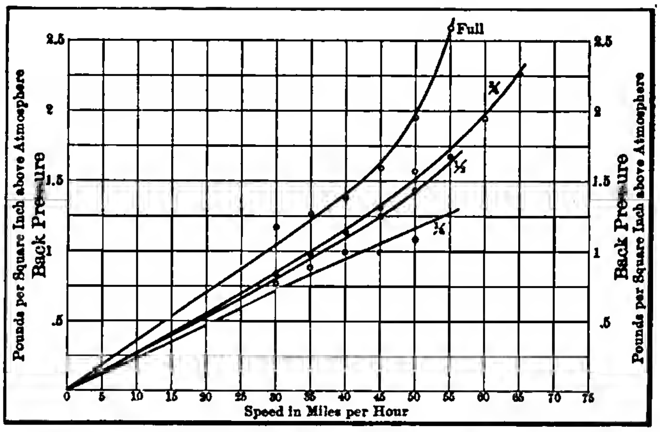

Fig. 17—Evils of back pressure are readily detected and when plotted in one specific case were seen to increase more rapidly than did the speed of the car, even when that was as high as 65 miles

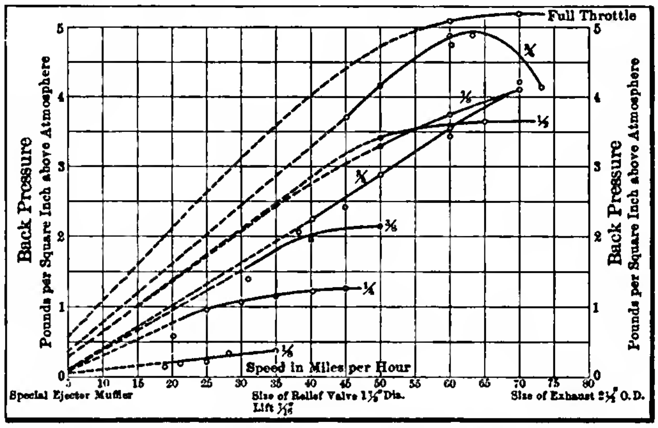

Fig. 18—Substitution of a muffler of improved and more scientific form soon eliminated the back pressure evil, at least in so far as its increase relative to the speed was concerned

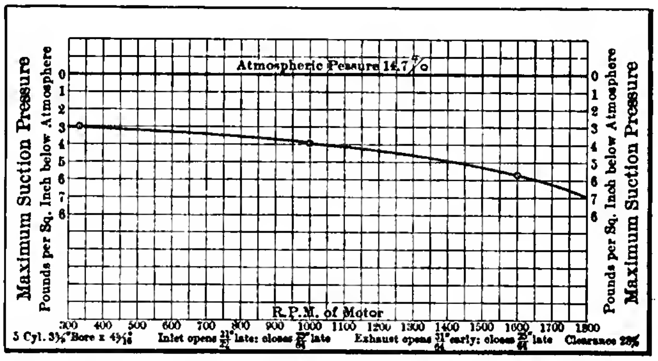

Fig. 19—Within the carbureter, back pressure or at least wire drawing made its appearance as is evidenced by the drop in the suction pressure with increased engine speed, up to 1,800 revs.

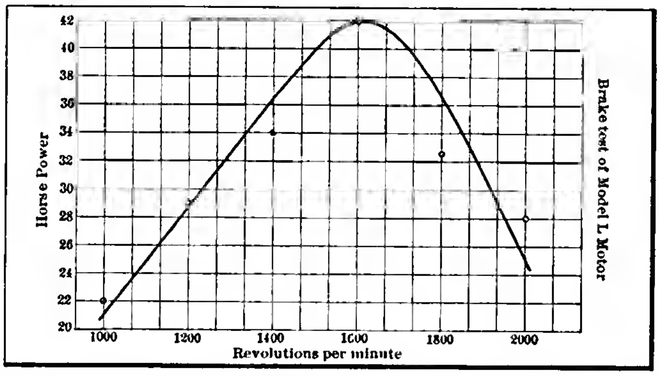

Fig. 20—Power curve of motor for which the previous indicator curves have predicted just this result, maximum power at 1,600 revolutions with a sharp rise to that point and a sharp drop beyond

20, for illustration, tells of a motor that is deficient, since the power falls off as the speed increases, after 1,600 revolutions per minute. The question is, what is the cause?

Back Pressure Due to a Defective Muffler—With a testing equipment of the character under discussion, in the hands of experts, it is possible to ascertain the cause, since the back pressure from the muffler may be determined; and Fig. 17 depicts just such a case. By inspecting the curve it will be found that the back pressure, under "full' conditions, increases more rapidly than the speed. By substituting a special form of "ejector muffler" the curve Fig. 18 resulted, in which the performance is quite different, and the power of the motor, under such conditions, would not fall off as the speed increases as a result of "piling up" of muffler pressure. The back pressure curve slopes downward at the higher range of speed, which is usually the point of greatest trouble and the one which is most difficult to cure.

Other Sources of Back Pressure Cured—It is not alone in the muffler that counter pressures will be generated; if the manifold and the piping are not ample in area, or if there are too many bends, or other eddy creating conditions, it is only by the use of proper testing equipment that there is any chance of eliminating the trouble. As an illustration of good in a rather unexpected direction, reference will be made to lowered suction pressure due to carbureter restriction, indicating excess depression. Fig. 19 shows the results of a carbureter test. In this, the suction pressure gradually increases from a minimum of three to a maximum of seven pounds per square inch, during speed changes from 300 to 1,800 revolutions per minute, thus showing a very large loss of power due solely to this cause.

Beyond back pressure, the set of curves covering practically the whole useful speed range, show as clearly as does the power curve itself the ratio of power to speed. Thus at the slowest speed of 334 revolutions, the back pressure is practically negligible; but so, too, is the power developed. With the increase in speed to 1,000, the useful end of the curve has increased, but so has the useless end, the apparent size of the two being ground for the prediction that at short speed interval further will find the turning point or peak of the power curve. This the power curve, Fig. 20, shows to be the exact state of affairs. Moreover, it shows that these cards mark to high point of the power, further increments of speed not resulting in equal increases in power. This is a condition for expert examination and preparatory to that a study of the back pressure curves, Fig. 17, will give the intelligent tester some sort of a cue to the source of trouble. The following figures show how this was remedied in one case and the immediately apparent benefits from the change.

This does not indicate that the carbureter is inferior so much as it shows that the motor demands a somewhat different set of proportions of the carbureter, and the point to be made is, that the laboratory affords a means for determining just this condition. By continuing the experiments the power obtained in the model M Thomas motor increased by gradual increment from the lowest point, which was fitted with a carburetter nozzle .040 inches in diameter, up through very noticeable increments, until the power obtained considerably exceeds the A.L.A.M. rating for a motor of this size. Fig. 16 shows the effect of changing the diameter of the nozzle alone, in a given carbureter, and the difference between the curve realized with a .040 and a .050-inch nozzle is very great indeed. The droop, which, in this instance, denoted fuel starvation, was eliminated. With the droop thus disposed of, all that remained was to correct the remaining tendencies, as excess depression, etc., and the power which ought to be available from a motor of this size was at once obtained.

In conclusion, it may not be out of place to state that the illustrations of the utility of a laboratory are but a few of the many available, and that the product of a shop can only be brought to a high state of perfection under the guidance of men who look to instruments of precision for results.

AUTOMOBILES GROW MORE LUXURIOUS

The automobile industry is a lusty infant which is nearing the strength and the buoyancy of the growing boy. Never has the present of the great industry looked as bright as now, and never has the future looked brighter.

Edwin L. Thomas

The day of the ideal automobile is here. Detail improvements will always be made, but the motor car of the present realizes the inventor's dream of the years gone by. It is dependable, and it is strong, and it is always obedient to the driver's will.

The latest efforts have been to make the motor do its work noiselessly, and to make the car as a whole smooth and quiet in operation.

Reserve power still appeals to the man with red blood in his veins, and the ability to climb hills without labor is appreciated by everyone.

Automobiles grow slightly more luxurious year by year. Cushions are made more comfortable, and the little details of design are worked out to greater perfection.

And, then, in the near future, is the vast field of business vehicle service, in which, as yet, only the taxicab has been really developed.

Regarding the entire automobile business, present and future, we are optimists.

Vice-President and General Manager
E. R. Thomas Motor Co.

THE ENGINEERING LABORATORY

Engineering departments have for their aim the production of an automobile that will stand above all others in popular esteem.

In a car of quality the American public demands grace of design and beauty of finish, silence of mechanism, and abundant power. It goes without saying that the car must be durable and sturdy, and that, in detail construction, it must represent, unit by unit, the most advanced automobile design.

Henry G. McComb

To safeguard the purchaser in every possible way an engineering laboratory was established a year ago. In this laboratory possibly the most valuable work done is the dynamometer testing of engines. This testing shows, for example, which one of a number of carbureters will give the most power, the best regulation, and the highest gasoline economy. It shows, with figures that cannot lie, the difference between a correct valve-setting and an incorrect one, and a dozen other differences between right and wrong.

In a recent test it was shown that the maximum horsepower of the motor could be increased 7.7 per cent. by a change of magneto setting, and that cutting out the muffler resulted in a 16.2 per cent. increase in power.

The aim, then, of the engineering laboratory is to test dispassionately and to decide logically. The "personal element" is more nearly eliminated. The result counts.

Chief Engineer E. R. Thomas Motor Company.

Aftermath of the Lowell Cup Race

Robertson (Simplex) Finishing a Winner in the National Stock Chassis 318-Mile Race for the Lowell Trophy

LOWELL, MASS., Sept. 11—The show is over; the tent is down; and the performers have shaken Lowell's dust from their feet. The affair was extraordinarily successful, with the automobile, of course, occuying the center of the stage.

From the all-around hustling abilities of one John O. Heinze came results gratifying to Lowell's pride and remunerative to some of its citizens, for plenteous visitors attended the diversified week of sport.

The absence of President Taft was a keen disappointment, though there was some reason in his failure to occupy the special box provided for his portly frame. Recently there has been much in print not exactly favorable to automobile competition, whereupon the President of these United States may have considered the Lowell meet one which he could afford to miss.

But the sport concluded without any real serious accident, though the unfortunate fatality that inaugurated the practice trials left a feeling of apprehension which was not entirely dissipated until the big car race had come to its conclusion.

As was prophesied by those who are supposed to know, the average speed of the winner in the big car race was lower than that made Monday by the smaller cars in Class 2. Robertson in the Simplex, who took the premier position in Wednesday's race, averaged 54.2 m. p. h., while Burman's Buick averaged 55.5 m. p. h. This, however, was not all, for Lorimer's Chalmers-Detroit, driven by Lorimer, made the first seventeen laps, 180.2 miles, Monday, in 182:24, as against Robertson's 187:55 for the same distance. This was a remarkable run, considering that the faster time was made by a 40-horsepower car, while the latter was accomplished by a 60-horsepower.

Only the first two cars averaged over fifty miles an hour. The winner covered the distance of 312 miles in 352:01 2-5, while Poole and the Isotta gained second place in 373:37 1-5 minutes, 21:35 3-5 behind, at a rate of 51.1 miles per hour.

Only five cars finished, these being, besides the above two, the Fiat, driven by Parker; Buick, guided by Burman, and the Renault, handled by Basle. Two of the Knoxes, driven by Shaw and Downey, as well as the Lozier and American, driven by Cobe and Drach, respectively, were still running when the race was called off, but were three or four laps behind the leaders.

Harry Grant, driving the Alco, certainly deserved the highest praise for the wonderful performance which he put up driving the major portion of the race. From the sixth lap to the ninth he was in third place; from the tenth to the twenty-sixth in the second, scarcely five minutes behind the Simplex. In the twenty-seventh he took first place with a lead of 3:34 over the Simplex. As he had already taken on gasoline and oil, apparently he had every chance to win. However, fate was against him, for while on the backstretch he broke one of his chains. Not being permitted to carry an extra one, he was out of the race, as a new one could not be procured soon enough to insure his getting even a position. Universal regret was expressed by those who had watched his plucky and successful fight for first place.

The winning Simplex was protested, Mr. Hollander of the Fiat company basing his objection to the fact that the car carried a couple of oil pipes to the back driving chains, and used two gasoline feed-pipes from the tank to the carbureter. The Simplex company, previous to the race, made affidavit that it had twenty-five cars of this model, fitted in like manner.

The protest meant that the technical trio, Beecroft, Edwards, and McMurtry, had to pay a visit to the Simplex factory in New York City. Its report is now in the hands of the contest board of the A. A. A.

Stock chassis racing, in order to make it positively such, is replete with difficulties requiring the exercise of some discretion by those entrusted with the carrying out of the rules—especially such rules as were experimentally drafted for the present season, but which will suffer considerable revision for next year.

It seems to be the general opinion that, instead of the old rule, which required only twenty-five cars of a particular model, in order to designate them as "stock," there must be a regulation which refers to a per cent. of the entire output of the factory. Otherwise a big concern without much difficulty can easily construct twenty-five cars of a semi-racing type, in order to obtain

Poole (Isotta) Negotiating "Dip" Which Was Considered Difficult

cars, which, in all fairness, do not belong in the stock category, and which would not be sold to the general public as such.

In the matter of drivers it is a fact that those manufacturers who entrust their racing craft to somewhat inexperienced men from the testing department do not figure very often in the list of winners. A man may be a most capable tester and still lack the essentials which go to make up a skilful racing driver. And skill only comes with practice; but the human material in the first instance must be of the sort which takes to competition as naturally as a duck does to water. Drivers are more frequently born than made, and many makers are discovering such to be the case.

Then, again, there is the driver who, having won a victory or two under most favorable conditions, begins to think himself the peer of all others. It does not take long to burst his bubble reputation, and he soon falls back among the "also rans."

Lowell is quite well satisfied with its automobile racing, and even now it hankers for something of the big sort again next year. The Lowell Automobile Club intends to seek something of a national character in 1910, and with Heinze at the helm the chances are not rated below par. This man obtained a special legislative act to permit automobile racing in Massachusetts.

Grant (Alco) in Full Flight Over a Perfect Stretch of Roadway

RANGERS' PROGRESS

Ogden, Utah, Sept. 13—This city was reached last Sunday night by the military trio carrying dispatches from Major-General Leonard Wood, of New York, to Major-General John F. Weston, of San Francisco, in the Mitchell Ranger. The party experienced road conditions which would be considered impossible in any civilized country, and they were frequently forced to obtain the permission of the Union Pacific authorities to use the railroad bridges, as all others had been swept away by washouts and swollen rivers.

Private M. E. Parrott, Tenth Regiment New York National Guard, who is in charge of the dispatches, Lieut. R. D. Rosenthal, a veteran of the Spanish War, and driver Frank X. Zirbes have condensed more novel experiences in that part of their run between Iowa and Ogden than even the New York-Paris racers encountered. All are in good health, and after rounding the corner of the Great Salt Lake look for a speedy and uneventful dash across the desert land of Nevada to Reno. From the latter place the route lies through Truckee and Colfax, and thence by a speedy schedule through Sacramento to Oakland. The goal of the first across-the-country automobile war dispatch expedition will be the Presidio, San Francisco.

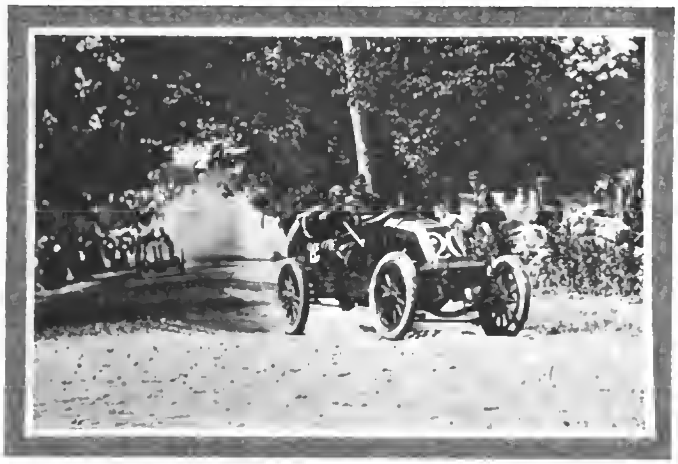
Knox Passing Over Disintegrated Backstretch

When asked after the race what he thought of the course, Robertson's reply was surprising, for the Merrimack Valley course was supposed to be ideal. "The Varnum avenue side was in good shape," said the driver, "but the backstretch was the hardest, roughest race course that I have ever driven on. Prior to the light car race it was fairly smooth, but the big cars tore up the road frightfully, and it was rough going."

GOOD ROADS TALKFEST

Herb Lytle's Apperson Which Made a Meteoric Run in the Race

Cleveland, Sept. 15—The vanguard of delegates and officers of tbe American Automobile Association are reaching Cleveland to complete arrangements for the Second Annual National Good Roads Convention which will open in this city next Tuesday afternoon. Chairman George C. Diehl of the National Convention committee and Secretary Frederick H. Elliott are already here. The official headquarters of the committee, representing the A. A. A., the National Grange, U. S. Office of Public Roads, the American Road Makers' Association, and the different automobile associations and other bodies assisting in the convention, will be at the Cleveland Automobile Club, where tbe guests, highway officials, and delegates may be assured of a hearty welcome upon tbeir arrival. As a pleasant change from the practical and more serious



Basle (Renault) Took the Turns Very Comfortably

elements of the Good Roads Convention the entertainment committee, whose members are chiefly drawn from the Cleveland Automobile Club, has made ample preparations for the social enjoyment of the delegates and guests who will be in the city during the convention days, Sept. 21 to 23. The steamer *City of Detroit* has been chartered for the use of tbe delegates and a special trip will be announced for one of the afternoons. Thursday evening a theatrical performance has been arranged which will be conducted by the members of the Hermit Club.

While the Governors of practically every State in the Union have made favorable replies to the requests that delegates be named to represent their States at the convention, no letter has exceeded in its expressions of appreciation of the good roads movement that of Governor Joseph M. Brown of Georgia. No less than fifty-four delegates have been named by Governor Brown to represent his State. Governor Brown in his letter to the officers of the A. A. A. naming the delegates says: "The improvement of the public highways being the demand of progress and necessary to that commercial and civic intercourse which makes for a quickening of patriotic endeavor, conventions that are called for the purpose of such advancement should receive executive approval."

Among the delegates, many of whom will be recognized as acknowledged good roads advocates, are: Congressman Clark Howell; Frank C. Battey, president of the Savannah Automobile Club; Asa G. Candler, president of the Atlanta Automobile Association; Prof. C. Strahan, Hon. W. F. Holdman, Hon. F. L. Seely, Hon. Wiley Williams, Gen. Clifford L. Anderson, and E. H. Inman.

OHIO FARMERS SEE HOW TO MAKE ROADS

Columbus, O., Sept. 13—The cause of good roads in tbis section of the State was given a lasting impetus by the practical demonstrations and discussions at the good roads day, held in conjunction with the State fair lately. Hundreds of automobilists and farmers participated in the exercises. One of the features was the construction of two stretches of road to illustrate the proper methods of up-to-date highway building.

American (Drach) Which Was Up and Doing When Race Concluded

JUDGE HOUGH HOLDS SELDEN PATENT IS VALID

IN the United States Circuit Court of the Southern District of New York, Justice Charles M. Hough presiding, decision was rendered on Wednesday, Sept. 15, sustaining the plaintiffs, the Electric Vehicle Company and George B. Selden, in their suit for infringement of patent claims against the Ford Motor Company, C. A. Duerr & Company, the O. J. Gude Company, John Wanamaker, et al, the Société Anonyme des Anciens Etablissements Panhard & Levassor, Andre Massenet, and Henry and A. C. Neubauer. In its decision the Court holds that the Ford machine infringes the Selden patent claims one, two, and five of the plaintiffs, and that the Panhard infringes claims one and five. The concluding paragraphs of Judge Hough's decision are as follows:

"No litigation closely resembling these cases has been shown to the Court and no instance is known to me of an idea being buried in the Patent Office until the world caught up to and passed it, and then embodied in a patent only useful for tribute. But patents are granted for inventions. The inventor may use his discovery, or he may not, but no one else can use it for 17 years. That 17 years begins whenever the United States so decrees by its patent grant. That the applicant for patent rights acquiesces in delay, or even desires delay, is immaterial to the courts so long as the statute law is not violated. On these principles complainants are entitled to a decree."

Claim No. 1, regarded as the most important, on which the court holds both the Ford and Panhard machines have infringed, is as follows: "The combination with a road-locomotive, provided with suitable running gear including a propelling wheel and steering mechanism, of a liquid hydrocarbon gas engine of the compression type, comprising one or more power cylinders, a suitable liquid fuel receptacle, a power shaft connected with and arranged to run faster than the propelling wheel, an intermediate clutch or disconnecting device and a suitable carriage body adapted to the conveyance of persons or goods, substantially as described."

Claim No. 2, of which it is held that the Ford machine only is an infringement, varies from No. 1 only in requiring the "suitable carriage body" to be "located above the engine." The fifth claim which is held to be infringed by both the Ford and Panhard sets forth substantially the same combination, but describes specifically the engine as comprising a plurality of cylinders with pistons arranged to act in succession during the rotation of the power shaft."

The complainant alleged that all three of the claims enumerated were infringed by all the defendants. "This statement of complainants' position," says Judge Hough, "seems sufficient to show that the subject matter of these suits is the modern gasolene automobile. The defendants are severally the manufacturers, seller and user of the Ford machine (a well-known American make) and the maker and importer of the Panhard, a celebrated and typical French product. If these defendants infringe, it is because complainants own a patent so fundamental and far-reaching as to cover every modern car driven by any form of petroleum vapor, and as yet commercially successful."

After entering into a detailed discussion relative to the mechanical issues at stake, Judge Hough says: "If I have correctly apprehended it, there was clearly room for a pioneer patent, and it must now be held that on its face and in view of the art Selden's is such a patent. This means that Selden is entitled to a broad range of equivalents, and this rule as applied here results in this crucial inquiry: was Selden (or anyone else) entitled in 1879 to appropriate as one of the elements of any patentable combination a 'liquid hydrocarbon gas engine of the compression type'?"

The cases in which the present decision was rendered were argued before Judge Hough for six days at the end of May and the beginning of June. In submitting the cases the record, which has been accumulating for the past five years, amounted to over 8,000 printed pages of testimony. The decison was rendered with unusual promptness. The arguments were made by William A. Redding, Samuel R. Betts and Franklin P. Fish, for the plaintiffs, and the defendants were represented by R. A. Parker, Frederick Coudert, John P. Murray and C. Benton Crisp.

R. A. Parker, of Parker & Burton, of counsel for the defendants, in a statement issued last June bearing upon the possibility of a decision, said: "As to the probable developments after the decison, it may be stated positively that if the patent is upheld we will appeal and if the patent is not upheld the plaintiffs are compelled to appeal by the contract between the A. L. A. M. and the other Selden interests. The only way this could be avoided by them would be to make a new contract and let the matter drop. At any rate, if an appeal is taken it would not get into the next court until probably a year from next October, and it would take perhaps six months in the Court of Appeals, so that perhaps it would be two years from the present before another argument would be held, and it can be seen that the patent will nearly have expired, in 1912, before the case would be settled. Should it become necessary it might even be carried to the Supreme Court."

DATE OF VANDERBILT CUP RACE IS OCTOBER 30

OCTOBER 30 is the date set by the Motor Cups Holding Company for a 1909 race for the famous Vanderbilt cup. Practically the same Nassau county course, though considerably shortened, will again be the scene of the Vanderbilt contest, which this time will be for stock car chassis racing craft.

The circuit may be less than 15 miles in length, of course utilizing the Long Island Motor Parkway to its fullest extent, and the necessary connecting State roads to complete a course.

The proper application for a sanction for the race has been forwarded to the office of the A. A. A. Contest board at Buffalo.

The race this year will be similar to last year's Motor Parkway Sweepstakes, which proved spectacular and decidedly interesting. Four classes of cars will compete simultaneously, according to classifications recommended by the general rules committee of the Manufacturers' Contest Association; the smaller cars being stopped at different shorter distances, leaving the larger ones, competing for the Vanderbilt trophy, to hold the stage for the final rounds of the competition.

The Vanderbilt Cup will be open to stock chassis in class 1 (451 to 600 cubic inches piston displacement) and class 2 (301 to 450 cubic inches), both running in one class for a distance of approximately 275 miles. Trophies will be offered for stock chassis in class 3 (231 to 300 cubic inches) at approximately 205 miles, and class 4 (161 to 230 cubic inches) at approximately 135 miles, while special trophies will be awarded to the winner in classes 1 and 2, competing in unison for the Vanderbilt Cup.

Entry blanks, now in the hands of the printers, will be mailed from the new office of the Motor Cups Holding Association, Denon Building, Mineola, L. I. Entry fee for Classes 1 and 2 will be $500 for each car; for Classes 3 and 4 $250 for each car.

A meeting of the Motor Cups Holding Association took place on Monday afternoon last, at which details of the race were acted upon, and the definitte announcement of a race authorized by W. K. Vanderbilt, Jr.

The course, as tentatively selected, is triangular in shape, with each side practically straight. The turns can be easily negotiated.

EXCELLENT PROSPECTS FOR FAIRMOUNT RACE

PHILADELPHIA, Sept. 13—The contest committee of the Quaker City Motor Club has been relieved of all but the actual running of the Fairmount Park race by a body of friends of the four local charitable institutions which have been named as beneficiaries. This body has taken the burden of looking to grandstands, parking spaces, tickets, ushers and the hundreds of smaller details off the hands of the committee and is working hard to have everything in readiness. In addition, the Q. C. M. C. has the active support of the city officials, who stand behind the club in all its arrangements, and, in fact, is a co-promoter with it. What this means in the matter of course protection and preliminary practice is manifest. The city will also take good care that the chances of accident are minimized. Last year officers were stationed every 80 feet around the eight-mile course; this year, with the assistance of the local militia, the cordon of guards will be doubled.

The Trophy That Will Be Contested For

The accommodations committee has arranged for 1000 parking spaces, distributed at the eight best points of vantage round the course. That this number will be much too small is apparent from the recent announcement that the Norristown Automobile Club and the Delaware County (Pa.) Automobile Club had each pre-empted 100 spaces, which together with the 50 already taken by the Q. C. M. C. disposes of one-quarter of the available accommodations. Similar applications are expected from many up-State, New Jersey and New York clubs. Runs to Philadelphia have already been arranged by several Pennsylvania clubs. As the race does not start till mid-day, it is possible for automobilists living within a radius of 100 miles to leave home in the morning and reach Philadelphia in ample time for the start.

Highway Commissioner William H. Brooks is personally giving his attention to the condition of the roadway. This year's course is identical with that of last year, which alone is a great testimonial in its favor. Oil wagons and steam rollers have been at work all the week, and will continue till the day of the race. The entire course will be ironed out several times by the heavy rollers; depressions will be filled up where Parkside avenue debouches into the Fifty-second street entrance, and the new cut-off road built last year will be still further widened and improved. The narrowest bit of road on the course is 20 feet wide. The exact length of the circuit is 7.8 miles, and the 25 laps called for will make a total of 195 miles.

The start and finish, as last year, will be on the South Concourse, in front of Memorial Hall, a relic of the Centennial Exposition of 1876. Repair and supply pits will be located immediately in front of the main grandstand on the South Concourse. There is naturally a great demand for parking spaces and box seats at this point, and the committee will get around the difficulties of allotment, and, incidentally, add a little to its receipts, by auctioning these choice viewpoints off to the highest bidders. The Warner Instrument Company is to erect and operate free of charge the score-board showing the positions of the first three cars which proved such a success at the Indianapolis track. An auxiliary prize of $100 cash has been hung up by G. H. Stetson for the driver of the fastest lap, and others of a similar nature are expected from local papers and business houses.

The following committees have been named by the Quaker City Motor Club to care for the details of arrangement:

Chairman—Dr. Joseph S. Neff.

Vice-chairman—Dr. Laurence F. Flick, Dr. Charles C. Hatfield, Dr. T. Mellor Tyson, Theodore M. Etting, Frank Hardart, Sr.

Treasurer—Mayor John E. Reyburn.

Secretary—Wm. F. Gleason.

Finance Committee—Dr. Laurence F. Flick, chairman; Daniel Baugh, Dr. Ward Brinton, Charles D. Burk, Louis C. Madeira, Col. Edward deV. Morrell, Joseph Walsh, James M. Wilcox.

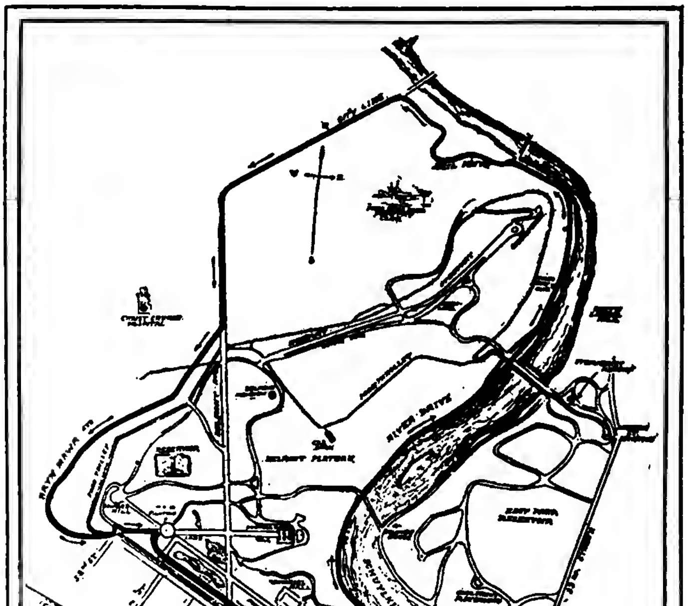
Publicity Committee—George M. Graham, "North American," chairman; Richard J. Beamish, "Evening Times"; H. L. Buckley, "Press"; John Cleary, "Inquirer"; Herbert C. Crowhurst, "Bulletin"; Harry C. Harbach, George W. B. Hicks, Richard Kain, "Record"; William M. Matos, William Rocap, "Ledger"; H. Starr Richardson, "Star"; George M. Schell, "The Automobile"; Frederick L. Weede, "Telegraph"; Clyde Woolson, "Item."

Police and Ushers Committee—Dr. J. Willoughby Irwin, chairman; Jacob H. Baltz, Samuel Castner, Jr., Frank A. Craig, Fred C. Dunlap, Dr. C. Lincoln Furbush, Arthur Folks, H. Laussat Geyelin.

Committee on Stands and Parking Places—Dr. Charles J. Hatfield, chairman; W. J. Clothier, Frank Hardart, Sr., Philip H. Johnson, William M. Ker, Robert L. Montgomery, W. D. Robinson, Edward D. Solenberger, Dr. J. Gurney Taylor, Richard C. Wood, J. R. Ludlow Gibbons.

TWO CHICAGO CLUBS IN ANNUAL BATTLE

CHICAGO, Sept. 13—The second annual reliability team match between the Chicago Automobile Club and the Chicago Athletic Association is scheduled for Thursday. There will be no technical committee examination of the cars at the completion of the match and only club members who are not affiliated in any manner with the motor car trade, are eligible to drive. N. H. Van Sicklen is captain of the Chicago Automobile Club team, and Charles T. Knisely, of the C. A. A., the same as last year.



Course of the Philadelphia Fairmount Park Race

CHICAGO MOTOR CLUB'S 1,000-MILE

Chicago, Sept. 13—Announcement was made to-day by the Chicago Motor Club that its annual reliability run this year would be held October 12, 13, 14 and 15, and that as usual it will be a 1,000-mile journey, spread over four days. The first day will carry the contestants 250 miles through Illinois, Iowa, and Wisconsin, and the night will be passed at Plattesville, Wis., returning to Chicago the second day. On the third day the run goes into Indiana, with the night stop at Indianapolis and the return made the fourth day.

On the first day the route goes through Elgin to Dubuque, Ia., and then to Plattesville, Wis., for the night. Returning the second day, the trail passes through Madison and Milwaukee back to Chicago. Going out again the third day, the way is through Joliet and Kankakee, Ill., to Crawfordsville, Ind., and from there to Indianapolis. The fourth day, coming back to Chicago, the contestants come by way of South Bend and Michigan City.

The rules have not been announced as yet, but the A. A. A. classification scheme will be followed.

One entry has been made—a Falcar, which will be driven by W. H. Pearce, who handled the car in the Indiana trophy road race, and which will be No. 1 in its class. The reliability this year goes into territory heretofore not touched by the Chicago Motor Club and the route selected covers all sorts of going. In Wisconsin many hills will be encountered, and it is expected the run will be the best of all the local organization has promoted and it has several record-breakers to its credit.

ANOTHER 24-HOUR RACE FOR BRIGHTON

New York, Sept. 14—The Motor Racing Association has announced that it will hold a 24-hour race at Brighton Beach this month. The dates have been set for Friday and Saturday of next week, September 24 and 25. The track has been materially improved since the last contest, and the surroundings have also been given attention. The oval has been resurfaced entirely and will be made as smooth and hard as possible. All the posts and fences around the infield have been removed, and the trench covered over, so that if any car runs off the track or is dangerously crowded in rounding the curves, its crew need not fear the consequences. Still more to the point of avoiding accidents is the step taken by the drivers' committee in deciding to give all operators a close examination. The committee is composed of Joseph Tracy, chairman; Guy Vaughn, and Arthur Campbell. Some criticism has been made regarding the proficiency of certain drivers nominated in recent events, and unless the ones hereafter are well known they will have to undergo a rigid inspection. The contestants will be asked to decide whether they desire a rule requiring a change of crews at least once every three hours. A system of block signals is being arranged at the entrance to the track from the paddock, to prevent a car from going upon the course when another is flying down the home stretch. At a meeting of the Motor Racing Association held to-day it was decided to admit lower-priced cars in the 24-hour race. This action resulted in the immediate entry of four Buicks, Chevrolet and Burman being named as two of the drivers. It is expected that a dozen cars will start in the race.

DE PALMA MAKES THREE NEW RECORDS

St. Paul, Minn., Sept. 11—Three new records for circular tracks were set up to-day by Ralph De Palma and his Fiat "Cyclone" in the meet on the State Fair track. In a one-mile race with Kilpatrick and his Hotchkiss De Palma lowered his own record of 0:51 flat, made on this track last year, to 0:50 4-5. He took two successive slices off the three-mile record, the first in a match race with Kilpatrick, in which he negotiated the distance in 2:38 4-5, and the second in the ten-mile race, in which he made it 2:38 flat. He won the ten-mile in the time of 8:49 3-5, another record.

ATLANTA'S SHOW SPACES DRAWN

Atlanta's National Automobile Show will have a representative display of American and foreign cars, this having been made known in the drawing for space which took place September 8 at the headquarters of the N. A. A. M., No. 7 East Forty-second street, New York City.

Under the supervision of S. A. Miles, general manager of the N. A. A. M., and Alfred Reeves, general manager of the A. M. C. M. A., the drawing proceeded with some 60 manufacturers seeking space. Naturally the main hall was apportioned to those who secured first choice, the fortunate ones including Packard, Franklin, Winton, Peerless, Pierce, Stevens, Maxwell, Mitchell, Stoddard-Dayton, Cadillac, Oldsmobile, Pope-Hartford, and Woods. In what will be known as Taft hall, which is nearly as large as the main hall, and is located on the main floor in the front part of the building, will be exhibited Rambler, White, Premier, Mora, Marion, Reo, Locomobile, Ford, and Buckeye.

On the elevated platform overlooking the main hall, there will be Marmon, Austin, Dorris, Glide, American, Jackson, Moline, National, Knox, Chalmers-Detroit, Elmore, Stearns, Pennsylvania, Hudson, Babcock, and Apperson.

Those in the main part of the building will include Autocar, Studebaker, Studebaker E-M-F, Standard, Jewel, Hupmobile, Overland, York, Selden, Speedwell, McIntyre, Brush, and Cartercar. In the basement will be located Columbus, Renault, Sultan, Streator, Fiat, Black, Interstate, Great Western, Rauch & Lang, Allen-Kingston, and Rapid commercial vehicles. The Rapid Motor Vehicle Company, Pontiac, Mich., have taken the largest space allotted to any one concern.

Members of the Motor and Accessory Manufacturers have drawn for space, but the announcement has not yet been made.

HOMER W. HEDGE VICTIM OF TYPHOID

Captain Homer W. Hedge, automobile and aeronautic enthusiast, died September 10 at his home, 31 West Eighty-fourth street, New York, of typhoid fever, after an illness lasting a week. Captain Hedge was the principal organizer and first president of the Aero Club of America, and one of the founders of the Automobile Club of America. As captain in the First Signal Corps, National Guard of New York, he had many friendly connections with men in the military service.

Born in New England forty-eight years ago, Mr. Hedge came to New York at an early age and took up advertising as his business. He was soon in business for himself, and at the time of his death was president of the Homer W. Hedge Company, advertising agents, at 366 Fifth avenue. In the fall of 1905 Captain Hedge, together with Cortlandt Field Bishop, J. C. McCay, A. Lawrence Rotch, Augustus Post, Colgate Hoyt, Charles Jerome Edwards, and Dave Hennen Morris, organized the Aero Club of America, and he was elected its president.

Captain Hedge is survived by his wife and daughter, Elizabeth. But few of his friends in the city knew of his sudden illness, and all expressed the greatest regret when the news of his death was made public.

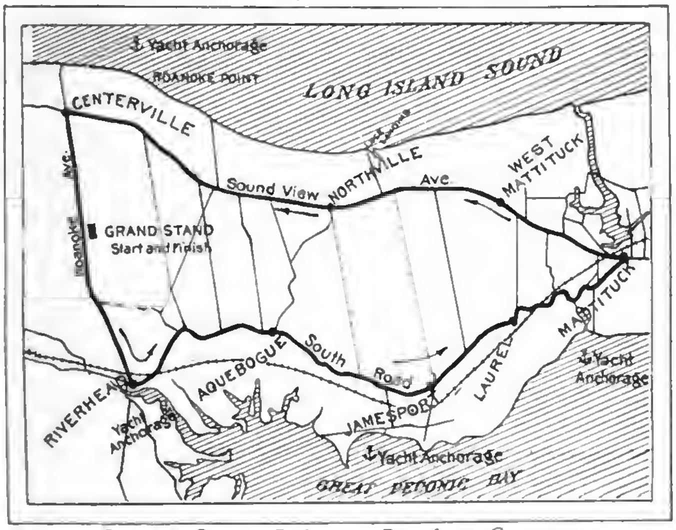
H. M. ADAMS, ROYAL SALES MANAGER

Cleveland, Sept. 11—Hobart M. Adams, long in the employ of the White Company, of this city, at the head of its Ohio sales department, has accepted the position of general sales manager for the Royal Tourist Car Company. The acquaintance of Mr. Adams with the trade extends throughout the country. His engagement with the Royal Company comes after its first season's output has been marketed, and that, too, as rapidly as manufactured. The company is the reorganized former Royal Motor Car Company, and the output of the present season, which was conservative, will be nearly doubled during the coming year, says George J. Dunham, president of the company.

Connecticut's new motor law went into effect September 1. All registrations expire December 31 of each year.

EASTERN LONG ISLAND'S STOCK CAR DERBY

On Sound View Avenue, Speed is Possible.



Map of Long Island Derby Course.

Said to be Only Dangerous Turn in Course

"LONG ISLAND'S Stock Car Derby" will take place September 29, over what is known as the Riverhead-Mattituck course. The A. A. A. stock chassis definition, of course, will govern. The Motor Contest Association, with headquarters at 1777 Broadway, is the announced promoter of the event, but all Suffolk county is engaged in the proceedings to a greater or less extent. The county's sheriff will provide the police protection of the course, assisted by scores of motorcyclists. 'Tis said that a Supreme Court judge has accepted the position of honorary referee.

Five classes will be provided for in the Derby racing, from $851 to $4,001 and over, the trophies for which will be given by Long Island towns and the Long Island railroad, besides several from other sources. In addition the participating drivers will receive one-half of the profits of the meet, providing any surplus remains.

The course is pronounced by such well-known drivers as Robertson, Strang, and De Palma, as being one of the fastest in the country. There are two stretches of nearly nine miles each, and only two towns are touched, one being little more than a village. Situated some distance from a trolley line, the crowd present will have to come mostly by automobiles and motor boats, there being four landings for the latter within a short distance of the grandstand. The course is a wide one for the most part, and runs through picturesque country. Its oiling will be done by the county, with the best of material supplied by the Standard Oil Company. The start and finish will be about three miles from Riverhead.

With practically five races in one means that there will be five finishes within an hour, as the small cars will travel 91 miles, the next class, 113 miles; third class, 136 miles; fourth class, 182 miles; and the big cars will bea sked to cover 227 miles. Predictions are that over 60 miles an hour will be the average of the big winner.

Recently at the Lowell races, W. J. Morgan, president of the Motor Contest Association of New York, and A. D. Corwin, discussed the final arrangements with Chairman Hower and other members of the Contest board. Alden McMurtry was designated as the representative of the Contest board to supervise the races, and George Robertson was named to look after the interests of the drivers.

The course is some 80 miles from New York City, which means that a comfortable half-day tour is available to those who may care to drive to the eastern end of Long Island.

SYRACUSE TRACK MEET THIS WEEK

SYRACUSE, N. Y., Sept. 13—Preparations have been completed for the third annual automobile track meet of the New York State Fair Association. This will be held on Saturday and already the entries promise the most successful event of the series. There are nine classes in all, six of which are for automobiles and three for motorcycles, including five and ten-mile races, a 50-mile, and time trials. Cash and trophies have been set up as prizes, and if any car succeeds in breaking the track record of 51 seconds, the trophy will be in money instead of a silver cup. The track is considered to be the best one-mile circuit in the country, without dust, and as hard as could be desired. The executive committee in charge of the meet is composed of H. W. Smith, M. W. Kerr, C. Arthur Benjamin, Forman Wilkinson, F. R. Bump and J. H. Valentine.

Lancastrians Who Won Third Place

Allen Sheldon and H. O. Smith

Second and First Prize Winners

FROM QUAKERTOWN TO CAPE MAY IN 50 PREMIERS

PHILADELPHIA, Sept. 13—Fifty green-and-white pennanted Premier cars left this city last Saturday morning on the first annual Cap May reliability run of the Motor Company of Philadelphia, local agent for the Premier. Leading the procession was the "Flying Squadron," composed of the three Glidden Tour Premiers, with President H. O. Smith of the Indianapolis company on board. All the cars in the run except five belonged to private owners, gathered from Philadelphia and the neighboring cities, and these had brought their wives and families with them in expectation of a day of merrymaking.

The object of the run was to equal as near as possible the time of a pathfinding car which had been secretly sent over the road in advance. The winner turned out to be B. E. Block, of Norristown, who received the silver loving cup offered by President Smith and the Premier Company. T. E. Gibberson, of Toms River, was awarded second prize, a fully equipped lunch hamper; S. N. Root, of Lancaster, got a set of Thermos bottles and a smaller hamper, and Mrs. William J. Hendren, of Philadelphia, won the ladies' prize, a silver Thermos bottle with four cups, for making the best guess of the winner's time. The figures were not announced, for the reason that auxiliary prizes had been offered to the citizens of the towns along the route guessing nearest the official time, and many of these estimates had not yet been received and tabulated.

Arrangements for the run had been progressing for the past two months, and the entire route was resplendent with gaily colored posters. Naturally the residents of the towns and villages to be passed through were on the lookout and a rousing reception was everywhere accorded the tourists. At Camden Mayor Ellis joined the party and proceeded with them to Cape May. At the latter city a committee of citizens met the tourists and complimented them on having made the journey without stragglers or accidents of any kind. Though the cars were slightly spattered with mud, every member of the party was present and enthusiastically ready for the fun.

A triumphal arch had been erected on Ocean Boulevard, and as each car passed under a gun was fired, which was responded to by the tooting of every conceivable kind of horn, siren and other noise-making device. All cars were finally parked in front of the Cape May Hotel, where preparations had been made for an elaborate dinner. Afterward the visitors attended a complimentary concert and dance of the Cape May Motor Club.

The entire party remained over until Sunday as the guests of the Premier Company, and enjoyed some fast racing on the magnificent beach in front of the hotel. The return trip Sunday afternoon was accomplished as enjoyably as the Saturday run, and likewise without mishaps. The fifty cars reached Philadelphia with full ranks, and disbanded for their homes with pleasant recollections of the trip. Every participant hopes that the promise implied in the name, the "first annual" run, will be fulfilled, and that they will have an opportunity next year to repeat their pleasant experience. In this desire, the participants are not alone, the townspeople along the route being of the same idea. The principle of interesting the towns is commendable.

Where the Cars Were Parked at the Finish in Front of the Big Hostelry at Cape May—The Cape May Hotel

Automobile Wheels, Rims and Tires

By Thos. J. Fay

BARRING the use of inferior grades of wood, and assuming that all wheels, insofar as the woodwork is concerned, should be of selected grades of second growth hickory, or equally good growths of wood, there still remains many points of detail leading to quality on a high plane, or the reverse.

In rear wheels, since the twisting moment of the motor must be transmitted to the spokes of the wheels, this torsional effort must be resisted by the wood at the miter, and if the hub-flanging is not clamped tight, it is highly improbable that the joints will be free from "working," which later condition soon leads to something worse.

Clamping Bolts Must Be Prevented from Turning—When hub-clamping bolts are tightened up, unless they are so pinned that they will not turn when the nuts are tightened up, it is difficult to apply sufficient pressure, and in the absence of this pressure the clamping effort will be insufficient. Fig. 19 depicts a hub in which the clamping bolts are provided with means for preventing the bolts from turning when the nuts are being tightened, a flattened extension, of triangular shape, just under the heads of the bolts, engages in a slot in the flange. In this hub the flange is made integral with the brake-drum, which also serves for the sprocket wheel, and the torsional effort is taken by integral metal at all points so that the woodwork is not required to labor under shock loading. As an incident attention is called to the use of a single (large) annular ball bearing in this particular case. It is because the bearing is very large that it may serve, and in some ways the scheme is commendable.

The nuts used on the hub-clamp bolts, in this example, are castellated, and in relation to this phase of detailing, it is enough to point out that it is not necessary to provide castellated nuts if the flanges do not have to be removed, which is true in almost every example of hub used in automobile work. When the nuts are not castellated, if they are screwed up tight, owing to the elastic qualities of the wood, they will stay on, although it is common shop practice to rivet over the heads to prevent them from backing off. There is no objection to this practice, although it is not necessary to mutilate the heads or nuts in the process.

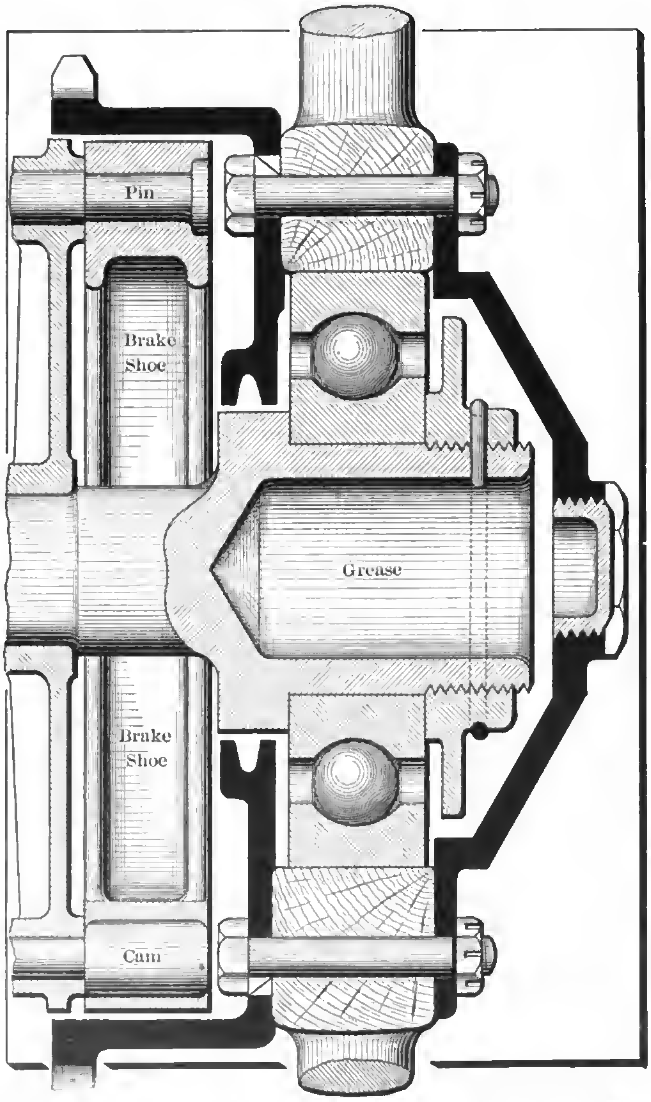


Fig. 19—Section through rear wheel with combination brake drum and inner flange

Spokes Are Made in Divers Details of Contour—A certain symmetry of contour is necessary if spokes are to be machine made, and there is positively no objection to this method of manufacture, provided the spokes are not sacrificed to the process. Fig. 20 depicts a well-made spoke, in which all the advantages known to the art of wheel making are embodied, and the depth of flanging is that which experience has dictated as adequate for the needs. This example (taken from the Thomas Model M) represents a 1910 effort, and has the benefit of much past experience. The dimensions are given so that this detail of the subject will not have to be discussed further, excepting to say that the brake-drum is bolted to the spokes in the manner as shown, which ties the drum to the spokes at a considerable radius, and without a particle of doubt, eliminates excess twisting moment on the woodwork.

The ability of a spoke, if it is well shaped, is represented by the thickness in the axle plane at the hub-flange, and in this case this dimension is 1¾ inches. The second point of importance is at A-B, at which point the major diameter is also 1¾ inches, but in the plane of the wheel, instead of, in the plane of the axle At the tenon engaging the felloe, this spoke is 1⅝ inches of the major diameter, which is in the plane of the axle, and in the plane of the wheel the minor diameter of the elliptic section is 1 3-16 inches, which dimension prevails in this plane from the point A-B out to the felloe.

In some types of spokes the section at the engagement of the felloe is round (to unit radius) and reduced gradually, to the point in the section marked A-B, rather with the expectation that the spokes will be very flexible at this point in the section, and in order to reduce the tendency of the spokes to work at the miter between the hub-flanges. The trouble with such spokes is that they are not easily fashioned by a machining process, and it is highly improbable that they will prove to be of greater flexibility than the type as here illustrated.

Fig. 21 shows a section of the wood at the miter in another type of wheel, in which the radial depth of flanging was 2¼ inches, and the axle thickness of the wood was 2⅛ inches. This wheel was used on a 60-horsepower car and worked so well, insofar as this part is concerned,

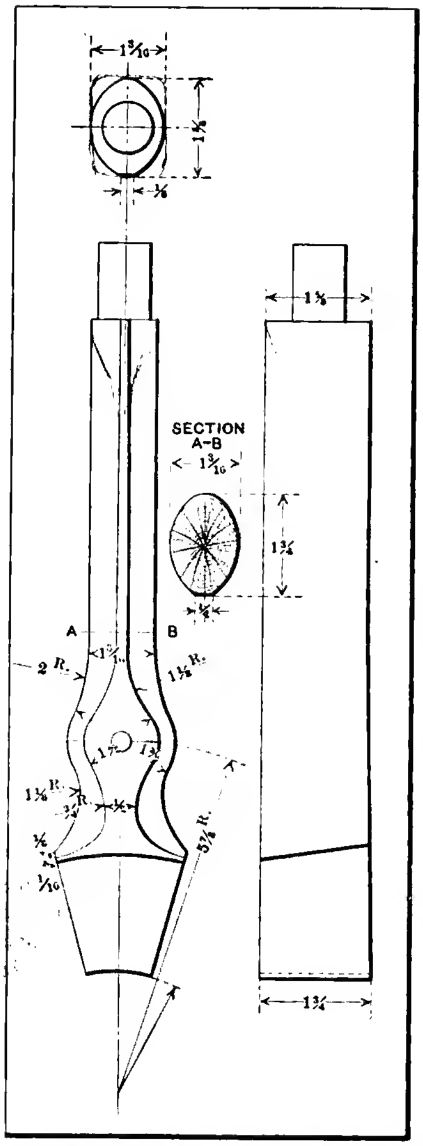

Fig. 20—Rear wheel spoke in Model M Thomas car depicting proportions, twisting, bending, and compression

that it will serve as an example of a safe depth of flanging, and also as a guide in fixing the sheer section of the spokes from the point of view of stresses induced when cars of great power skid if the wheel is not dished. Fig. 22 shows the same spoke at the tenon engaging the felloe, indicating the manner in which the spoke is wedged into the felloe, but this plan is defective unless the wedge is placed 90 degrees around from the point shown, in order to eliminate the tendency of the spoke to split the felloe. In any case it is a good plan to bolt through the felloe on both sides of the spokes in order to avoid the splitting tendency, which is accentuated when cars are driven around turns of short radius at an exceedingly high speed.

Fig. 23 depicts the Schwarz type of wheel, showing how the miter is overlapped, thus making it possible to true up the woodwork, at will, independently of the hub, and that this plan aborts the tendency of the miter to work loose, is one of the claims of the maker. They stand up well.

Advantages of Dishing Wheels—Referring to Fig. 24, it will be seen that the felloe is not in the plane of the miter, and the dish of the wheel is outward. When a car is going at a relatively high speed around a turn, the outer wheels are stressed in such a way that the tendency is to set a dish in them just reverse to the dish given by the wheel maker. The shorter the spokes are made, the greater will the dishing have to be in order to be sure that the spokes will be enough longer than the radial distance from the hub end of the spokes to the bearing against the felloe. If the spokes are longer than the radial distance from the hub to the felloe, then, when stresses are set up, tending to dish the wheel in reverse, all the spokes will serve as members in compression, and the rim on the felloe will have to do the work. As the figure shows, the excess length of spokes, marked "difference" in the figure, represents the versed sine of the angle of the spokes.

Wood is of such great strength in compression that it renders wheels practically indestructible even though the sectional area of each spoke may be reduced considerably, considering the use of from 10 to 14 spokes in each wheel. Since dishing transfers skidding stresses to the rim, inducing compression moments in the spokes, it eliminates shearing moments at the flanges of the wheels, and for this reason it is not necessary to have the spokes of very great width in the plane of the axle, near the hub. If the wheels are dished, remembering that this practice results in transferring all strains to the rim of the wheel, it is plainly indicated that the stationary rims of the wheels must be of sufficient strength to sustain under the pressure. Just what the side pressure might be under ordinary conditions is not necessary to consider, since it is possible to conceive of a case in which all the weight resting on both rear wheels might come as a lateral thrust, if the inner wheel leaves the ground, and if the outer wheel is in

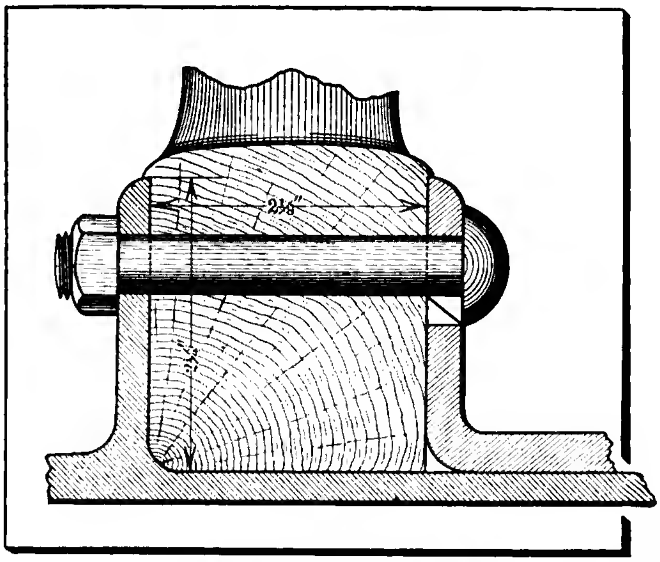

Fig. 21—Section of a hub at the miter, showing depth of flange and scheme of clamping

a rut so that it cannot skid. Taking this as a basis, it is only necessary to compute for the effect of centrifugal force of the car and involve the angle of the spokes, in order to ascertain the thrust of the spokes, tending to disrupt the rim.

Practical Details Involving the Woodwork—In automobile wheels, if the rim proper is placed over a stationary rim as it is in demountable work, the chances of wheel trouble may come, as in ordinary carriage wheels, by what is known as "rim binding." A rim-bound wheel will not give satisfaction, and if the same wheel is allowed to stand for a time in a damp place it will warp out of true, and in this warped condition it not only looks unsafe, but will be unsafe since the stresses will not then be disposed uniformly in the section of all the spokes.

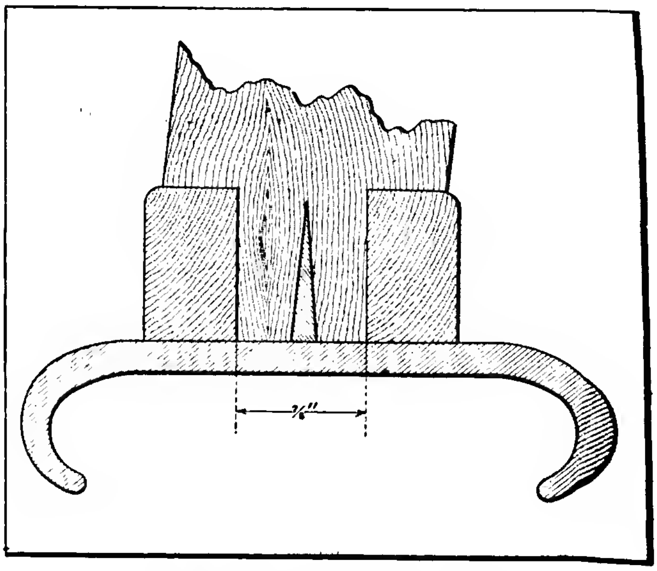

Fig. 22—Section of felloe depicting tenon and method of wedging which will split the felloe

Undue pressure of tires will spring spokes sidewise, and "bastard spokes" will have a wide influence on the results. Take a wheel, for illustration, having half of the spokes of suitable selections of second growth hickory, and the balance of "swamp" or willow hickory (this grade of hickory is soft and spongy), it will not behave like the regular (accepted) wood, and with a little pressure, wheels so made will spring out of true. Dampness will do much to engender wheel troubles of this sort, and in view of the amount of washing which automobiles naturally

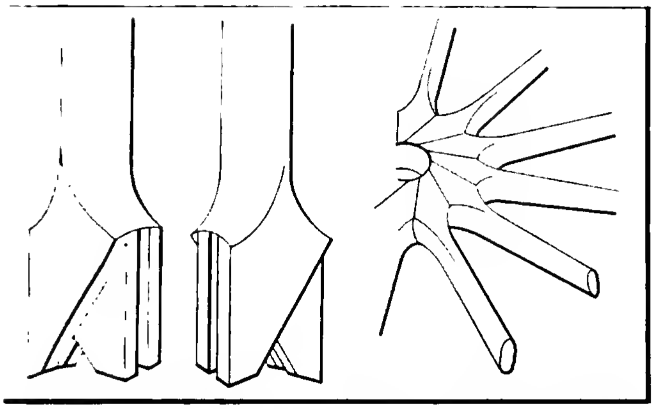

Fig. 23—In the Schwarz wheel the miter joints are made using a dovetail and tenon

fall heir to, it is of the greatest importance to select wood for wheels that will be free from bastard varieties and to put the wood through a uniform seasoning process.

So-called second growth hickory is becoming more scarce every day, and in England, for illustration, there is a growing tendency in favor of wire wheels. In America, in view of the rusting question, it is not believed that wire wheels will find favor just so long as wood holds out, and while it may be necessary to lower the standard a little in time, even so wood has not as yet reduced in quality so much that it is necessary to put up with the rust problem. True, it is barely possible that high nickel steel wire spokes may ultimately be made, in which corrosion may be practically eliminated, but it is a well established fact that merely nickel plating the metal work is not good assurance of long service without the attending rust evil. Wire wheels may be made strong enough for the purpose—of this there is no question—but wheels have to roll through water, mud and whatever else abounds in city streets, so that the rust question stands in the way, and it represents a formidable barrier to the use of wire wheels.

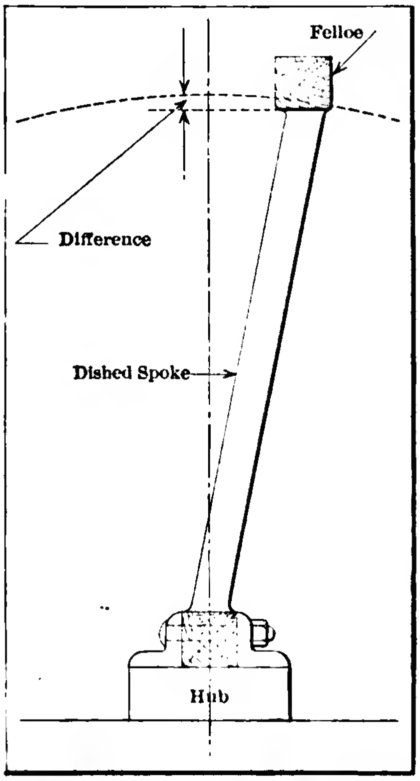

Fig. 24—Section of a wheel showing the dish, which has strength to resist skidding and lateral stresses

When a car falls into the hands of the user, unless the woodwork of the wheels is kept water-tight by persistent applications of paint, crooked wheels will be in evidence, and wheel failures will follow. It is a fair inference that many wheel failures are due to lack of paint, copious applications of water and wild driving.

Front Wheels Have But a Single Duty—When the driving is done through the rear wheels, the duty of the front wheels is limited to fixing the direction of the car, aside from the question of acting as rollers, which is common to all road wheels. Driving moments are not engendered, because there are no twisting moments of the character which must be borne by the rear wheels, and the spokes may, therefore, be reduced in section accordingly. Fig. 25 shows front wheel spoke work used in the same car as the rear spoke work shown in Fig. 20. The section A-B is slightly less (12 spokes are used in both front and rear wheels) and in the absence of the brakedown, the front wheels are somewhat more resilient. All necessary dimensions are given in the figure. A brief inspection of these two figures representing the front and rear wheel spokes as used on the same car, and that a high-powered, high-speed vehicle, will show that for assembling and other conveniences, the lateral depth has been kept at the same figure, 1 3-4 inches, while the variation to account for the differing nature of the work done by the two comes into the thickness, this being 1 3-16 inch for the hard-worked rears and but 1 inch for the fronts. While seeming a very small difference, this nevertheless is 19 per cent increase of what is really a diameter.

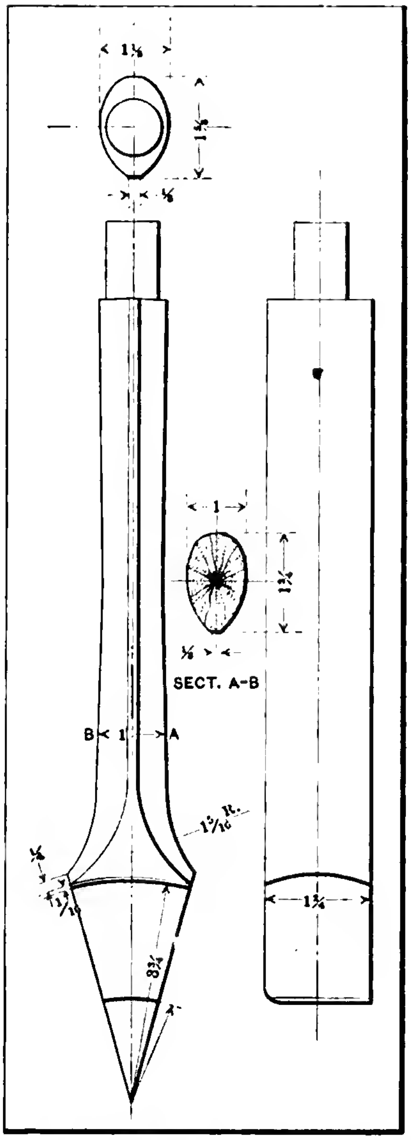

Fig. 25—Showing a front wheel spoke suitable for resilient work

(To be continued)

RELATION OF AIR TO GASOLINE

Because automobile gasoline is composed of various percentages of the several available fractions of hydrocarbon distillates, it is quite out of the question to fix upon the relative proportions of fuel to air, on an exact basis. Since, however, the average carbureter is capable of altering the ratio of air to fuel over broad ranges, it is not necessary to know the exact ratio in order to attain the best results. In the meantime, an approximation is necessary, since, in designing, and adjusting carbureters, it is well to fix upon the ratio in such a way as to have the variations allowed for, up and down, from an approximate average. The mixture becomes explosive when 10,000 volumes of air dilute one volume of gasoline. The best results follow when the relation is one volume of liquid gasoline to 8,000 volumes of air. With one of gasoline to 3,500 of air, it is non-explosive.

Some Hints on Ignition Testing

By C. Wadsworth

SINCE the life of any automobile ignition battery necessarily depends on the current-consumption of the spark coil, it is evident that if adjustments are made in conformity with the indications of current-measuring devices, the battery will last longer and all parts of the ignition system will give better service. Moreover, the installation of such instruments as a permanent part of the ignition circuit puts the operator of the car in possession of a continuous and *visible* record of performance through which faults can readily be detected and remedied under working conditions and often while the car is in actual operation.

It is well known that by adjusting the coil-vibrator or contact screw, the consumption of current can be varied within quite wide limits, reduction of the gap at the vibrator increasing the current consumption, too small a gap causing rapid depletion of the battery, as well as pitting and sticking of the vibrator points, while increasing the gap reduces the current consumption, too wide a gap lessening the flow of current to such an extent as to give rise to skipping or misfiring. It is also well known that what has been said about the gap at the vibrator points applies with equal force to the gap at the spark plug points.

Just what adjustments of the coil-vibrator and spark-plug gaps should be made in order to secure the highest degree of sparking efficiency and battery economy with a given coil may conveniently and accurately be determined by means of the apparatus shown in Fig. 1, which is made a fixed part of the battery circuit to show whether the operating conditions of the ignition system are normal or otherwise.

The device shown is a voltammeter especially designed for eliminating guess work in ignition testing under working conditions. It consists of two instruments, an ammeter and a voltmeter, mounted on a common base that is attached by screws directly to the dash if of wood, or to an insulating block in case the dash is of metal. The voltage of the primary, or battery, circuit is measured by the instrument at the right, while the strength of the current in amperes is measured by the one at the left. Both instruments operate on what is commonly known as the D'Arsonval principle, a permanent magnet being employed to create a strong magnetic field of practically unvarying intensity, within which a rectangular coil of fine wire, wound on a centrally pivoted aluminum open-frame bobbin, mounted between the pole pieces of the magnet, is made to rotate, against the opposing influence of a spring, by the current that passes through it. Attached to the coil bobbin or frame is a pointer that moves over a scale so graduated as to indicate the strength (amperage) or the pressure (voltage) of the current, causing a deflection of the swinging coil from its normal or zero position.

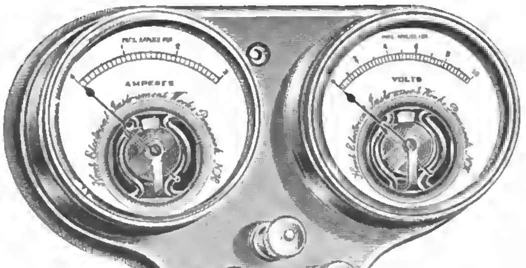

Fig. 1—Hoyt Voltammeter which simplifies ignition testing

Method of Reducing Current Losses—An extended description of the details of construction and principles of operation of the instruments would here be out of place, but attention may properly be called to the fact that by the use of a suitable resistance coil placed inside and forming part of the circuit of the voltmeter, the current loss due to its operation is reduced to a negligible factor, notwithstanding that the voltmeter is connected across the main leads of the circuit, as shown in Fig. 3, in the same manner as an incandescent electric lamp.

The ammeter is connected in series in the primary circuit, but the current is made to pass through a conductor, SH, termed a shunt, which, while of somewhat higher resistance than the rest of the circuit, is of sufficiently low resistance to make the current loss due to its use a negligible factor also. The coil of the ammeter is connected in parallel with the shunt, forming a divided circuit, a very small portion of the current passing through the coil of the ammeter and the balance through the shunt.

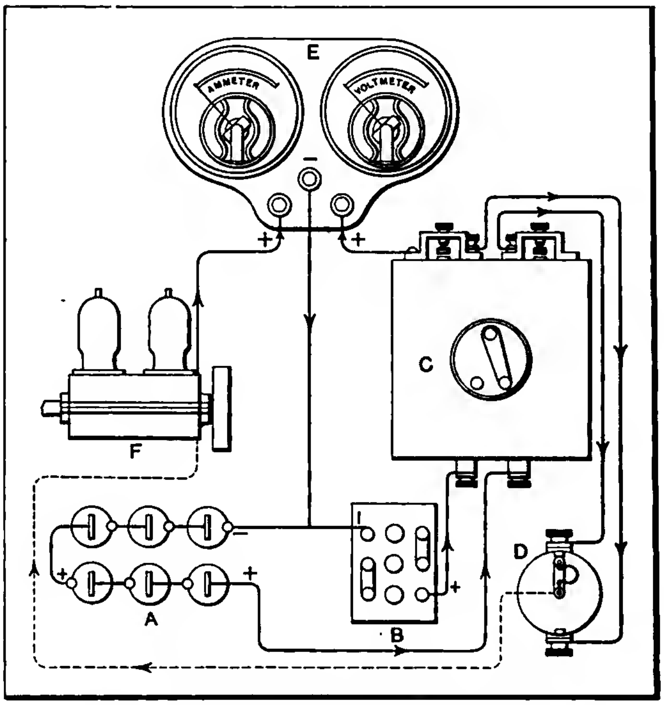

Fig. 2— Shows Method of Connecting the Voltammeter

On consulting Fig. 2, which is a conventional diagram, showing how the voltammeter is connected up, it will be seen that the carbon or positive terminal of the dry-cell battery A, and also the positive, or plus (+), terminal of the secondary, or storage, battery B, are connected to the terminals of the coil C, from which wires are led to the timer D by which the primary circuit is closed. From the contact screw of either of the coil units, a wire is led to the right-hand binding post of the voltammeter, and the zinc, or negative (—), terminals of both batteries are connected to the center or negative binding post terminal of the voltammeter, as shown, instead of to the ground, as is usual.

Current Flows Through the Primary Winding—The return-circuit wire is attached to the left-hand binding post of the voltammeter. Current from the primary battery A, or from the secondary battery B, whichever happens to be in use, passes through the primary winding of the coil C when the circuit is closed by tbe timer D. From the coil C, current flows into the voltmeter through the wire attached to the right-hand binding post, and out to the center binding post and thence back to the battery. When the timer closes the circuit through the coil a part of the current that flows through the timer ground circuit, passes into the ammeter and out to the center binding post, thence back to the battery. Most of the return current passes directly from the left-hand binding post to the center binding post through the shunt SH. The return circuit between the timer and engine in Fig. 2, and between the timer and left-hand binding post in Fig. 3, is indicated conventionally by a dotted line, the direction of current flow being shown by the arrows.

On reference to Fig. 3, it will be seen that the voltmeter V indicates the condition of the circuit regardless of whether the circuit is closed or open. This diagram also shows how the voltmeter is connected across the two main leads of the circuit beyond the switch S. If it were connected up between the switch and the batteries, it would be in circuit all the time, regardless of whether the coil switch S was open or closed, but by connecting it across the main conductors just the other side of the switch, as shown, it is in circuit only during the time that the switch S is closed.

As the timer T makes and breaks the main circuit at a point still farther on, the voltmeter indications are not affected by the operation of the timer. In other words, the voltmeter practically forms a closed circuit of very high resistance, including only that part of the battery circuit which lies between the batteries and the coil. The ammeter, however, forms a part of the main circuit beyond the coil and therefore responds to the makes and breaks of the timer, but the voltmeter does not.

Voltmeter Forms a Closed Circuit—The voltmeter circuit, when the switch S' is closed on the dry battery side, is indicated on Fig. 3 by the three-dot-and-dash line, which is intended merely to show that, as stated above, the voltmeter serves as a closed circuit in which the direction of current flow is as shown by the arrows. The current flowing from the dry battery DB, through the switch primary coil P', timer T, ground and left binding post of voltammeter, passes through the shunt SH and ammeter coil A, which is connected in parallel with the shunt, so that a pre-determined portion of the current passes through it, the balance of the current passing through the shunt. The respective resistances of the shunt and ammeter coil being known, it is an easy matter for the manufacturers to calculate the current which will pass through the combined circuit.

Ordinarily the method of wiring shown in Fig. 2 will correctly connect the instruments in circuit, but with some types of coils, as, for example, the Kingston, the wire leading to the right-hand or voltmeter binding post, must be attached to one of the hexagon nuts on the bottom of the coil box, as shown in Fig. 3, to which the same reference letters as are used in Fig. 2 are applied.

Similarly the copper or brass strip by means of which the several units of some coils are connected, may also be used, instead of the contact screw block, as a place of attachment for the wire leading to the voltmeter.

How to Proceed with the Test—In proceeding to make tests with the voltammeter, after having connected it up as indicated, the first thing to do is to make the distance between the spark-plug points as nearly uniform as possible, so that the width of the gap shall not exceed 3/100 inch and then file the platinum points of the vibrators and contact screws so as to be sure that they are perfectly flat and true as well as smooth.

For this operation, a Nicholson XF Swiss file, about number 6 cut, should be used, because the ordinary fine-cut file is too coarse and cuts away too much metal. After filing the points, the contact screws of each unit should be screwed down until the vibrator has a play of about 1/16 inch between the screw and the iron core.

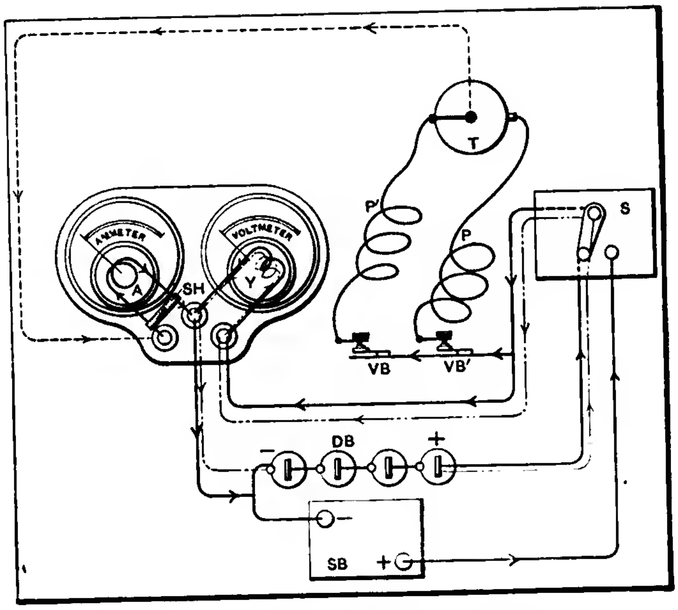

Fig. 3—Voltmeter Indicates Condition of Circuit

Then, with the gasoline supply to the carbureter shut off and compression relief cocks open, turn the engine over until the timer makes contact and sparking takes place in one of the cylinders, any one being equally good.

Note the reading of the ammeter when the timer closes the primary circuit, and if the current consumption of the coil is greater than 8/10 ampere, increase the vibrator gap by unscrewing the contact screw, and thus decrease the flow of current. Should the vibrator fail to act, however, screw down the contact screw and thus decrease the gap until the vibrator is brought into action. Proceed in the same manner to adjust each of the vibrators until the current consumption of the coil units is equal throughout their number.

In making adjustments while the engine is at rest, the circuit being closed by the timer for a considerably longer interval of time than when in actual operation, it is necessary to set them for a current consumption about twice as great as is de-

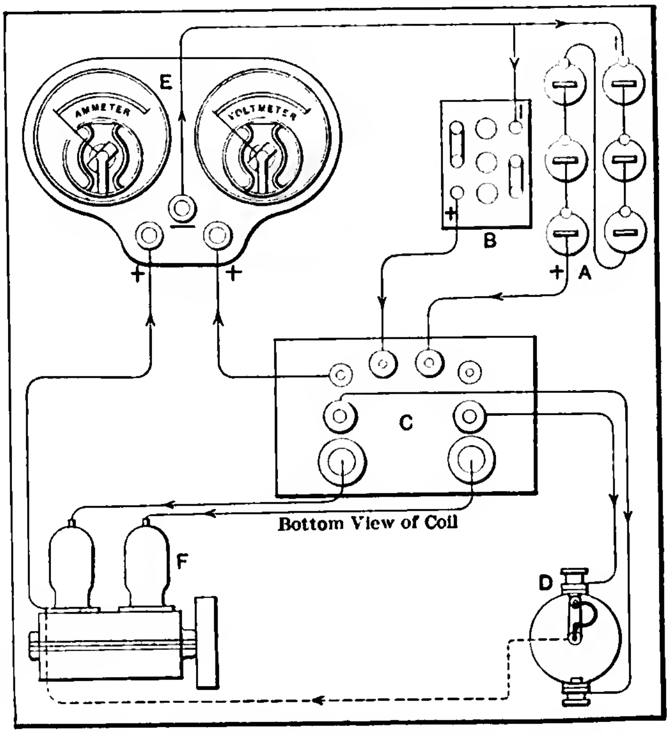

Fig. 4—Wiring Diagram, Showing Coil Binding Posts

sired, because in actual operation the flow of current through the coils is intermittent, and the ammeter needle will stand at a point representing the mean current flow. For example, a two-unit coil adjusted to take ¾ ampere would show from ⅜ to ½ ampere on the ammeter, depending on whether the period of make or period of break is the longer.

Effect of Construction on Consumption—Since the construction of a coil affects the current consumption, and wide variations in the sparking efficiency of different makes arise from differences in usage as well as construction, no definite rules can be given for the exact point at which a coil vibrator should give best results. Generally speaking, however, it may be said that a coil adjusted to operate on less than 3/10 ampere will give a thin, weak spark which would only fire a rich mixture. When adjusted to take more than 8/10 ampere, trouble will be experienced from pitting and sticking of the platinum contact points and from rapid deterioration of the battery.

With the voltammeter in circuit, observation of the normal rate of deterioration, after adjustments have been made, enables the operator to ascertain the relation between mileage and battery consumption. For instance, if a car will run 300 miles when the current consumption is such as to cause a pressure loss of ½ volt, then the car will run another 300 miles with a like drop in voltage, whether the battery is of the primary dry-cell or of the secondary storage type. Hence a glance at the voltmeter will enable the operator to judge what mileage can be obtained from the battery before it is exhausted.

Whatever may be the cause of a change that affects the battery circuit, the voltmeter gives instantaneous indication thereof, the needle or pointer remaining steady only so long as conditions are normal. With a loose contact, the needle would oscillate back and forth; with a broken wire it would not move form zero; with a poor contact due to a corroded terminal, the reading would be lower than normal; and in case one or more cells should become short-circuited, the needle would drop to an extent depending on the scale value of the cells cut out. If the pointer does not remain steady on that point of the scale representing the voltage while the car is in operation, look for the trouble at once and remedy it.

What the Ammeter Reading Signifies—The operator having also familiarized himself with the significance of the ammeter indications, a glance at it shows whether there is a normal flow of current through the coil. Any departure from normal conditions, in fact, any change in the circuit that causes a variation in the quantity or volume of current flowing through the coil, is shown and can be accounted for by the behavior of the ammeter, whose indications serve as a reliable guide in locating ignition troubles. Poor contact is shown in a diminished current flow; too small a gap between the vibrator or spark points is indicated by an abnormally high reading; and a short circuit at the spark plug, due to soot or breakage, will cause the needle to be thrown to the extreme point of its movement. A loose connection causes oscillation, while a broken wire is indicated by stoppage of the engine and zero reading of the ammeter. Study of the accompanying table will give some idea of the extent to which the voltammeter can be made of service in detecting ignition troubles.

As to the durability of the instrument when permanently attached to the car, and therefore subject to constant vibration, it may be said that a distance of more than 20,000 miles has been covered without recalibration or repairs. The cost of cleaning, adjusting, and recalibrating one of these instruments probably would never exceed $2.00. As with watches and clocks, however, to insure long life and accuracy, the instrument should be sent back to the manufacturers once a year to be checked up, or calibrated, and to have the bearings readjusted if necessary. The ordinary owner, driving his own car, should never attempt this.

TABLE OF COMMON IGNITION TROUBLES AND REMEDIES

Reading of Voltmeter	Corresponding Ammeter Reading	Cause	Remedy
Steady.....	Regular.......	Normal conditions..........	None necessary.
Oscillating needle.	Irregular......	Loose contact in battery circuit—Leakage of secondary current—Short circuit or exhausted cells.	Tighten connections—See that timer contact is made evenly—Eliminate leakage.
Uniform or gradual drop.	Regular.......	Normal deterioration of battery.	None required.
Abnormal drop.	High.........	Rapid deterioration of battery because of short circuit at plug or in battery box—Improper adjustment of coil-vibrator or spark, plug gaps, latter being too narrow—One or two exhausted cells.	Eliminate short circuit—Readjust vibrator and spark gaps—Remove exhausted cells.
Normal....	Low..........	Poor contact in timer, vibrator, or connections—Short circuiting of cells	Clean contacts, eliminating effects of corrosion or wear.
Normal....	High.........	Sooted spark plug—Gaps at vibrator or spark plug too small—Decreased coil efficiency.	Clean spark plugs—Increase width of gaps—Readjust tension of vibrator spring.
Normal....	Irregular......	Poor timer contact.........	Fix timer.
Normal....	Zero..........	Broken ground wire........	Put in new wire.
Zero.... ..	Zero..........	Broken wire between coil and battery or broken battery connections.	Put in new wire.

APPLICATION OF HEAT TO THE MIXTURE

While it is true that the rate of flow of liquid gasoline will increase with increasing temperature of the liquid, and even considering the fact that if heat is not applied to the liquid it will not vaporize, these considerations do not alter the vapor condition and the performance of the mixture in route to the motor, from the carbureter. Since automobile gasoline is a composite of several fractions of the hydrocarbon, and since all of the fractions do not hold to the same volatility, it is advantageous to prepare the mixture, in route, with the idea of affording the best results. If heat is applied to the mixture after it leaves the carbureter, the less volatile fractions will be more or less vaporized, and the performance in the combustion chamber will then be superior. It may not be possible to vaporize some of the heaviest contents, but it is fortunate, perhaps, that the percentage of such fractions is low, relative to the whole content. In the meantime, what is wanted is a means of supplying the right number of heat units, at some constant desirable temperature, rather than a limited amount of highly heated air, as is sometimes the practice. The practice of furnishing heat at the point of vaporization is also gaining in favor, daily.

WIRE-DRAWING IN CARBURETERS LIKELY

Frequently it is observed that the intake to the carbureter is so restricted that noise issues and a little further investigation in such cases will disclose, in all probability, that wire-drawing is one of the ills. It is not alone the noise that is objectionable in such cases; the power of the motor will be less, due to the restriction which has the effect of reducing the weight of mixture that enters into the cylinders, and the power of a motor is undoubtedly proportional to the weight of mixture that enters the cylinders, assuming, of course, that the same is in acceptable form and that it is completely burned. True, there must be a depression in the carbureter in order that there will be a difference in pressure, so that gasoline will be sucked into the train of air; equally true, it is of the greatest importance to have the depression as low as possible in order that the power of the motor will be a maximum. If the depression is but slight, provided the carbureter is properly designed, the amount of fuel entrained will be adequate for the purpose. If, on the other hand, the depression is very large and holds considerable fuel, it will soon be found to be wasteful of the liquid. This large depression is the base of the modern "puddle" type of vaporizer.

54 ENTRIES IN FRANCE'S COMMERCIAL VEHICLE TESTS

By W. F. BRADLEY.

PARIS, Sept. 8—Fifty-four commercial vehicles of all classes have been entered for the month's reliability tests, to commence October 15 and end November 15. The importance of the trials, which are organized by the Automobile Club of France, has been very much enhanced by the assistance of the government. There are two distinct sets of regulations for the single competition, one being drawn up by the Automobile Club of France and the other by the War Department. All vehicles fulfilling the requirements set forth by the military authorities can claim a military subsidy of a rather important nature. Any purchaser of the type of vehicle approved of in these tests can enter into an agreement with the Government whereby on presentation of his automobile once a year and an agreement to sell on prearranged terms in case of war, he can claim a subsidy of $600 on the purchase of the vehicle and $200 on each of the three following years. Thus he will receive $1,200 within a period of four years.

This is the first time such an arrangement has been made, the Government having previously encouraged commercial vehicles by giving a few prizes in the Club's competition and purchasing two or three of the most successful vehicles. The new system will be beneficial to the manufacturer because of the impetus it is likely to give to trade. Many firms that at present stick to horses will be induced to adopt mechanical traction in view of the Government subsidies. It is not surprising, therefore, that most of the fifty-four vehicles are taking part in the tests under the army regulations.

There are three distinct classes in the competition, consisting of trucks, road trains and omnibuses. The trucks are subdivided into five distinct classes, beginning with vehicles carrying from 880 to 1,320 pounds and ending with heavyweights taking more than a three-ton load. The road trains are divided into three classes for traction engines, trains having several trailers for goods, and trains having several passenger-carrying trailers. The omnibus section has also three classes of, respectively, 6 to 10 places, 11 to 20 places, and more than 20 seats.

The headquarters of the competition has been fixed at Versailles, eight miles to the west of Paris. Here a large shed has been built, capable of housing sixty automobiles, with a private box for each, electric light, telephone, central heating, etc. There is a large covered courtyard for the washing of the vehicles, and sufficient room for all of them to proceed to their private boxes without hindering or in any way handicapping the others. The large amount of fuel necessary for such a fleet of automobiles will be stored in a separate building, the roof of which is double and about one foot apart. The space between the two layers of planks is filled with sand. Thus if the building caught fire, the lower roof, on being burned, would allow the sand to fall onto the fire below. The same system has been adopted for the central hall in which the automobiles will be housed.

Commencing Monday, October 18, the commercial vehicles will make daily journeys from Versailles, through the surrounding country and home to their garage, after having covered about ninety-five miles. As the country around Versailles can provide all kinds of roads, from rough pave to perfect macadam, and from level stretches to grades of 12 per cent., everything that is necessary to test the vehicles is at hand. On October 20, however, a longer journey, in four stages, will be made to Clermont-Ferrand, in central France. After one day's exhibition, a return will be made to Versailles by stages of about 90 miles, and from then to the end of the competition the daily trips out of the once royal city will be continued.

Under the military regulations the vehicles will have to make several of the journeys in convoys, at a speed set by the officers, and with a determined distance between each unit of the procession. Fuel allowed during the contest is gasoline, benzol and carburetted alcohol, for all three of which consumption will be controlled. The final classification is based on economy of operation per ton mile and regularity of running.

The firms entered in the competition, most of them having several vehicles, are Lorraine-Dietrich, Berliet, Krieger, De Dion, Saurer, Delaugère & Clayette, Berna, Peugeot, Panhard-Levassor, Clement, Malicet & Blin, Desmarais & Morane, Schnieder, Cohendet, Vinot & Deguingand, Aries and Société Francaise de Constructions Automobile.

France's Motor Plowing Match

PARIS, Sept. 8—At present only three firms are entered for the motor plowing match to be held in conjunction with the Amiens agricultural motor exhibition at the end of this month. The firms are the Compagnie Internationale des Machines Agricoles (the International Harvester Company's products), Vermond & Quellenec and the Société Generale de Moto Culture.

The competition is intended to show the most suitable type of motor-driven plow by putting them to work under conditions that are as near as possible a reproduction of those pertaining on a farm. On each of the two days that the test lasts the motor plows must turn over, under predetermined conditions, not less than two and a half acres of land. Fuel, water and oil required for the test must be taken in advance to the field to be worked and placed in suitable vessels, which will be sealed by a member of the committee. Tanks can only be filled from these sealed cans under the supervision of the committee, the plugs being sealed up again as soon as the supply has been taken. As economy of working is the basis on which the awards will be made, these precautions are necessary.

Work will begin at 7:30 a. m. on each of the two days, will be interrupted for one hour and a half for lunch, and carried on until 4 o'clock. While in the field no one but the operators will be allowed to touch the motor plows, and no fuel can be taken out to them except under the control of the committee.

TESTS OF GAS AND ELECTRIC LIGHTS

The headlight tests conducted by the Royal Automobile Club in London afforded an excellent opportunity to compare acetylene and electric lamps, as both of these types were well represented. The entries included 23 acetylene lamps, 8 electric, one kerosene, and one oxygen-gasoline. The electric lamps had an average candle-power of 24.2, and an average current consumption of 0.88 watts per c.p.; however, one lamp, entered by Vandervell & Company, gave 33 c.p. on 22.3 watts, at the rate of 0.68 watts per c.p. The acetylene lamps averaged 20.8 c.p. on a consumption of 0.037 cu. ft. of gas per c.p.-hour. In the opinion of the judges of the test, ample illumination is afforded by a lamp of about 20 candle-power, which should be obtained on a consumption of 0.75 cu. ft. of gas (about 3 ounces of calcium carbide per hour) or 18 watts. This estimate, of course, presupposes efficient optical arrangements. Two headlights, two side lamps and a tail-light could therefore be run on rather less than 60 watts, which, allowing an efficiency of 75 per cent. for the dynamo, would take but one-tenth of one horsepower. A 6-volt, 60-amper-hour storage battery would run such a set of lights for six hours on one charging. The summary of the tests showed that with a given lamp the best results were obtained when the lamp was placed at a height of either two feet or seven and a half feet (as when on the roof of a closed car). When the lamp was placed at a height of three or four feet, a downward inclination made the dazzle worse. The worst of all positions tested was that with a height of five feet and no inclination; with the lamp in question the object was visible only at 22 feet. With the same lamp at a height of two feet and inclined five degrees downward, the same object was visible at 64 feet, the superior range being due to lessened height.

VULCANIZERS—THEIR WORK

Editor THE AUTOMOBILE:

[2,013]—Will you give me some information on the process of vulcanization? Are any of the gasoline vulcanizers practical for an automobile owner to use? Also, in the matter of acid (what acid?) cure, is this, in any way, injurious to the tire, and if so, to what extent? Is it a practical thing for an outside shoe? In fact, any information whereby automobile tire troubles may be lessened or remedied will be very welcome.

Nichols, Conn. W. T. K.

The process of preparing rubber to be used in the form of tires is not a long one, nor is it complicated, consisting of but a few steps. The crude rubber is cleaned, sulphur added to it and then baked into a unit by the application of heat. The cleaning process is called curing, and it is in this part that the acid is used. A rather long extract from the description of the whole process is given below. This, we think, explains the whole process in details sufficient for any one not a rubber expert.

Crude rubber, which is to be used for industrial purposes, is first subjected to a very thorough cleaning process. The fact that it is rendered plastic by heating, and that it retains the form given to it in this state at lower temperatures, facilitates its working. The working processes consist in cutting, rolling and kneading. The crude rubber is first laid in water for some time and is then cut by a constantly wetted, rapidly rotating circular cutter, into pieces of different sizes. The rubber chips thus obtained pass from the cutting machine between two rollers which turn at unequal speed and deliver a continuous brown-colored strip of rubber. By means of special kneading machines or masticators and rollers, the purified rubber is worked up into a homogeneous mass and is then dried. Frequently two closely spaced rollers are used, which are heated from the inside and rotated at equal speed. The main factors affecting the most important uses of rubber are the influence of temperature changes on its elasticity and its limited resistance to chemical agents. These weaknesses must be almost entirely eliminated by vulcanization; that is, the treatment of rubber with sulphur at a high temperature. This process consists in mixing rubber with from 8 to 20 per cent of sulphur, and at the same time with other desired ingredients, such as zinc sulphate, lithophone, talc, magnesia, chalk, etc. By means of rollers and kneading machines this mixture is first worked up into a homogeneous mass and is then heated. Of the admixed sulphur from 1 to 2 per cent is chemically united with the rubber, while the rest is either evaporated or remains as a mechanical admixture in the rubber.

The heating of the rubber sulphur mixture is one of the most difficult processes in rubber manufacture, as too high a temperature easily produces a horn-like substance, and if the temperature is too low, the process must be repeated. It is usual to work at between 110° to 140° C., and to continue this temperature for a time depending upon the mass worked upon. The most practical method of heating consists in the use of special steaming apparatus, cylindrical cauldrons, which are heated by steam and closed in front by a gas-tight cover. These contain inside wheeled trucks for the reception of the articles to be vulcanized. In order that there may be no change of form during the heating process the articles are placed in forms which are strewn with talc to prevent them from sticking. Heavy sheets of rubber are laid between iron plates; these layers are wound with layers of fabric on a drum. Fabric is vulcanized between heated rollers, driving belts in a heating press, etc. Instead of sulphur, sometimes other substances are used for vulcanization, such as the sulphur compounds of antimony, barium, calcium and lead. Rubber articles are given a red color by means of sulphur antimony and a white color by means of lithophone, magnesia, chalk, etc.

Another authority gives the range of vulcanizing temperature as between 130 and 150 degrees C., which is equivalent to from 266 to 302 degrees Fahrenheit. Still others specify different quantities of sulphur. Thus it is that experts agree on many of the details, but the main process as outlined above does not differ greatly.

The ordinary owner and operator of a car only uses the vulcanizing process to unite new pieces of rubber, such as patches, with the older and vulcanized, therefore different, rubber of the tire. The use of the vulcanizer is necessary to do this work in a proper manner, and one that will hold, just as if the two, the old tire and the new patch, were an integral part of one another. Aside from this, which amounts to making repairs in a proper manner, the average owner has no use for a vulcanizer nor for the process. The purchase and use of one, however, is a very desirable thing, since it enables the owner to attend to his tires at the first sign of trouble, and attend to them in a proper manner. In this way small and apparently insignificant cuts may be repaired before they grow and develop into large and unsightly wounds which may not be cured. This will result in prolonged life and increased mileage for the tires, which in turn reduces the cost of motoring per mile. This latter would be sufficient in the course of several seasons' driving to more than make up for the initial cost of the vulcanizing outfit.

GARAGE FLOOR CLEANER

Editor THE AUTOMOBILE:

[2,014]—Will you please inform me of something that I can use to clean the floor of a private garage, something that will remove oil and grease, and can be applied with the hands and not do them any harm.

New Rochelle, N. Y. B. GULLE.

A hot saturated solution of common washing soda will do very well. This can be made up in quantities and stored against future use. If this method is used, be sure to reheat it before using, the boiling point being about right. Since that will be too hot to apply with the hands, use any old broom or brush to "slosh" it around on the floor. An equally good, if not better, solution to use for this purpose is trisulphate of sodium, marketed by several chemical companies and sold at from four to five cents per pound at retail. This can be used cold and will not injure the most delicate hands: on the other hand, it will clean them very thoroughly, so that users of this solution use it for the hands as well as for the floors. This is strong, however, and may be used to remove paint.

The hands can be cleaned very thoroughly by the use of a mixture of soap powder and powdered pumice stone, the exact proportion varying with individuals, which proportion is soon determined by any one using it. For this reason the mixture, being indeterminate, it is not advisable to make up very much at one time.

GRINDING HUM OF GEARS

Editor THE AUTOMOBILE:

[2,015]—I have a * * * * * * Model F car; can you inform me through "Letters Interesting, Answered and Discussed," how I can eliminate that grinding hum from the gears? I have adjusted the differential gears both ways, but it seems to make little difference. J. C. BALL.

Kalamazoo, Mich.

This is a kind of trouble that we have never heard of as applied to this particular make of car. If it were the engine gears you might help it a little by substituting a fibre or rawhide gear for one of the intermediates, this usually sufficing to take out all humming and whirring noises.

You do not say what gears are at fault, but from the mention of the differential we suppose that you have reference to the transmission gears. Try the use of a different lubricant—that is, if you are using oil, resort to grease, and if using grease, try heavy oil. The writer has had unusual success with a combination of oil and grease for transmission gears, although none of the experts seem to think that this is right. The oil experts advocate oil at all times, while the firms making grease say that this should be used early and late, to the exclusion of everything else. It will not be possible to make the substitution spoken of above in the transmission, so you will have to look for looseness, and, failing that, experiment with oils, greases, and other lubricants until you obtain a noiseless lubricant, or one that will render your gear box noiseless.

PREFERS LIGHT OIL

Editor THE AUTOMOBILE:

[2,016]—H. L. Towle's article in your issue of August 19 contained an idea that I have always maintained, regardless of the manufacturer's instructions, to use a light oil when a transmission contains a plain bearing, and one that I find is seldom used.

Out of six Franklins that have come under my observation, one, and that the one I have been driving, have used a light oil. In fact, my transmission has never had anything heavier than Zeroline, the others using anything from dope to 600 W oil, with a result that instead of using from one to four bronze bushings inside of the main driving pinion within 10,000 miles, my car has better than 35,000 miles with practically no indications of wear at this point.

This result, I believe, would confirm the statement that "if there are plain bearings to be lubricated * * * * oil is almost invariably essential."

Billings, Mont. MURRAY B. FRENCH.

By "dope" the writer above means a mixture of oil and grease which is neither the one nor the other, being liquid at times and solid at other times. The writer has used this combination with the best of success in heavy truck transmissions, in which there were but four plain bearings on the differential, all of the transmission bearings being radial ball bearings or plain (not tapered) rollers.

WANTS HAND TIRE PUMP

Editor THE AUTOMOBILE:

[2,017]—Will you please ask some of your advertisers to give information, through the columns of "The Automobile" or "Letters Interesting, Answered and Discussed," where I can obtain a good, efficient hand air-pump that will readily put a pressure of 100 to 125 pounds into a tank in the garage, on which (the tank) a pressure gauge is permanently attached, making it possible in this way to fill a tire quickly and accurately? The value of such an outfit is in knowing exactly what the pressure is instead of guessing at it—and always guessing wrong when in a hurry. The pressure in the tank can be restored at odd times and maintained for ready use. A piece of pipe 8 or 10 inches in diameter and 10 feet long makes a good air reservoir.

Lima, O. C. F. LUFKIN.

The scheme outlined above is a good one, if any garage cared to follow it, but a much better one would be to have a power pump to fill the tank. This will not only pump the tank up quicker, and more surely, but the useless and exhausting physical labor connected with pumping against say 100 pounds pressure will be eliminated. With a power pump, there would also be no necessity to use so small a reservoir, the size in the suggested case being doubtless governed by the ability of one or several men to fill it and maintain the pressure within it at all times.

For the larger tanks, numerous makers of such outfits advertise in THE AUTOMOBILE, which statement is also true of power pumps. Since there is very little call for large-sized hand-pumps, very few of them are made or advertised. Doubtless, any one of the hand-pump makers would be glad to make up one on a special order. This would, however, be very expensive.

Another point to which attention is called in this connection is that with the power pump the garage man need not confine himself to the pressure stated above, 100 to 125 pounds, but can have from 150 to 200 pounds or higher if desired. This is worth considering with the modern tendency to larger tire sizes, which should, of course, have greater pressure. Thus, 95 pounds is recommended for a 5-inch tire; probably 110 would be about right for a 5 1-2-inch tire. At that figure, a single set of four 5 1-2-inch tires would exhaust the tank as suggested above, with pressure at 110 pounds.

CARS IN VARIOUS COUNTRIES

Editor THE AUTOMOBILE:

[2,018]—Will you please give me an approximate idea of the number of automobiles in use and the number produced in the past year in each of the following countries?

Denver, Col. R. H. HEAD.

Anything of this sort is always in the nature of a guess, except in the case of England, where it just happens that the Royal Automobile Club has compiled very complete and exact figures on this subject. France, too, can be given rather closely for a census was taken there, but as to this country and Canada it is only a very broad estimate. The figures follow:

	Total in Use	1909	Remarks
United States	200,000	80,000	Also 50,000 motor cycles
England	90,000	30,000	Also 65,000 motor cycles
Germany	21,000	5,800	Also 20,900 motor cycles
France	43,600	6,000	
Canada	3,000	500	

WINTER COOLING MEDIUM

Editor THE AUTOMOBILE:

[2,019]—Will you please advise me through "Letters Interesting Answered and Discussed," what would be the objections to using a very light oil for cooling as well as lubricating during the winter months. I have a Model T * * * * *, which is one of the early 1909 models and has a pump. Or, if you would advise against using the oil for cooling purposes, what would you advise using when the daily temperature is very low, around 30 below for weeks at a time in winter? E. W. J.

Norway, Mich.

Oil is very good for this purpose and if properly used, will raise the efficiency of the engine. To obtain this, you must select an oil which has a very low freezing point as well as one which is known to possess the peculiar quality of stiffening up very little under very low temperatures. Such an oil is marketed and sold for use with refrigerating machinery, and is known as refrigerating oil. In using oil, the supply need not be very great, that is, it is not as important as in the case of water, which is liable to steam away, in time. If for any reason, you could not obtain a proper oil, any oil picked up at random could be used, but would require a lot of care. Some prefer the use of alcohol or alcohol and glycerine. With the former a temperature of 30 below can be safely used, while the latter is more serviceable for slightly higher temperatures, minus 15 being its limit. The following table shows:

Alcohol Per cent by Weight	Freezing Point Fahr.
25	-3
30	-9
35	-16
40	-25
45	-36

GARAGE PLANS AGAIN

Editor THE AUTOMOBILE:

[2,020]—Will you please advise us whether you have published or any of your advertisers have offered plans of garages in the columns of "The Automobile."

Coatesville, Pa. C. R. & CO.

We have in preparation an article on the subject of garages, in the course of which plans of a number of private ones will be given, as was suggested in our reply to Letter 1,985 in the August 19 issue. This article will begin in an early issue and will run through several copies, all phases of the private garage being discussed.

HOW TO FIX CARBURETER

Editor THE AUTOMOBILE:

[2,021]—Will you please tell me why my two-cylinder engine, size 4 1-2 by 5, will not start on one or two crankings? I am positive that everything is all right. Occasionally it goes off on first turn and then again, under some conditions, I crank until red in the face, without results, especially in cold weather. The carbureter is a 1 1-2-inch * * * set between the two cylinders, with easy rounding curves in the pipes, on a level with the bottom of the cylinders. If I put gasoline in the priming cock, it will start on the first turn every time. The compression is good, as the valves have just been ground in. I have a 6-60 storage battery, the gasoline is 65 degree, and after starting the engine runs elegantly and has plenty of power, opening or closing the throttle making very little difference.

E. St. Louis, Ill. HARD STARTER.

From a perusal of the facts in your case, it would seem as if the trouble is in the level of the gasoline in the carbureter at starting, that is, the fuel level is such that not enough of the liquid flows into the mixing chamber in normal position. To remedy this, lower the nozzle so as to raise the level comparatively, trying 1-32 inch for a starter. This will cause more liquid to rise in the standpipe or nozzle, which will allow easier starting. To compensate for the extra fuel supplied in running, it will be necessary to allow the auxiliary air valve to open more than it does now. This, however, you will find out by trial after you have made the change in the nozzle level.

This same subject has been treated at various times in the past in different ways, and you are referred to the previous letters on the subject. These are: Letter 1876, May 13; letter 1910, June 17; letter 1940, July 15; letter 1952, July 22d.

Although there are no symptoms of trouble there, it would be well to overhaul your ignition system thoroughly at the same time.

LONG STROKES—MARINE USE

Editor THE AUTOMOBILE:

[2,022]—In the May 13 issue of "The Automobile" I noticed mention of a new French automobile engine (or, possibly, an airship engine) which had a rotary valve in the head and an unusually long stroke compared to the bore. The bore was about 4 inches and the stroke 9 1-2 inches. I would like to ask if this proportion is applicable to marine engines of the multiple cylinder type, with any prospect of success or advantage over the engine with bore and stroke more in keeping with the usual standard, say 4-inch bore and 4 to 5-inch stroke. G. W. TYRRELL.

Perth Amboy, N. J.

The use of a long stroke and the advantages appertaining thereto are available for any engine whatever, regardless of number of cylinders or purpose for which the engine is to be used. For marine use, however, it has an unusually applicable feature, that is, the long stroke motor delivers power at the slow speeds which are nearly always used in marine screws. This would eliminate gearingdown, as is necessary with a short stroke, high-speed engine, or its usual equivalent, throttling the engine, which reduces the power very materially. The latter is believed to be one of the reasons why the rating of marine engines is so small for equal bores as compared with automobile engines, that is, the makers appreciate that at the slow speeds used in marine work the engine will not deliver much power, and consequently rate them very low.

This is very apparent in the rating of any well-built marine engine, of which a single instance will suffice. One well-known maker builds among others three engines with a six-inch bore and seven-inch stroke. These are made in two cylinders, rated at 14 horsepower; four cylinders, rated at 28 horsepower, and six cylinders, rated at 42 horsepower.

With equally good material, workmanship, and construction, automobile engines of these sizes would rate according to formula at 28.8, 57.6, and 86.4 horsepower, respectively. But a manufacturer making an engine as large as any one of these would rate it higher, so that an average rating for these would be say, 33, 67, and 100 horsepower. The difference between the latter figures and the actual maker's rating for marine service is the difference between a speed of say 350 revolutions per minute, the maximum for marine use, and possibly 900 r.p.m. as the speed at which the engine might be run in an automobile, if it was desirable.

Now, these figures represent the power from an engine "more in keeping with the usual standard" as you have aptly put it. For a long stroke, which in this particular case would be anything from 9 inches up, the rated amount of power would be developed at a much slower speed, and at the rated revolutions, 350 per minute, more power would be produced. The engine in question (Anzani) had a ratio of bore to stroke of 1 to 2.56. This ratio applied to the engine in question would give it a stroke of 15.36, or to make it an even figure, 15 inches. That size of engine, 6 by 15, would deliver power more nearly like the automobile rating and accomplishment than like the ordinary marine engine, and that, too, at the speed of the marine power unit, namely, 350 revolutions per minute.

To show this matter to the lay reader in as simple a manner as possible, the accompanying curves have been plotted. This represents the imaginary curves of a six-cylinder engine for various lengths of stroke plotted upon the same ordinates as an actual power curve of a 4½ by 5½-inch engine. Six lengths of stroke are shown varying from 3½ inch up to 8½ inch all for the same 4½-inch bore. The former represents a ratio of bore to stroke of 1 to .78 and the latter, 1 to 1.89.

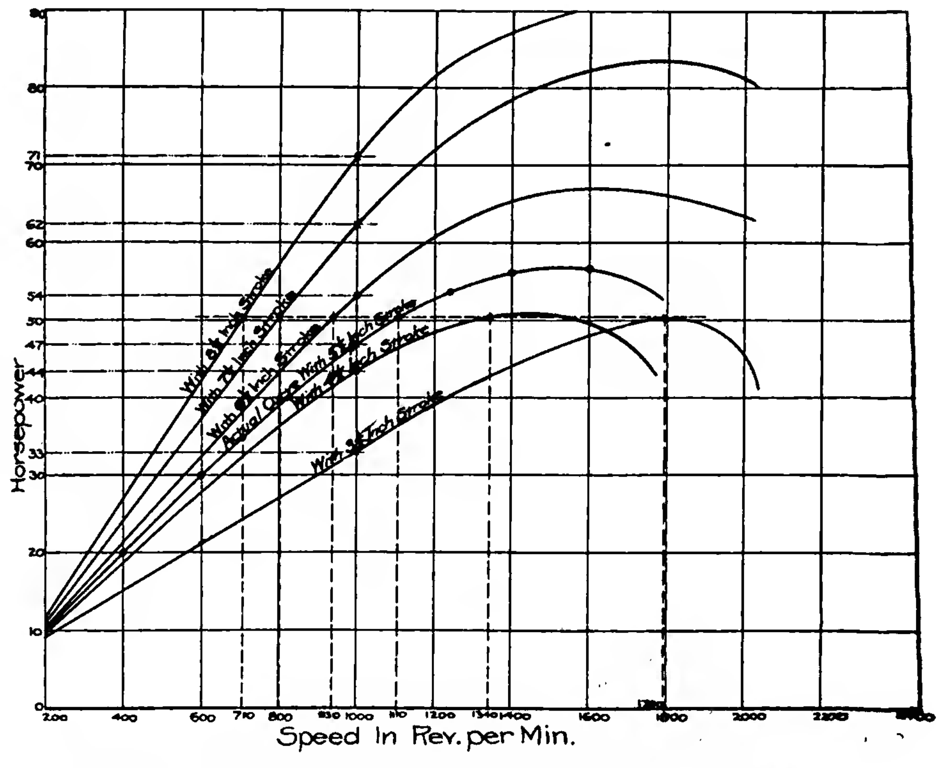
While these curves are imaginary, they are based upon accurate knowledge of what engines of the various strokes would do as exemplified in various special motors built abroad and at home. Attention is called first to the flatness of the curves of power for the shorter strokes, which gradually decreases until the line of equal bore and stroke is crossed, beyond which each curve is more steep and has less sign of a flat top or maximum point than its predecessor. Thus, the curve of the very short motor, 4½ by 3½, shows a very marked peak, at which the maximum power is developed, this being the only point at which that power is developed, the output increasing gradually but very slowly up to that point, and falling off very sharply beyond it.

With the longer strokes the falling off becomes less marked, until with the longest stroke, 4½ by 8½, there is nothing of this sort to be seen, the power increasing very markedly from the start of the test up to the maximum speed recorded, its steepness at this point being such as to lead one to the supposition that testing at a higher speed would continue to yield more and more power. Data are available for a motor of smaller bore, yet of comparatively the same ratio of bore to stroke, which continued to yield increasing power in about this ratio up to 2,400 revolutions, at which point the steepness of the curve had changed very little from that obtained at 1,500 revolutions.

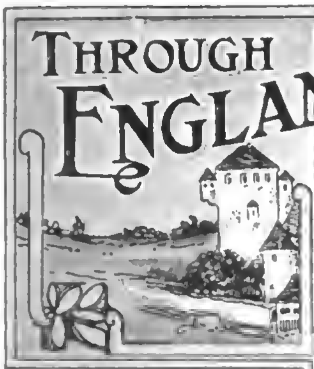
Attention is, moreover, called to the speed and power as there depicted. Thus, taking any speed at random, let us see what power will be developed at the different speeds. At, say, 1000 revolutions, the 3 1-2-inch stroke motor gives but 33 horsepower, the 4 1-2-inch stroke 44, 5 1-2-inch 47, 6 1-2-inch 54, the 7 1-2-inch 62, and the 8 1-2-inch 71. If the square motor be taken as a standard, these results mean a loss of 25 per cent in the short motor, and the following gains in the longer strokes: 5 1-2 6.8 per cent.; 6 1-2 22.7 per cent.; 7 1-2 41 per cent.; 8 1-2 61.5 per cent.

At a slower speed the differences are even more marked, as, say, 600 revolutions At this low speed, the 3 1-2 stroke develops 21, the 4 1-2 28, the 5 1-2 30, the 6 1-2 32, the 7 1-2 37, and the 8 1-2 43. In percentages these do not surpass the other figures, but considering the additional value of pulling power at slow speeds, the gain in the case of the three longer strokes of 14.3, 32.1, and 53.6 per cent. power over the square motor is of greater worth than the higher percentage of gain at the increased number of revolutions.

To compare the power output in another way, select the varying speeds at which some one power would be developed, as, say, 51 horsepower. This is only developed in the 3 1-2-inch stroke motor at the very high speed of 1,790 revolutions. Anyone could tell that in this the speed of 1,340 necessary to develop this power with a 4 1-2-inch stroke was a marked superiority. The same is true, but in a more marked degree, with the increased lengths, as exemplified by 5 1-2 1,110; 6 1-2 930; 7 1-2 805, and 8 1-2 710. To make the point more apparent, select a slightly higher power, as 52 horsepower. The two shorter stroke engines will not develop this at all, while the 5 1-2 stroke does it easily at 1,130 revolutions, the 6 1-2 at 950, the 7 1-2 at 820, and the longest stroke, 8 1-2 at 725. The selected facts and the diagram, itself, will at least afford some study, enough to more than pay for the time and work of making it. Anyone having in his possession actual and accurate tests of six-cylinder engines of this bore, 4 1-2 inches, and strokes differing from the one actual curve, 5 1-2-inch stroke, is invited to send in the figures. Or, curves based on accurate tests of four-cylinder engines, will be equally valuable and accepted as gladly.



Superimposed Power Curves of Motors with Same Bore and Varying Strokes



Through England's Heart with an American Car

By J.P.H.

To spend only a week or ten days on a motor tour of England is like rushing through the Louvre or the British Museum with catalog in hand and only stopping long enough before each picture to tick it off, and then passing on to the next, just to say one has seen it. Still, one can crowd a lot of pleasant sightseeing even into a brief period, as E. S. Partridge, of New York City, and his friends discovered when they recently made a flying tour in a 60-horsepower Stearns car.

Leaving London by the only straight road out of town—a relic, by the way, of the days when the Romans were building roads in England, and built them straight—the first place of interest is St. Albans, probably the oldest cathedral town in Great Britain. The ancient structure, restored some years ago, stands a little off the highroad, and the merest glimpse of its square tower is all that is available in passing.

Here begins the famous coaching road known as the Holyhead road, on which the Irish mails used to travel in the days when railroads were unknown. It is still a fine, smooth road, with glorious spreading meadows on both sides, dotted here and there with a field under cultivation. Through Dunstable, Towcester, Daventry, we come to Dunchurch. Coventry, the home of the British motor car—not to speak of Lady Godiva and a few other celebrities—is only a dozen miles from Dunchurch. Here the Daimler cars are made; the managing director is an American, Percy Martin, who has introduced many American methods.

The beaten track past Coventry is through Warwick and Worcestershire, otherwise "Shakespeare's Country," but, unfortunately, the imperative duty of making a call upon relatives in the city of his birth, compelled our skipper to steer the Stearns on the broad highway from Coventry to Birmingham, the Chicago of England. Two days' rest in "Brummagem" and we were once more on the wing for our flying trip through the heart of England. Heading northwest for our next destination, Nottingham, we are reminded of a bit of ancient history as we pass through Ashby de la Zouch, the scene of the famous tournament which Sir Walter Scott has immortalized in Ivanhoe. But the worst of a motor tour, especially where you want to get over a lot of country, is the way one has to skip these interesting places, even though you may make a mental reservation to come back some future day when you can stay a little longer.

Much the same conclusion was reached on leaving Nottingham, where the road passes through Sherwood Forest, an enchanting spot with the branches of the greenest trees we ever saw meeting arch fashion across the smooth gravel roadway. Visions of Robin Hood and his Merrie Men, not forgetting old Friar Tuck, seem to flit among the shadows cast by the sunshine through the waving foliage. Our next objective was Doncaster, the only town in England where they are not ashamed to own that horse racing is a profitable game. Indeed, it is said that the profit on the Doncaster racecourse, which is one of the finest in the country, pays all the local rates, poorhouses, roads, municipal government and all the rest of it except the King's taxes for the central government in London. However that may be, certainly Doncaster looks prosperous enough.

The Great North road, which used to be the connecting link between England and Scotland, leads from Doncaster north to the ancient city of York. It is a magnificent road, and like all the best roads in this country, dates back to the days of the Romans. How those old warriors built their roads, which are still as smooth as city boulevards, although their edges are covered with grass mounds, the accumulation of centuries, is a marvel. To "open 'er up and let 'er go" is only natural on such a smooth stretch as this, and we should certainly have done so but for a little warning we had shortly after leaving Doncaster, which damped our enthusiasm for some time after.

Standing by the roadside was a man with a bicycle and a yellow armlet around his sleeve. As we approached him, our guide signalled to him, and in response he threw back the lapel of his coat disclosing a red disk of about three inches diameter pinned to his vest. The performance had an air of mystery.

E.S. Partridge and J.P. Holland at Brooklands

"Police trap," exclaimed the guide, at the same time motioning to the skipper to slow down. Then he explained that the man with the red disk was one of the Automobile Association patrols or scouts. His job was to keep track of police traps. Where the road is clear he will notify passing cars that there is nothing to fear, but when there is danger ahead he shows the red disk. He had scarce finished this explanation when we saw behind a hedge two figures that looked suspiciously like plain clothes cops, and a little further along the road we came

Warwick Castle, the Ancestral Home of the Great "King Maker"

across a man in uniform who glowered at us as we passed at a fifteen mile an hour pace. The game of trapping motorists is, in some sections of this country, almost as profitable as horse racing in Doncaster.

To read English history in bricks and mortar- onc should visit Old York. Whatever induced the early settlers of Manhattan to dub their town New York is certainly a mystery, for anything more unlike the old city of that name it would be difficult to imagine. The ancient city walls, York Minster sooty with age, the old Shambles, Pettergate, Bootham Bar, and all the rest of the landmarks which centuries have left make York a museum of antiquities in which the modern street car, not to speak of our Stearns, seemed as much out of place as an ox team would be in Broadway, New York.

From Harrogate north to Bolton Abbey, one of the most picturesque ruins in England, the road was not exactly up to the standard of the great highways we had been traversing; in fact, all these old abbeys seem somehow to be sidetracked from the modern trunk highways, and, moreover, to be, many of them on the highest bit of ground for miles around. The particular peak on which Bolton Abbey stands, midway between Harrogate and Shipton, has a gradient of twenty-five per cent. in places.

Through Shipton and Settle an up and down road leads to Kendal, the front door of the Lake District. Getting into Kendal is a ticklish job by car to the man who enters for the first time, and especially if, as on this occasion, the roads be wet. Signboards by the roadside warn drivers that "This Road is Very Dangerous," meaning that unless one's brakes are in good condition the driver had better proceed gingerly on low gear. For a mile or so the winding tortuous road sinks and sinks at every yard till the foot-brake band begins to rebel at being called to act so often. Then just as you imagine you must have got to the bottom or thereabout, the road suddenly drops at a gradient suggestive of falling off a house, and before you know it you are in the narrowest, crookedest street since leaving London. This is Kendal. A mile or so of similar narrow alley, with an occasional open market place, where you pick your way among heaps of garden refuse and crowds of straggling market people, brings you on to the road for Windermere, the queen of England's lakeside resorts. Two days' rest here was altogether too brief to allow more than the fleetest glimpse of the marvelous beauties of this jewel of British scenery.

"When Knights Were Bold," one of the most amusing comedies of recent years, pictures the hero of the play suddenly awaking in the middle of the twelfth century, or, as he puts it, "seven hundred years behind the times." That is about how it felt next morning at Chester. The furniture of the hotel must have been centuries old, but one gets used to that sort of thing traveling around England. It was outdoors that we got the surprise. It had been just growing dusk when we arrived the night before and the fantastic shapes of the buildings did not particularly strike us. But coming out into the street in the clear sunny morning and suddenly finding oneself surrounded by buildings that look for all the world like the stage setting of a scene from "Henry V," well, it certainly did make us feel a bit stage-struck, if nothing worse. Even the British "Bobby," with his helmet and silver buttons, seemed a part of the show somehow. A stone's throw from the hotel was an archway crossing the street, which the "buttons" informed us was the old Town Wall. At his suggestion we investigated this relic at closer range, and found that we could ascend to the parapet by a stone stairway from the street, which we did, and had the satisfaction of walking half a mile on the old ramparts returning for breakfast at the hotel.

Conway Castle, Wales, and the Beautiful Bridge Adjoining

Then off and away from the earliest Roman camp in England, westward to Wales to the delightful watering place, Llandudno, nestling under the wall of old Conway Castle, an ideal spot for a lazy summer holiday. Thence direct south brings us into an enchanting country of woodland and valley, which grows wilder at every step until we reach a perfect fairyland of fern-covered dells, dancing waterfalls, leaping rivulets, sheltered under moss-grown trees from which hangs a drapery of verdure which resembles nothing so much as old lace. This is Bettws-y-Coed. Of course it is Welsh, and so is Llangollen (pronounced Clangothlan), where we envy the lounging holiday makers who have time to stay to admire the beauties of this wonderful valley. Still we were glad even for the all too brief peep at this scenic gem of North Wales.

The Valley of Llangollen, a Scenic Gem in Northern Wales

There is one curious feature of traveling over England which has puzzled many people, and that is, the variety of dialects encountered. To attempt anything like a description of the many varieties is a bigger job than I propose to tackle. At the same time I think one can find some explanation of the variation when hurrying over the country in a motor car and noticing how the general appearance of the land seems to be echoed as it were in the lingo of the natives. Thus from Bath down to Exeter or Plymouth the main feature of the road was the high hedges on either side, making the roadway little better than one continuous green alley, through which the hum of our wheels reverberated as though another car was following us. In the same way whenever we accosted a native in these parts his talk seemed to be full of a buzzing sound that made it most difficult to understand. I don't know if this explanation is very clear, but if it is a bit obscure then it is only in keeping with the lingo I speak of, which was simply "thick."

Of the last day's run in this flying trip I must make short work. Through Exeter, Salisbury, Basinstoke, Bagshot, and through Windsor Forest we drove, arriving at Weybridge in time for the bank holiday motor races on the Brooklands track. Here we found many old friends and a fairly enjoyable afternoon's racing. During the course of the afternoon we were introduced to Major F. Lindsay Lloyd, the manager of Brookland's track, and our best persuasion was exercised to obtain his permission for a trial run of the Stearns around the track after the race was over. He, however, declared that much as he would like to grant the permit, it was absolutely impossible.

Leaving the grounds after the race was over, however, we had to cross the wide asphalt track. One or two cars which seemed to be going around the track proved a temptation not to be resisted, and the first thing we knew the skipper had turned Stearns' nose to the left and was headed with wide-open throttle for the big bend behind the grandstand hill.

Although we were five up, she responded like a grayhound to the call. Speed? You never know what speed means till you try to find it at Brooklands. Up and up the scooped out banks we crawled sideways as our car flew ahead, and then down into the straight nearly a mile long, and once again around a curve that simply adds momentum for the next mile straight. Over sixty for the first lap! And now we are just beginning to warm up. Round the big bend once again, higher up the bank this time and we dash into the straight. The asphalt ribbon rushes under us and a double-header railway train on the track above us is passed as though it were standing still.

But when we slowed down at the gate and Major Lloyd overtook us in his little car and said what he thought about our disobeying his express injunctions—well, it took all the pride out of us, and we offered to submit to any penalty he might impose for our disobedience. Certainly, the experience was cheap at any price short of confiscating old Stearns herself. And for anyone who wants to know just what a car can do and what it feels like to get every inch of speed out of a car, the journey across the ocean is worth while if it ends at Brooklands. But I would certainly advise them to get a permit from Major Lloyd first. He is one of the most genial of good fellows, and will strain a point to oblige a visitor. But when he says "No," he means it, and the applicant had better retire gracefully.

We cannot hope to rival England's charming rural scenes or the romantic and historical interest of her cities, but we can at least hope that some one will build us a Brooklands.

Grand Stand and Starting Point of the Recent Aeronautical Tournament on the Betheny Plain, at Rheims

CHAPIN BELIEVES IN AEROPLANE AS FUTURE INDUSTRY

PARIS, Sept. 8—After touring extensively in Europe, visiting many of the French and Italian factories, and being an interested spectator at the Rheims aeroplane races, Roy D. Chapin, of the Chalmers Detroit Motor Company, left Paris for London this week with the intention of sailing for New York towards the middle of the month.

Mr. Chapin was more impressed with the aeronautical movement in France than with the progress that is being made in automobiles.

"The French have reached a settled stage," he said to THE AUTOMOBILE representative, "whereas in America we are all alive on the automobile question and are making progress daily.

Paulhan In Flight at Rheims, Just Before His Accident

"In the matter of flying machines it is different. The Rheims week was a marvelous demonstration, fully proving, if any proof were needed, that the aeroplane is not a scientific toy, nor a passing fad for wealthy and idle sportsman. Flights were made there which showed the real value of the aeroplane as a means of locomotion. I feel certain that as the result of things they saw during the flying week at least fifty Americans will become the possessors of aeroplanes during the next twelve months.

"I am not inclined to believe, however, that there is any opening for an industry for the next four or five years. At present the aeroplane is a scientific and a sporting proposition. It is not, however, sufficiently developed to be independent of the weather and state of the land over which flights are to be made. Until it gets to such a state of perfection that it can go out in any ordinary weather it is not likely to be important as an industry.

"One of the most remarkable features of the movement is the attention that has been given to lightweight motors. There were some marvelous pieces of engineering on the aeroplanes at Rheims, one of the finest pieces of work being the seven-cylinder rotary Gnome motor used by Farman and Paulhan. It appears quite likely, however, that as the aeroplane progresses the necessity for specially light motors will become less and less. At the same time this does not diminish the value of the work done towards the lightening of motors.

"I am pleased that Curtiss won the Gordon Bennett cup for America, for it will waken up the country to the importance of flying as nothing else could have done. All the Wright flights with the exception of those at Washington have been done in secret, and the only other public flights have been those made by Curtiss down East. Thus the Middle West and the West have never had an opportunity of seeing an aeroplane, and quite naturally have never had much interest in them. The winning of the cup will change all this.

"Though we have no intention of jumping into the aeroplane business immediately—it is doubtful, indeed, if any American automobile manufacturer will do so—we are keeping a close watch on the flying movement. You can be certain that when the time arrives we shall not be the last to get into the swim."

Santos-Dumont Breaks Speed Record

SAINT CYR, FRANCE, Sept. 13—Santos-Dumont to-day made a cross-country flight of eight kilometers in about five minutes. His speed was at least 90 kilometers (56 miles) an hour. The machine was a monoplane weighing but 300 pounds.

BRITAIN BECOMES KEEN ON AERONAUTICS

London, Sept. 8—The past four weeks have witnessed a surprising outburst of interest and enthusiasm in matters aeronautical throughout England. For some time there has been a growing feeling that the country was falling behind in a matter which was of supreme importance to it on account of its insular position, and this feeling has been brought to a head by the success of the recent Rheims aviation meet. Aero clubs are now in course of formation at all the important centers, and this bringing together of interested parties is bound to produce practical results in the near future.

So far, there are not more than a dozen complete aeroplanes in the country and only three or four have yet made proper flights. But of these Cody's machine must be ranked as equal to any of the foreign productions. No alterations have been made in the machine since the first successful flights three weeks ago. The latest performance was made last Saturday, when, after several passenger flights, a cross-country journey of eight miles was made. This was reliably timed to occupy 9¼ minutes, equivalent to a speed of 52 miles an hour. As the fastest performance at Rheims was the 48 mile-an-hour circuit of Bleriot, also on Saturday last, Cody seems entitled to the honor of record-holder. Doubtless an officially timed attempt will be made to decide the point.

There are several projects on foot for holding aviation meets over here, and the one most likely to materialize is that at Blackpool. The authorities of this enterprising seaside resort, noted for its motor meets in the earlier days, went as a deputation to Rheims, and, according to their report, sufficient promises of entries have been received to make success assured. Details have not yet been settled, but the date is likely to be during the second week of October, and the prizes will exceed $30,000.

The Aeroplane Club has also been endeavoring to arrange a meet at Wembley Park, only a dozen miles from the metropolis, but as a permit was never obtained or even asked from the ruling body—the Aero Club—it is unlikely that continental aviators will risk the suspension which would certainly follow their participation in an unauthorized meet.

Fortunately for the success of future meets, the Rheims contest has shown that it is not necessary to provide so extensive a track as was previously thought necessary, but that a circuit of three miles is ample. In view of this fact, the Brooklands authorities are clearing the large space within the track, and doubtless aeroplane events will soon figure on the program.

Timers' Stand and One of the Signal Poles at Rheims

Prizes for flights are becoming too numerous to mention. Some of these will serve a useful purpose, but others are impossible of realization and the action of the donors is to be deprecated. Of this nature is the prize offered by a London firm—obviously for purposes of advertisement—for the first flight across London. A twenty-mile flight across the crowded city would be accompanied by great danger to both aviator and the people below, and it is felt that steps should be taken to put a stop to these publicity dodges. Quite another thing, however, is the generous prize of $20,000 offered to the Aero Club by Baron de Forest. This is to be awarded to the aviator who flies the longest distance without a stop from any point in England to the Continent.

At the Rheims Tournament the Hospital Service and Emergency Equipment Was Complete in Minutest Detail

HOW SHALL MATERIAL BE PROVEN

With the growing importance of metals in the modern chassis has come a call for more accurate and dependable information relative to the qualities and composition of the more common metals, as well as those of the highest grade. Engineers have asked: "Of what avail is it to use and pay the price for steel of 175,000 pounds tensile strength, when in service this metal yields but the equivalent of 150,000 pounds and in other ways does not behave as well as an apparently inferior material?"

So it was that the establishment of laboratories became rather general, these being confined mostly to machines for measuring the physical qualities of the material. As time passed, it was found out, by sad experience, that the metal would not always do the work claimed for it. The first impression was that the alloy steels had been overrated, and, laboring under this delusion, many manufacturers went back to steels of simpler composition. Others, more far-sighted, asked whether they were actually getting the chemical composition for which the claims were made and for which they were paying. This necessitated the establishment of a chemical adjunct to the physical laboratory.

While this second step forward brought results, several years of service brought forth many complex problems of a different nature, resulting in the necessity for other and widely differing testing machines. This is exemplified by the torsional machine, to measure torsional or twisting ability, a quality formerly neglected. Another is the machine to apply alternations of stresses, measuring and evaluating them at the same time. In this work experimenters came in contact for the first time with the century-old work and results of Wohler and Fairbairn, which were soon shown to be in line for revision and modernization.

Thus it was that the function of the laboratory underwent a change. From the former place where much money was expended, it became a place where money was saved. This resulted in its being given a more intelligent consideration, and a more prominent place in the factory, both as to location and as to personnel. To-day the tendency, as shown in an able article on this subject elsewhere in this issue, is toward the most importance for the laboratory and its resulting work.

AUTOMOBILES DEMAND ATTENTION

Not so many years ago automobiles were regarded as presumptuous intruders on the public highways, existing only on the suffrance of the other users. In England, until the passage of the "Motor Car Act," which only recently saw its tenth anniversary, automobiles had to be driven at a speed of not more than four miles an hour, preceded by a man on foot carrying a red flag. Holland, we believe, once seriously considered excluding them altogether. The day of such annoyances is by no means past; but now the great army of automobile users need not beg humbly for scattered favors. They can ask for their rights in a way not to be neglected.

The State authorities of Massachusetts recently instituted a census of road traffic as novel in form as it was commendable. The details and figures are given elsewhere in this issue. The results of this census, although not surprising to well informed and observant travelers, will be somewhat startling to those who have not been keeping abreast of the times in this respect. Briefly, the figures show that over one-third of the road users in Massachusetts are automobilists. Nor can it be said that this proportion is exceptional. Many will be found to assert that the same would be found true in every State north of the Ohio and the Potomac and east of the Mississippi. We can hope for no better fortune than that the authorities of these States will institute censuses similar to that of Massachusetts. Then the blindest cannot deny the conclusion.

One-third forms a very respectable minority. With such a weight of numbers the automobiling public with reason can demand certain reforms for which formerly it could but petition. First among our needs is a National Highway Commission, with such powers and appropriations as will enable it to give substantial aid in the building of trunk highways, as well as guiding and directing State constructions. Then we will have uniform State laws, abolishing arbitrary speed limits and compelling all road users to carry lights at night. Finally there will come National registration. Once Utopian dreams, these benefits lie now in the automobilist's grasp if he will but use the strength of his numbers. Organization is the source of all power, and clubs will now assume even greater importance.

HALF OF MASSACHUSETTS' TRAFFIC IS MOTOR-DRIVEN

BOSTON, Sept. 13—Preliminary figures from the data acquired in the recent road census taken by the Massachusetts Highway Commission reveal the remarkable information that 45 per cent. of the traffic over the State roads is motor-driven. Though well aware that the use of automobiles over the State roads had grown very rapidly, the Highway Commission was surprised to find that it made up so large a percentage of the total use of the roads, and it is now preparing detailed data covering the entire State.

The census was taken the week of August 22 to 28, and there were established 240 stations at which a count was taken for fourteen hours each day of the week. At a few stations also a twenty-four-hour count was made. All vehicles but bicycles and motorcycles were counted, and they were divided into six divisions, four for horse-drawn vehicles and two for motor-driven. The count was also kept in two-hour periods. When the census field work was completed the commission had nearly 1,700 cards, and these are now in the hands of its clerks, who are transferring the original figures to sheets, computing totals by districts, routes, and for the State at large, figuring averages and percentages.

The work is so complicated that in only one section of the State has it begun to approach completion. This division includes Essex, Middlesex and Suffolk counties and a part of Worcester and Norfolk counties, the area being the northeast corner of the State, north of Boston and east of Worcester. In that division there were 77 observers' stations, some of which were on the main routes of automobile travel, such as those of the North Shore, to Worcester, Lowell and Lawrence.

In advance of the official compilations, Secretary A. B. Fletcher, for his own information, took a few totals from this district, and his calculations gave the remarkable total of 45 per cent. motor-driven traffic. Out of a total of 24,019 vehicles counted in this district 10,622 were automobiles, which is exactly 44.4 per cent. This percentage may not hold as strong in the central and western parts of the State, or it may run higher; no figures are yet available for the other districts.

According to Mr. Fletcher, the heaviest traveled spot on State roads in the State so far discovered is in the city of Lawrence on the State road leading to Haverhill. At this station the observer counted an average of 2,440 vehicles each day of the week of the census, and one day nearly 4,000 vehicles passed his post. The numbers ran so high that the highway commission feared an error had been made, but investigation confirmed the figures of the observer. Of the average of 2,440 vehicles a day, 820, or 33.61 per cent., were automobiles. Another very heavily traveled place, where the ratio of motor vehicles to horse-drawn was just about the reverse of that at Lawrence, was discovered near President Taft's summer home at Pride's Crossing, North Shore. On the Shore road the observer counted an average of 1,611 vehicles a day, the automobiles averaging 976, or 60.58 per cent. of the total. At Weston Center, on one of the main routes to Worcester, the average number of vehicles was 990, and 38.59 per cent. were automobiles.

Much information of great value to the commission and to everybody interested in road maintenance is sure to be derived from the census figures, which, when wholly worked out, with deductions drawn therefrom, probably will be prepared in such form that they can conveniently be distributed. Another week's census of the State roads, and also of roads in the Metropolitan park and Boston park systems will be taken next month.

Up to the first of this month motorists had paid the State of Massachusetts this year in registration and license fees the sum of $151,635.52, this sum having been received by the State Treaurer from the Highway Commission and credited to the road maintenance account.

NATIONAL GRANGE GREATLY INTERESTED IN ROADS

MEMBERS of the National Grange evince much interest in the Second Annual National Good Roads Convention to be held in Cleveland, September 21-23, and several officers of the Grange will take the platform to help along the work. Ex-Governor N. J. Bachelder, of New Hampshire, present master of the National Grange, will speak on the opening day on "The National Grange and Good Roads." He will be followed by George S. Ladd, a special good roads lecturer of the Grange, who will speak on "The New England Plan for Connecting Lines of Trunk Highways." September 22, T. C. Laylin, master of the Ohio State Grange, will speak on "The Farmers' Interest in Road Improvement," and F. N. Godfrey, master of the New York Grange, will tell of the work being done by the members of his organization and the good roads legislation in his State.

The National Grange, in conformity with the resolution adopted at its annual meeting a year ago to the effect that the Grange favors the general policy of good roads construction by the various municipalities, counties, and States, and that it also advocates the enactment of legislation by Congress making Federal appropriation for the improvement of highways, is lending its enthusiastic support to the bill recently introduced in Congress by the Hon. Frank D. Currier, of New Hampshire, providing for the creation of a National highways commission. The bill has been endorsed by the various State granges throughout the country, showing clearly the increasing interest of the farmers in good roads, and the realization of their benefits.

"The farmers recognize the need for better roads, and realize how largely such roads would contribute to their comfort and prosperity," said National Grange Master Bachelder in a recent address. "They are anxious that well considered plans for road improvement should be submitted to the State and National legislatures, and will do all in their power to aid in securing the adoption of such plans. They have made up their minds that Congress must devote a share of the annual appropriations to the construction and maintenance of our roads. National aid will not lessen local road activity. On the contrary, the roads constructed with Federal assistance will serve to stimulate everywhere the desire for better roads, and will be the means ultimately of giving the entire country a uniform system of scientifically constructed public highways."

The order of the Grange, or Patrons of Husbandry, was founded 42 years ago, and now has affiliated branches in 28 States, with a total membership of one million. The unit of the order is the local grange composed of the farmers of one community. The National Grange is the national organization composed of the masters of the State granges, each State having equal representation. The farmers of the country were virtually the first road-makers, and in many localities the work of maintaining the roads is still in their hands. One of the big features in the grange movement for good roads is the proposition for the construction by the New England States of trunk lines of highways. This subject was recently presented before the New England State governors by the State Highway Commissioner of Connecticut, James H. MacDonald, and as a result of the favorable action taken at that time plans are now under way to present the matter in a proper form before the State legislatures.

A. M. C. M. A. COMMITTEES MAKE PLANS

New York, Sept. 13—Decorative plans for transforming the Grand Central Palace into a French trellis garden were approved at the meeting of the Committee of Management last week. Inasmuch as the show this year will be the only international one it is expected to be of greater importance than ever, and the show committee, consisting of R. E. Olds, chairman; S. H. Mora, H. O. Smith, D. J. Post, and Benjamin Briscoe, is bending every effort to make it so. The exhibition will take the place of the Paris Salon, which will not be held until the fall of 1910.

In addition to considering the show plans, the committee transacted much other business of importance. S. H. Mora chairman of the membership committee, reported that four new concerns have been admitted to membership, and a number of applications will be considered at the next meeting. Charles Lewis, president of the Jackson Automobile Company, has been appointed the representative of the A. M. C. M. A. at the good roads convention of the A. A. A., to be held at Cleveland. Plans for an exposition in Berlin, Germany, of American goods were discussed, for the promoters have set aside 10,000 square feet of floor space for American automobiles and the interests of the members of the association have been placed with the show committee. The dates set are for next May, June and July.

Those present at the meeting were: H. O. Smith, Premier, chairman; C. G. Stoddard, Stoddard-Dayton, vice-chairman; S. H. Mora, Mora, treasurer; James W. Gilson, Mitchell, secretary pro tem.; W. H. VanDervoort, Moline, auditor; Benjamin Briscoe, Maxwell; R. E. Olds, Reo; Charles Lewis, Jackson; W. C. Marmon, Marmon; D. J. Post, Veeder Manufacturing Company, and Alfred Reeves, general manager.

NEW FACTORY FOR FIRESTONE COMPANY

Akron, O., Sept. 13—On a tract of ground in this city, 15 acres in extent, will soon be erected one of the largest and most complete tire factories in the world. It will be built by the Firestone Tire & Rubber Company, which has outgrown its present plant and will make it the largest concern in the world producing only rubber tires. The erection of the new buildings will show the rapid expansion of the company, for it is comparatively young in this industry. It was founded in 1900 by H. S. Firestone, but it was not until the fall of 1902 that Firestone tires were produced in a factory of their own, and that a small one-story structure in which were employed 20 men. As the product became better known the building had to be enlarged, until at present the firm occupies an immense four-story factory equipped with the best machinery obtainable, and employing 600 men. Even this has become insufficient, however, and the new plant is to be the result. Both pneumatic tires and solid ones will be manufactured as in the past, and the output will be far greater than that of any time heretofore.

ANNOUNCEMENT OF 1910 ALCO MODELS

Providence, R. I., Sept. 7—The 1910 Alco models have just been announced by the American Locomotive Company, and both the cars and their prices show noticeable changes. The Alco has now definitely abandoned the chain drive for its own system of shaft drive, in which the load-supporting member of the rear axle is a solid drop-forging. This drive has been thoroughly tested in the Alco town cars and taxicabs, in which it has been always used, and its adoption in the larger models is in no way remarkable. Another important change is the adoption of the Bosch dual system of high-tension ignition, which includes a storage battery with the magneto, although both work on the same set of plugs. The use of the battery enables the motor to be started on the spark. With these changes goes a considerable reduction of prices. Last year's three models will be continued in general in this year's 22-horsepower town car, 40-horsepower four-cylinder and 60-horsepower six-cylinder.

CHANGES IN ATLANTA TRADE CIRCLES

Atlanta, Ga., Sept. 13—The automobile map of this city has received some great changes within the last few days, through the establishment of new agencies, the moving of old ones, and the opening of new buildings. One of the most important was the formation of the Corker Motor Car Company, with the following officers: President, S. A. Corker; secretary and treasurer, E. H. Ellerby; manager of city sales, C. H. Alexander; manager of out-of-town sales, M. Z. L. Fuller, recently of the Haynes Company. The company will handle the Haynes cars for the States of Georgia, Florida, Alabama, Tennessee, North and South Carolina, and the Matheson car for this State. A commercial line will probably be added as soon as a garage can be obtained or built.

Winton cars will soon make their début to Atlanta in the handsomest show rooms for automobiles in the city. Herman Haas, the new agent, has secured one of the stores in the new Masonic Temple, where he is spending considerable money for fittings and furnishings. J. S. Goldsmith has taken the agency for the Speedwell cars, having closed a contract through S. E. Edsall, of the Speedwell factory. A location has not as yet been secured. The new Olds-Oakland Company will in a few days move to its new show rooms at 132 Peachtree street, and will have a special garage built shortly.

The new Murphy building has given space for two concerns, one the Steinhauer & Wight Company, handling the Packard, Pope-Hartford, and Cadillac; and the other, J. E. Levi & Co., the new agent for the Reo and Premier. Each concern will have two stores combined and will take possession shortly.

BUFFALO'S AUTO TRADE ACTIVITIES

Buffalo, Sept. 13—The taxicab business is making great progress. Up to the present time the E. R. Thomas Motor Company has delivered, all told, 1,942 taxicabs, and has under way some 700 of this type, with a demand quite in excess of the output.

The Pierce-Arrow Motor Car Company is fast completing preparation for the prompt delivery of 1,500 cars during the delivery season for 1910. About 1,500 men are in full swing.

The Allyne Brass Foundry Company reports deliveries from the Buffalo branch of more than a carload a week of aluminum, brass and bronze castings, mostly used in automobile work.

The Crosby Company, at its large plant, is delivering vast quantities of drawn and pressed steel to the automobile trade in the shape of hubs, covers, brake-drums, body irons, etc. The process used by the company permits the use of fine grades of steel, induces lightness with strength of parts, and from the point of view of delivery there is no process that is more conducive of results.

ONE BY ONE HORSE-CABS DISAPPEAR

Baltimore, Sept. 13—Taxicabs are fast taking the place of horse-drawn cabs in this city. The latest convert is Harry L. Stewart, who has turned his stables into a garage for taxicabs. Next week he will begin a taxicab service which will represent an investment of $80,000. As a starter 25 Alco machines will be put in commission, with more to follow if they are found necessary. The cars will have blue bodies with red wheels, and the taximeters will be driven from the front axles.

METEOR FACTORY IN CONFLAGRATION

Davenport, Ia., Sept. 10—The Meteor Car Company had a disastrous fire last night which completely destroyed its entire factory, with the exception of the office building. With the latter, however, were saved all drawings, patterns, jigs, special tools, etc., and, in fact, all necessary working material for the 1910 models. The company cannot determine how long it will be before operations are resumed, but will do everything in its power to get under way again in record time.

Rambler Eastern 1910 Test Car leaves factory — driven by G.S Patterson of Cleveland Branch

Rambler 1910 Test Car leaving factory for 5,000 mile test trip to South and Middle West

UNIQUE BUT THOROUGH ROAD TEST

KENOSHA, WIS., Sept. 13—One of the most unique methods of testing a car was pursued in the try-out of the 1910 models of Thomas B. Jeffery & Company, makers of the Rambler. The method had all of the advantages of a factory or expert test, and in addition the merit of making the various agents familiar with the new car in advance of the time, which would otherwise be the case. It consisted of sending out two of the newest additions to the Rambler family, one to the East, and the other to the South and West. These were manned by drivers from the various agencies, each crew driving on to another agency, and there turning the car over to the crew selected by the manager there. In most cases, the picked crew consisted of the manager himself.

Included in the itinerary of the eastern car were Cleveland, Toledo, Pittsburgh, Harrisburg, Philadelphia, New York, Boston, Albany, Buffalo, and back to the factory through Cleveland, Toledo and Chicago. The car traversing the West went from the factory to Chicago, South Bend, Indianapolis, Louisville, Nashville, St. Louis, Kansas City, Omaha, and thence back to the factory through Chicago, in charge of J. T. Stewart, of the Coit Automobile Company of Omaha. Not only did this method of testing the car put it up against every kind of road conditions, as, for instance, an impassable mud-hole in Kansas, which delayed it for 13 hours, but a wide experience in driving on the part of the various dealers was assured. The details of the car will be announced later on. Both cars returned to the factory in perfect condition, but it was thought wise to defer the announcement of the details until all of the agents who had driven the cars had written in and reported their widely differing experiences with the test cars.

NEWS IN GENERAL

A Party of Franklin Travelers on a Tryout of 1910 Franklin Automobiles
Photograph taken on top of Mt. Taupin, New York

Sample of Franklin Testing—On one of the recent test runs which the H. H. Franklin Manufacturing Company, of Syracuse, N. Y., is daily giving to its dealers to show the Franklin 1910 automobiles under severe road conditions there were men representing automobile interests from the Atlantic to the Pacific. In the party was H. J. Banta, Spokane, Wash.; H. R. Grant, Seattle, Wash.; J. D. Moore, Boise City, Idaho; W. S. Jewell, New York City; Robert LaPorte, Philadelphia, and Capt. Barker, of the United States Army, located at Fort Leavenworth.

The trip was down the Onondaga valley from Syracuse to Cardiff, one of the steepest hills in New York State, and about a mile in length, to Lafayette, along the ridge overlooking Onondaga valley to Tully, from Tully to Preble, where a climb up Mt. Taupin, a very steep ascent of 1,000 feet, was made. From this point the route turned to the east and went over a succession of hills varying in length and steepness, all of which were exceedingly rough and rugged until the valley of Sherburne was reached.

From there the course turned to Utica, from which point a return run was made to Syracuse. One of the cars on the trip, a 1910 six-cylinder model, here started on a record run to Syracuse, a distance of 55 miles, which it covered with its load of seven passengers in 1 hour 15 minutes, which is equal to the running time of the Fast Mail, and but ten minutes slower than the Empire State Express.

The whole demonstration was planned with the idea of putting the 1910 machines over a very severe course in order to demonstrate to the Western dealers that the cooling properties of the 1910 Franklin were beyond question of doubt.

Remy Company Plans More Branches—Owing to the great western demand for Remy magnetos the Remy Electric Company, of Anderson, Ind., manufacturer of the Remy mechanical ignition systems, has completed plans for the establishment of branch selling offices at Kansas City and San Francisco. Although locations have not been secured at this time, it is expected that a corps of experts will be in the two western marts by January 1, 1910. Edward F. Willett, who has been connected with the New York selling office, will be put in charge at San Francisco, and Ross E. Luellen will be sent from the factory to manage the Kansas City offices. These men will be assisted by experts from the factory. The expansion of the Remy Company during the season of 1909 has been marked by the establishment of branch selling offices in Chicago, New York, and Detroit, and the addition of twelve new fire-proof buildings to the factory. The increased facilities for manufacture and distribution, however, will be needed for 1910, as 80,000 Remy high-tension magnetos have been sold to automobile manufacturers on minimum specified delivery, and contracts are still being received.

Klaxon Makers Enter European Fields—The Lovell-McConnell Manufacturing Company, the maker of the famous Klaxon horns, has arranged to sell its horns in Europe as well as all over this country. With foreign patent rights it has established the Klaxon Company, Limited, with its head office at 41 Rue de Berlin, Paris, and with selling branches in London, Berlin, Brussels, and Milan. A gold-plated Klaxon has been shipped from the Newark factory to the foreign representative to be given to the Queen of England. The business in the United States has assumed enormous proportions and is constantly increasing, both for automobiles and motor boats. Miller Reese Hutchinson is also the inventor of the Acousticon for the deaf, and a few years ago spent some weeks in London and restored the Queen's hearing to 90 per cent of its normal by his application.

English Firm Gets Timken Rights—The Timken Roller Bearing Company, of Canton, O., has made arrangements with the Electric & Ordnance Accessories Company of Birmingham, England, to manufacture roller bearings in that country for foreign trade. The Birmingham firm is controlled by Vickers' Sons & Maxim, Ltd., of London, one of the largest English commercial concerns. By this means the Timken products will be furnished to the automobile trade of Great Britain and the countries on the continent. There are few bearings of this type made in Europe, and it is expected that the American ones will meet a large field. The builders of the Wolseley cars have adopted them after exhaustive tests upon the roads.

Watch the Wheels—The experts of the Fisk Rubber Company have found that a great deal of tire trouble is occasioned by the fact that the wheels of the automobiles are not lined up properly. Frequently when the wheels strike curbs or other obstructions the axles or knuckles are slightly bent, and inasmuch as this is not particularly noticeable, the owners do not have the trouble remedied. Tires in such instances wear out with astonishing rapidity, and the Fisk men now make certain that the wheels are true before putting on the tires. When the tires are on wheels which toe in or out the stress falls to one side of the tread instead of on its center, and autoists are warned to look out for this.

Moline Factory Enlargement—Following the most successful season in its history, the Moline Automobile Company, East Moline, Ill., has just awarded a contract for the construction of another factory building. It will be 100 by 125 feet in size, with four stories, thereby increasing the floor space of the present plant by 50,000 square feet. Chassis and body assembling will occupy most of the extra room, and some will be utilized as a warehouse. The excellent showing made by the three Molines in the Glidden tour for the Hower trophy has created a widespread demand for Moline agencies, and the enlargement is the result of the increased business.

New Departure-Bristol Merger—According to President Rockwell of the New Departure Company, of Bristol, Conn., who is also president of the Bristol Engineering Company, these two companies will be merged as soon as the necessary formalities can be complied with. This action meets with the unanimous approval of the stockholders of both companies. It has been persistently rumored that the Bristol Engineering Company, which employs 200 men, was seeking another location because of lack of room, but the merger is expected to provide sufficient accommodations.

American Oil Company Doubles Capacity—At a recent meeting of the board of directors of the American Oil Company, of Jackson, Mich., it was agreed to double the capacity of the works, and to build a two-story brick office. These changes are to accommodate the growing trade in the American automobile oils, greases, and soap. An increase of 100 per cent was made during the year, and it is steadily becoming larger. The company now has branches in Chicago, Detroit, Saginaw, and Kalamazoo, and distributing agencies in Omaha and St. Louis.

Pierce and Thomas Teams in Base Ball Series—The question of base ball supremacy of the Pierce-Arrow and Thomas automobile plants in Buffalo has been a warm one during the season, and on Labor Day and the preceding Saturday the two came together. The Pierce-Arrowites won both games, the first by a score of 15 to 1 and the second with the tally 10 to 2. Now the Pierce men want to arrange a series with the Buffalo club of the Eastern League as soon as the latter's regular season is over, to determine the championship of the city.

Hokanson Agency Reorganizes—The Hokanson Automobile Company, of Madison, Wis., has reorganized under the same name, increasing its capital stock from $40,000 to $70,000. C. F. Spooner is now president, Emil Hokanson, vice-president, G. P. Miller, secretary, and Rudolph Hokanson treasurer and manager. The company plans to extend its system of branch garages and agencies through western and southern Wisconsin, and will also take up the manufacture of tops and other accessories.

Pope Mfg. Co.'s Additional Plant—The Pope Mfg. Co., of Hartford, Conn., has virtually acquired the plant formerly known as the Pope tube mills, situated just south of the Hartford Rubber Company's factory. During the old bicycle days this was one of the busiest factories in town, but it has now been for a long time unoccupied. The Capital avenue works of the Pope Mfg. Co. now employ nearly one thousand men, and it was deemed a matter of economy to acquire another building for the overflow.

Owen Thomas Stockholders Meet—The meeting of stockholders and directors of the Owen Thomas Motor Car Company, of Janesville, Wis., scheduled to be held in Chicago, September 7, to choose a location for the proposed plant of the company, has been postponed. However, it is believed certain that the plant will be in Janesville. Two Owen Thomas "Sixes" are already on the road.

Mitchell Works Three Shifts—A rush of orders for the 1910 models from all parts of the country has made it necessary for the Mitchell Motor Car Company, of Racine, Wis., to adopt the 24-hour day, and beginning this week three eight-hour shifts will be employed for at least three months. The company has already 900 men on its payroll.

IN AND ABOUT THE AGENCIES

Selden in Several Cities—Selden cars will be sold more widely during the coming season than ever before and agencies are being established in many important automobile centers. The Selden Car Company of Georgia will occupy a new and handsome garage building in Atlanta on November 1. It is located on Carnegie Way, opposite the Orpheum Theater and near the Piedmont Hotel. A five-year lease has been obtained. At San Antonio, Tex., the Selden will be represented by the A. E. Staacke Automobile Company. One of the most attractive stores now in Boston's automobile business has recently been opened by the Selden Motor Car Company of Massachusetts, at 801 Boylston street. The Selden Car Company of Pennsylvania was recently incorporated, and is located at 336-338 North Broad street. Louis Caswell, formerly sales manager of the Selden Motor Vehicle Company, is identified with the Quaker City business and expects to give it his personal attention.

Speedwell Agencies—The Speedwell Motor Car Company, of Dayton, O., has announced the following agencies for the coming year: Henry Dryfoos, Jr., Hazleton, Pa.; H. F. Van Cleave, 4209 Morgan street, St. Louis; Motor Car Sales Company (George W. Graham), San Antonio, Tex.; J. W. Goldsmith, Jr., & Company, 790 Peachtree street, Atlanta, Ga.; Budd M. Robinson, Joplin, Mo.; Hollis-Rand Company, Rochester, N. Y.; Thompson-Cuthbert Company, Portland, Ore.; Newbold Speedwell Company, Evening Star Bldg., Washington, D. C.

Pullman, Philadelphia—The Longstreth Motor Car Company, located at 1407 Race street, will handle the Pullman in the Quaker City and vicinity. The company will move shortly into new quarters, now in preparation, at 257 North Broad street.

Continental Tires, Nebraska—The Continental Caoutchouc Company, of New York, has delegated the agency for the state of Nebraska to the Western Automobile Supply Company, 1920 Farnum street, Omaha, Neb.

PERSONAL TRADE MENTION

Lewis H. Van Cleft, well known to automobilists as the steward of the Hotel Cadillac, New York, has recently opened his own café in the Gainsborough studio building at 222 West Fifty-ninth street. This is just off Columbus Circle and in the midst of the automobile district. On last Thursday evening Mr. Van Cleft entertained a number of the New York automobile writers and trade at a dinner to mark the opening of his season.

J. D. Cary, who has traveled for the past year in the South representing the B. F. Goodrich Company of Akron, has severed his connection with that concern to enter the employ of the Federal Rubber Company of Milwaukee, Wis. Mr. Cary will have full charge of this company's interests in the South among the automobile and carriage trade.

W. McKean White has become one of the chief aides to Alfred Reeves, general manager of the A. M. C. M. A., in the conduct of the Grand Central Palace show. Mr. White until recently was connected with THE AUTOMOBILE's editorial department, previous to which he was automobile editor of the Philadelphia *Times*.

Harry A. Mayer, of Baltimore, has joined the sales force of the Auto Supply Company, 208 West Saratoga street. He has been until recently with the James G. B. Davy & Company Supply House.

William L. Scribner, formerly of the E. R. Thomas Motor Company of Buffalo, has joined the engineering department of the R. L. Morgan Company, at Worcester, Mass.

OBITUARY

Charles E. Brown, vice-president and treasurer of the Shortsville Wheel Company, of Shortsville, N. Y., died on August 28.

FIRESTONE COMPANY ELECTION

AKRON, O., Sept. 13—At the regular meeting of the Firestone Tire & Rubber Company the following officers were elected: President and general manager, H. S. Firestone; vice-president, Will Christy; secretary, S. G. Carkhuff; treasurer, L. E. Sisler. The annual report showed an increase in sales of about 50 per cent. over the previous fiscal year, and in order to keep pace with the demands the concern is about to erect an immense plant.

HERCULES COMPANY ENLARGES

INDIANAPOLIS, Sept. 13—The Hercules Electric Company, of this city, has started its third factory enlargement since January 1, and is negotiating for the purchase of additional ground for further operations. This is caused principally by a new arrangement with Roger B. McMullen, of Chicago, by which he will hereafter handle the sale of the Kurtz high tension magnetos made by the local concern, in addition to his other automobile accessories. The size of his order was such as to require an immediate increase in the size of the plant, in order that deliveries may be made according to promises. With the prospective enlargements this will be assured. The Hercules Company cites this as another instance of the steadily increasing popularity of magneto ignition.

HARROUN BUMPER PATENT UPHELD

CHICAGO, Sept. 11—The Turner Brass Works of this city has had sustained the Harroun patent under which its bumpers are manufactured. Fifteen days after the filing of the suit against the Vanguard Mfg. Co. for alleged infringement, Judge Sanborn of the Circuit Court granted a preliminary injunction restraining that company from manufacturing, selling or using bumpers infringing on that patent during the pendency of the suit in question. The Turner Company has at present nine suits under way and means to fight each one. Any further infringements may result in other suits.

OLDFIELD HOLDS REMY BRASSARD

Barney Oldfield is now the possessor of the Remy brassard, the trophy offered the victor in the 25-mile free-for-all at Indianapolis. The fact that the handsomely wrought silver shield bears with it a cash reward of $75 each week makes it doubly precious to the great driver. The value of the trophy naturally produced a keen struggle. De Palma finished second in his Fiat, and Zengel was third in the Chadwick. Oldfield's time for the 25 miles was 21:21.7. The trophy will be raced for again at the September meet at the Speedway.

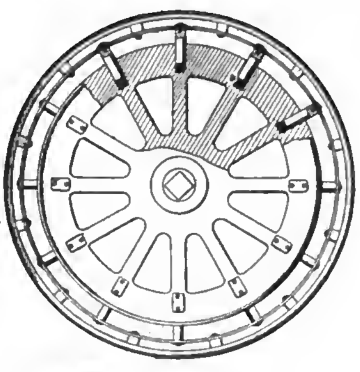
Remy Brassard Now Held by Oldfield

SOME SELECTED AUTOMOBILE PATENTS

Issue of August 17, 1909

931,048. Spring-Wheel—Ludwig Flum, Chicago. Filed June 26, 1908.

Interest in spring wheels and other methods of putting the tire manufacturers out of business, continues unchanged either in quantity of inventors and inventions or quality of the same. Flum's idea is to have a multiple felloe, three being shown in the patent office drawing. Of these, one seems to be very heavy and an integral part of the hubs to which it is connected by means of heavy, stiff spokes of short length. Beyond

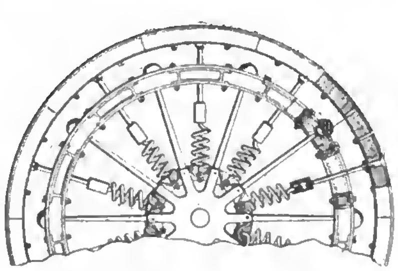


Flum's Spring Wheel Has Three Felloes

this, and attached to it by means of small diameter pistons, which are free to slide up and down, is the second felloe. This appears to be of very light spring steel construction, and carries on its outer side the true felloe to which the tire, or substitute for a tire, is fixed by short lugs. The construction seems to be, like many others of its kind, lacking in side strength.

931,214. Vehicle Wheel—Barrett C. Oblinger, Independence, Mo. Filed April 3, 1908.

Like Flum, Oblinger shows a partiality toward the multiple felloe, but uses only two. One, the inner, is firm and unyieldingly attached to the hubs by spokes of the usual variety, the ends of which project through the felloe and are capped with rubber buffers on the extension. This felloe is of a built-up construction, which is doubtless intended to yield some slight give or spring. The other or outer felloe is attached to a second series of spokes, one being placed between each two of the first-mentioned spokes. The secondary spokes have spring ends at the inner or hub ends, the attachment being a spiral spring connected to a spring steel plate. Like others, this would

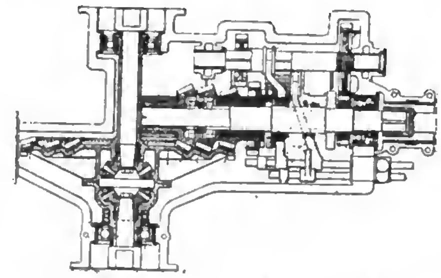


Oblinger Uses Spring Spokes Instead

have little lateral strength, while with the usual number of spokes, there would be little elasticity, since the rim is divided into half as many segments as there are spokes, resulting in each segment being large. It would therefore be either too stiff or too weak. It is difficult to see how freedom of movement could be combined with rigidity for driving.

931,288. Change Speed Gear—Powell Evans, Philadelphia. Filed March 6, 1907.

This is the well-known Evans transmission, which has been manufactured and marketed almost since the filing of the claim over two years ago. The principal feature of it is the number of direct drives which may be obtained as compared with others which yield but one direct drive on

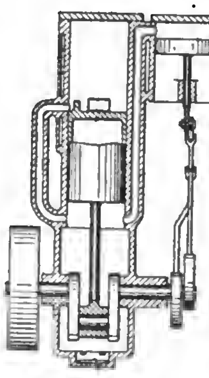


Change Gear Gives Direct on All Speeds

the high gear. With this form three differing drives are direct, this result being obtained by the use of three sets of bevel gears and pinions. All of these are driven from the engine and may be put into service at will by the use of the jawed clutch with which each is equipped. A single additional sliding gear gives all other speeds and the reverse.

931,346. Internal Combustion Engine—Erik A. Rundlof, Stocksund, Sweden. Filed Aug. 28, 1908.

Two cycle engines, like spring wheels, never fail to interest the inventors. This one differs only in that a separate chamber is provided for the compression of air or fuel as the case may be. This then passes into the crankcase, and thence through the transfer port into the cylinder. One point missed by the inventor is that the extra power absorbed by this separate compression chamber would wipe out all margin of present advantage over the four cycle, if any such actually exists.



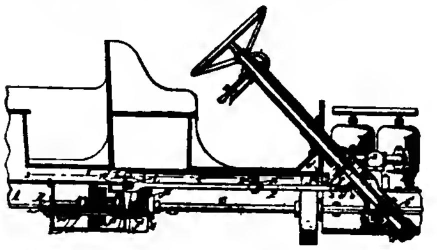
Rundlof Two-Cycle Engine

Issue of August 24, 1909.

931,770. Controlling Device for Change-Gears—Albert F. Krause, Buffalo, N. Y. Filed April 10, 1908.

The gear-change lever on the steering post so popular a number of years ago was abandoned primarily because it did not admit, with the construction in use at that time, the operation of a selective type of change-gear. In the opinion of designers, the selective change-gear had more weighty advantages than the steering-post control lever, and so the latter, other reasons aside, was dropped. At present it is almost entirely out of use.

Mr. Krause's invention is intended to reinstate this type of control in its former popularity by providing means for its use in connection with the now universal selective gears. The lever on the post has a movement in two planes, the usual swinging motion parallel to that of the steering wheel, and another up and down, which are imparted to a sleeve surrounding the steering column, the sleeve either revolving or sliding longitudinally. In the diagrammatic drawing shown, the sidewise motion of the



Device for Controlling Gears from Post

lever is used to select the desired sliding member, and the upward and downward motion to mesh its gears with those of the lay shaft.

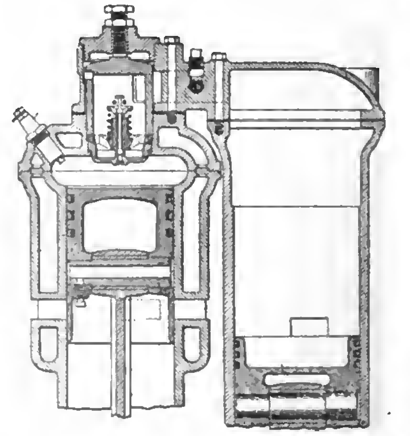
931,879. Automobile Tire—Charles E. La Fleur, Philadelphia, Pa. Filed Sept. 13, 1907.

This tire is of the usual construction in so far as it is built up of a woven carcase, a cushion of resilient rubber, a breaker strip of fabric and a rubber tread. However, the tread is made rather thicker than usual, and has a deep circumferential groove hollowed out of it, nearly reaching in to the breaker strip. A special tread is inserted in this groove, composed of fabric embedded in rubber, very tough and of small elasticity, in which the numerous layers of fabric are vertical when the tire is in position on the wheel, so that the ends of the fibers of the fabric may be brought to the surface to take the wear. The material of which this fabric is to be made is not specified; however, the tire should in any case be practically puncture-proof as long as the fabric layer remains of good thickness.

Vertical Fabric Prevents Punctures

931,837. Internal-Combustion Engine—Harry W. Beach, Montrose, Pa. Filed March 22, 1905.

This invention relates to a form of two-cycle motor in which the incoming charge enters through a valve in the cylinder head. The construction, as shown in the drawing, includes a separate pumping cylinder; al-

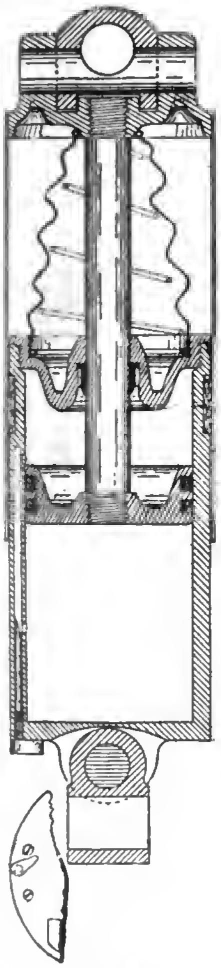


Beach Two-Cycle with Pumping Cylinder

though presumably crankcase compression could be used, this would involve a long passage up the length of the cylinder, which would be undesirable for many reasons.

Information for Auto Users

The Kilgore Shock Absorber—This device has been on the market and in practical use for the last five years and, like everything else in the automobile line, has been improved from year to year. It is now considered a standard article by the automobiling public. The Kilgore Mfg. Co., of 585 Boylston street, Boston, composed of prominent Boston capitalists, equipped a thoroughly up-to-date factory and commenced delivery of the improved shock absorber in January, 1909. Since that time it has been necessary to add to the factory and to run considerable overtime.



PLAN OF KILGORE SHOCK ABSORBER

The cut shows a cross section of the device. It consists primarily of a cylinder attached to the axle of the car and a piston attached to the frame. The principle is similar to that of the pneumatic door-check to prevent slamming. The cylinder is double-acting, so that either an upward or a downward movement of the piston compresses the air and acts to check the motion. A small air passage is drilled in the wall of the cylinder, allowing the air to pass slowly from one side of the piston to the other. If the piston makes a sudden jerk, however, this passage cannot accommodate the air fast enough to keep pace with the movement, and a damping influence is at once exerted. If the piston travels too far in either direction it covers up the opening in this passage, and the remaining air is compressed until the movement is totally checked.

The passage has a valve which may be adjusted to regulate the size of the opening as desired. Once set, this need not be changed. No resistance is offered to the normal action of the springs, but a sudden or violent movement is at once checked.

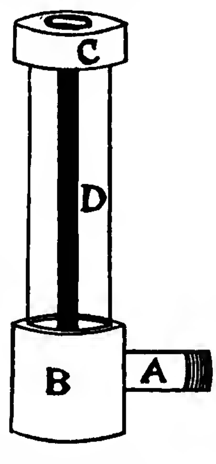
The shock absorber is constructed in the best manner throughout. The cylinder and piston are made of bronze, accurately bored and turned; the latter is fitted with two rings. The cylinder head screws in and has a packing gland to prevent air leakage around the piston rod. The upper end of the rod has a cap which carries a universal joint, connected in turn to the frame. From this cap a telescoping tube of seamless brass extends down over the cylinder to make the construction mud-proof. The lower end of the cylinder is made fast to the axle also through the medium of a universal joint, so that the device cannot be wrenched or strained by any movement of the car.

Firestone Demountable Rims—The new Firestone demountable rim is adaptable to any quick detachable tire, as well as to the regular clincher. Stay bolts are thus abolished and the security and time-saving features of the quick detachable rim are secured. This advantage can only be appreciated fully by the user of clincher demountable rims who has once attempted the extremely difficult operation of removing and refitting a regular clincher tire, with its short-stem stay-bolts, on the spare detached clincher rim. That weakness makes such rims a positive disadvantage, after the spare tire has once been used. There is also the possibility of more than one puncture occurring on the same trip. With the new type of rim, the user has one change immediately available through the spare tire, and, if necessary, can make additional changes with all the ease inherent in the detachable type of rim.

THE NEW FIRESTONE DEMOUNTABLE

The Firestone type of demountable rim is held in place by a ring of triangular cross section, in turn retained by eight bolts passing through the felloe of the wheel. The parts are so designed that they cannot stick from rust or accumulations of dirt. All angles of contact are so blunt that wedging of parts is impossible. There are no thin, narrow, wedge shapes, no complicated parts. No special tool is required. The entire operation is so simple and easy that there is no temptation to try it the wrong way. The demountable rims are adaptable to all quick detachable and clincher tires, and may be fitted without changing the present tire equipment in any way on practically any car, new or old.

"Apco" Crankcase Oil Gauge—The Auto Parts Company, of Providence, R. I., is making an oil gauge specially adapted to use on the crankcases of Ford models N, R, S and T. It is a small, simple device, readily applied with the assistance of a pair of pliers in ten minutes. Its use obviates the necessity of stooping down to try the oil with the cock; instead, the amount in the case is immediately indicated at a glance. The maker points out that oil costs money, and too much oil is not only wasteful, but also likely to cause sooted plugs and excessive carbon deposits in the cylinders, in addition to making the car a nuisance by giving out clouds of pungent blue smoke. The gauge is furnished with attachments for any Ford car. The company also makes a tool for redressing and cleaning the threads of tire valves, which looks as though it might give good service on occasions which frequently are all too familiar to the automobilist.



APCO OIL GAUGE FOR CRANKCASES

"Tray Plate" Storage Batteries—The Tray Plate Battery Co., of Binghamton, N. Y., has just moved into a new factory which will enable it to produce its "High Efficiency" batteries on a larger scale than heretofore. This company's batteries show a neat and workmanlike design, and their 6-volt, 60-ampere size used for automobile ignition is averaging 1200 to 1500 miles per discharge, according to the vibrator adjustment. These batteries have only recently been put on the market, after a three years' practical road test had eliminated every weak point which could be found.

The grid used is of the "checkered" type, which not only gives a greater capacity per square inch of plate surface, but also makes a plate of exceptional strength and durability, calculated to withstand the hard usage to which batteries in automobile service are constantly subjected. By a special process, the active material in the plates is made exceptionally hard and porous and the tendency to sulphate is materially diminished. Only rubber separators are used in the construction.

"HIGH EFFICIENCY" STORAGE BATTERY

The battery illustrated herewith weighs 27 pounds; its dimensions are 6 1-2 by 6 3-4 by 8 1-2 inches in height. This company also makes batteries especially designed for use in electric lighting systems, obviating the difficulties of gas generators and tanks. It has published a booklet on the relative cost of different ignition systems which, together with catalog No. 109, will be gladly mailed on application.

This company's line of batteries built for high rates of discharge are also worthy of attention among autoists who are contemplating the equipment of their cars with electric lighting systems.

INDEX TO ADVERTISERS

THE AUTOMOBILE

THE VITAL PROBLEM OF THE ROADS

35 M.P.H. Over Oiled New Jersey Road

50 M.P.H. Over Unoiled New Jersey Road

CLEVELAND, Sept. 21—In solving the vital problem of the roads the day has gone by when it was necessary to argue as to their value to a community. All are now agreed on this phase of the subject; the difficulty is to obtain the money with which to build. Then comes the really greater question of what kind of a road to construct to meet modern traffic conditions. Ex-Governor N. J. Bachelder of New Hampshire, Master of the National Grange, this morning, in one of the opening addresses of the Second Annual Good Roads convention, made direct reference to the startling change that has come in the movement for improving the surface of our highways.

This gathering of good road workers amalgamates the National Grange, U. S. Office of Public Roads, American Road Makers' Association, and the American Automobile Association, with the latter body through its Good Roads Board carrying the burden of the promotion of the affair, this time under the chairmanship of George P. Diehl of Buffalo. The manufacturers of automobiles are also aiding appreciably through the N. A. A. M., A. L. A. M., and A. M. C. M. A. The 1909 committee from the various organizations consist of: N. J. Bachelder, L. W. Page, J. H. MacDonald, L. R. Speare, Geo. C. Diehl, Robert P. Hooper, Charles T. Terry, W. F. Bonnell, S. D. Waldon, Coker F. Clarkson, Alfred Reeves, and F. H. Elliott.

In the assemblage which is attending the sessions in the Chamber of Commerce hall are grangers and autoists and road makers of national importance from all over the country, the former being the most plenteous in number. The Cleveland Automobile Club is doing the entertaining honors in no scant manner. The proceedings embrace in the Second Regiment Armory a comprehensive exhibit of road-making machinery and materials and sample bits of construction.

Roads are being talked about from early until late, and the discussions which follow the readings of the various papers of the experts are instructing and entertaining. The deliberations impress even the layman with the stupendous importance of the subject, and when Lieut.-Gov. F. W. Treadway this morning gave utterance to the statement that in his belief it was the greatest issue of the day his words elicited prolonged approval.

Even now before the convention has concluded its labors there is talk of next year's event, with three cities in action for the honor. St. Louis has Samuel Capen, president of its automobile club, as an exponent, backed by the mayor and local business organizations; Rochester, N. Y., is being energetically heard from through Bert Van Tuyle, who is secretary of the New York State Automobile Association; and Milwaukee has an effective shouter in James T. Drought, secretary of the Wisconsin State Automobile Association. Other candidates are known to be in the background and will be heard from before the dispersal Thursday night.

In the vicinity of Cleveland an unusually large number of contracts for road construction have been completed or are in process of completion at the present time. Nearly every type of road is provided for, which makes it possible for the convention delegates to gain an excellent idea of what might best suit their respective localities. This Committee on Practical Demonstrations contains well-known engineers from various states, cooperating with whom are the Cleveland city and Cuyahoga

50 M. P. H. Over Unoiled New Jersey Road in Recent Experiments

It was then that City Solicitor Newton D. Baker appeared on the scene and supplied a rhetorical welcome to the City of Cleveland.

G. A. Will of the Minnesota delegation arose and spoke of the most excellent good roads work of Governor Johnson, whose death was announced in the morning papers. Suitable resolutions were offered and unanimously adopted.

Chairman Diehl then took charge of the convention. Before introducing the following speaker the chairman referred to the enormous amount of work accomplished by the National Grange, whose aid was most essential in furthering highways' improvement.

State Highway Commissioner James C. Wonders of Ohio gave the history of the roads movement in Ohio, the first real work having been begun in 1907 by the State Highway Commission. Twenty counties and an expenditure of $240,000 represented the beginning, mostly in the eastern counties of the state. Gravel roads were the most numerous and satisfactory because of their reasonable cost, though brick paving at a heavier first cost proved the best surviving roadway. Moreover, the latter allowed more speed, which is not wholly distasteful to farmers.

county engineers. While this inspection is scheduled for Wednesday afternoon, not a few of those in attendance have covered more or less of the diversified route. Brick pavement is exceedingly popular in this state, and excellent samples of it are available for the inspection of the convention participants.

Tuesday Morning's Opening Session.

President L. R. Speare called the convention to order shortly after 10:30 o'clock. He read a message from Governor Harmon regretting the inability of the chief executive to give an official welcome from the State of Ohio. Likewise Mayor Tom L. L. Johnson was an absentee, ill health preventing his attendance. In the course of Mr. Speare's brief remarks, full credit was given to the press for the abundance of publicity given to the convention and good roads matters generally, with a further reference to the progressiveness of the Automobile Club of Springfield, Mass., which was the real originator of good roads gatherings wherein all classes of road users were invited to participate. The first National convention was that at Buffalo a year ago under the direction of Robert P. Hooper, then the Good Roads chairman of the A. A. A., the success of which was sufficient to insure a continuation of these meetings under the direction of the automobilists.

Lieut.-Gov. Treadway was next introduced, explained why he was a delinquent, and graciously told his hearers that they were welcome in the Commonwealth of Ohio. He referred to the roads question as the greatest issue of the day, and said when it was settled many other minor matters would be attended to at the same time.

Master of the Grange Bachelder said that a million grangers had preached the story of roads in and out of season and were entitled to a goodly amount of credit for the now unanimous chorus for good roads, which had become a National movement. The speaker asserted that other work was necessary besides the holding of conventions and meetings, which, nevertheless, gave excellent opportunity for a valuable interchange of ideas. No arguments were now necesary for roads, and the farmer believes that the National government is in duty bound to give aid. This was made evident by the report of the Country Life commission which corresponds with more than 500,000 farmers.

During the session a telegram was read from ex-President William H. Hotchkiss of A. A. A., which contained congratulations upon the assured success of the convention and expressed regrets that he was unable to be present.

New Jersey Road with Clay Road Bed Surface—Fairly Satisfactory

What Happened in the Afternoon

First of the talkers of the afternoon was State Highway Commissioner MacDonald of Connecticut, who can talk roads on a 24-hour stretch without a pause and all the time supply material that is meaty and interesting. Connecticut is one of the most energetic States in the matter of roads, and follows very closely in the wake of Massachusetts and New Jersey. Commissioner MacDonald naturally takes pride in the work that has been accomplished.

George S. Ladd, the special good roads lecturer of the National

Grange, had an entertaining subject in "The New England Plan for Connecting Lines of Trunk Highways." Mr. Ladd's success in his special field has been exceptionally notable.

"The Farmer's Interest in Road Improvement" was the subject handled in a masterly fashion by the Hon. T. C. Laylin, Master of the Ohio State Grange.

The Hon. F. N. Godfrey, Master of the New York State Grange, had for his subject "The New York State Grange and Good Roads Legislation in That State." Mr. Godfrey knows the science of road making, and how to get roads built, and the $50,000,000 appropriation in New York State has its existence in the effectiveness of the campaign waged by the State Grange.

George T. Barnsley, of the Automobile Club of Pittsburgh, read the paper of E. J. Kent on "Good Roads in the State of Pennsylvania," which are not as numerous as automobilists would like to see, the veto by Governor Stuart of the Philadelphia-Pittsburgh highway having been one of the disappointments of the last Pennsylvania legislative session.

Illustrating Roads Building in France—Showing Tree Protection

A general discussion, limiting each speaker to two minutes each, concluded the program for the day.

Brief Details of Second Day's Session

CLEVELAND, Sept. 22—The morning session of the Good Roads conference to-day was comparatively brief, but the three addresses given were among the most valuable of the convention.

Logan Waller Page, Director of the Office of Public Roads, had for his subject "The Road Situation in the United States as Compared with Foreign Countries," in the course of which he explained in a concise manner why many of our efforts have miscarried.

Chairman S. Percy Hooker, of the New York State Highway Commission, gave an excellent talk on "New York State Trunk Lines," and President H. H. Gross, of the Illinois Farmers' Good Roads League, spoke about "Illinois Good Roads," admitting that his State is just awakening. Then followed the road inspection trip to the various suburbs of Cleveland, with luncheon at Euclid Park Beach Hotel.

Much interest was aroused by the exhibition of road-making machinery and materials. This is free to the delegates, and nearly all of them took advantage of the opportunity to visit it.

EFFECT OF AUTOS ON ROADS TESTED IN NEW JERSEY

NEWARK, N. J., Sept. 18—Popularly current notions of the effect of automobile traffic on roads received a severe setback in the tests conducted by County Engineer Owen on Ridgewood avenue, Glen Ridge. The results obtained all go to show that automobiles, even at high speeds, do not have as destructive an influence on the road-bed as heavy horse-drawn wagons. Over a mile stretch of road eleven automobiles, weighing from 2,000 to 3,800 pounds, were driven at speeds of from ten to sixty miles an hour. At a low speed the automobile tires merely compressed and packed the road surface. The limit of speed at which no effect could be observed was about twenty or twenty-five miles an hour. At higher speeds a stripping action began, which if continued would cause loosening of the surface. However, the only dust raised was that already loose on the road.

After the automobile had finished speeding, five heavy coal wagons were drawn over the highway to ascertain the effect of this kind of traffic. According to the county engineer's notations the result showed that the hammering of the horses' calked shoes and the iron-tired wagon wheels tended to bring about a complete breaking up of the road. Large stones that were undisturbed by the autos were displaced by the horses and wagons.

"The wear and shattering of the surface of macadam roads," said Mr. Owen, "is not due alone to the automobile, but to the

Massachusetts Supplies State Highway Like This in Goodly Quantity

Road Across the Pocono Mountains in Pennsylvania

combination of this sort of traffic with horse-drawn vehicles. The roads of the future which are to take this travel and the methods of road maintenance of the future must be adapted to this end and with this point in view. The results of these tests were not in accordance with the general expectation or accepted opinions. Instead of the high speed breaking up the surface and scattering the loosened particles, no such results were noted. The dust that had accumulated was in all cases the only medium distributed." Mr. Owen's figures on the results of autos traveling at varying speeds were as follows:

For Telford Surface—Ten miles an hour, no trace left in center, compression of dust at side; twenty miles an hour, the surface dust spread sideways, but no stripping; thirty miles an hour, surface dust begins to strip; forty miles an hour, surface under tire swept bare; forty-five miles an hour, dust lifted, surface stripped, but no breaking; fifty-five miles an hour, road stripped bare, but no breaking; sixty miles an hour, road stripped bare, but no breaking.

Oiled Road—Thirty miles an hour, heavy oiled dust raised about one foot; forty miles an hour, heavy oiled dust raised about one foot; sixty miles an hour, strips dust. The high speed on the oiled road had no effect on the surface, either by loosening it or scattering the particles sideways.

Clay-packed Surface—Fifteen miles an hour, compression only; twenty miles an hour, dust raised; thirty-five miles an hour, heavy dust raised, no breaking; forty-four miles an hour, heavy dust raised, no breaking; fifty-two miles an hour, heavy dust raised, no breaking.

Where the tests were held the roadbed is about eight inches deep, of which the surface coating, originally three inches thick, was reduced to about two inches. The road has not been repaired for three or four years. No attempt had been made at dust-laying—in fact, the avenue was purposely neglected for the tests. The effect of the continuous automobile travel of recent years was to lay the center completely bare of the dust covering and loosen the smaller stone. Few large ones were displaced in a length of half a mile. The dust covering which accumulated on the sides was packed down fairly hard and smooth. In a stretch of half a mile only slight abrasion was apparent.

What One Finds in Crossing the Plains of Colorado

PROGRAM OF GOOD ROADS CONVENTION

TUESDAY, SEPTEMBER 21—MORNING SESSION

Opening Address—Lewis R. Speare, president of American Automobile Association.

Welcome to Ohio—Lieutenant-Governor Treadway.

Address of Welcome—Newton D. Baker, City Solicitor of Cleveland.

The Second Annual National Good Roads Convention and Introduction of Speakers—George C. Diehl, presiding officer and chairman of the national committee, directing the convention.

Good Roads of the State of Ohio—James C. Wonders, State Highway Commissioner of Ohio.

The National Grange and Good Roads—Ex-Gov. N. J. Bachelder, Master of the National Grange.

AFTERNOON SESSION

State Aid—James H. MacDonald, State Highway Commissioner of Connecticut.

The New England Plan for Connecting Lines of Trunk Highways—George S. Ladd, special Good Roads Lecturer of National Grange.

The Farmers' Interest in Road Improvement—Hon. T. C. Laylin, Master Ohio State Grange.

The New York State Grange and Good Roads Legislation in that State—Hon. F. N. Godfrey, Master New York State Grange.

Good Roads in the State of Pennsylvania—E. J. Kent, vice-president Automobile Club of Pittsburg.

WEDNESDAY, SEPTEMBER 22—MORNING SESSION

Convention Called to Order—By George C. Diehl, National Good Roads Chairman of A. A. A.

Road Situation in the United States as Compared with Foreign Countries—Logan Waller Page, Director of Office of Public Roads, Washington, D. C.

California Believes in the Petrolithic Proposition

New York State Trunk Lines—Hon. S. Percy Hooker, chairman New York State Highway Commission.

Illinois Good Roads—H. H. Gross, president Illinois Farmers' Good Roads League.

AFTERNOON SESSION

Practical demonstrations and road inspections.

Complimentary luncheon will be served at the Euclid Beach Park Hotel.

THURSDAY, SEPTEMBER 23—MORNING SESSION

Postal Progress League—James L. Cowles, secretary and treasurer.

Treatment of Earth Roads—D. Ward King, Missouri State Board of Agriculture.

Macadam Roads—A. B. Fletcher, secretary Massachusetts Highway Commission.

Bituminous Road Materials—Provost Hubbard, chemist United States Office of Public Roads.

Road Maps and Signs—Powell Evans, president Automobile Club of Philadelphia.

General discussion.

AFTERNOON SESSION

Boat ride on Lake Erie. Steamer "City of Detroit" will leave foot of Superior street. Complimentary luncheon will be served on board.

Theatrical performance, Chamber of Commerce Hall, at 8.30 P. M., by the famous Hermit Club of Cleveland. Music by Hermit Club orchestra.

Mud Roads That Abound Through the Middle West Are Best Traveled in Dry Weather

WHAT ONE MAN OBSERVED IN THE GOOD ROADS PROBLEM

BURLEY B. AYERS is the chairman of the good roads committee of the Chicago Automobile Club. Years ago he was one of the leading wheelmen in the country, and during L. A. W. days, he was prominent in its efforts to obtain good roads. Recently Mr. Ayers took automobile trips which included parts of Illinois, Michigan, Iowa, Indiana and Wisconsin, and in the journal of the Chicago Automobile Club he has some interesting comments to make. Extracts from his story are herewith given:

"The reason why such great states as Michigan and Illinois do not have good roads may be traced to the tenant-farmer system. In these States most farms are occupied by tenants, while the owners live in the little cities or villages. The farmers have to support two families. The owner expects the farm to yield all possible for the tenant and himself, and hence the least expenditure upon buildings, fences, roads and such improvements. The money is put into the farm machinery. This is evidenced by the general appearance of the farms. In the midst of great prosperity, with great crops growing everywhere, farmhouses and barns and roads and fences are dilapidated.

"In Wisconsin it is different. The Germans settled it and are there still, or their descendants. They still own and occupy the farms, and they have put their money into the houses and barns and fences and roads, and keep putting it in. No farming country in America shows such amazing results of prosperity as Wisconsin. Old barns and houses have been torn down and new and beautiful structures erected. No other farming country shows as many great barns with slate roofs, as many farmhouses with bay windows and big plate-glass fronts. No other State can display so many fine front lawns in front of the farmhouse, and generally makes such an exhibit of genuine country luxury as Wisconsin. All because the owners live on their farms, love them, and put in money for improvements.

"Talks with farmers all through these States absolutely show this to be the case, and also show evidence of a return to the old resident habit again. The trolley car and the telephone together form the cause. Many owner-farmers say they would not live on their farms under the conditions of ten years ago. Then they had to walk the plow, walk the harrow, walk the seeding, walk and hew and split and toil until the body was exhausted and life lost its joy compared with the life of the dullest crossroads village.

"But new farm machinery gives a new aspect to life on the farm. No longer has the farmer to hitch up and drive to the village for anything—the trolley takes him. The telephone summons aid and supplies that are sent out by the next trolley.

"Motoring through the great Michigan highway (deeply sanded) between Kalamazoo and Detroit reveals a strange absence of farmers' rigs. The farmers explain that where the road was once crowded with them, the way is now cleared for the automobiles to struggle with the sand, while they go to town by trolley. In Iowa and Wisconsin a great many use their motor cars. Iowa is much like Wisconsin in that the farmers own their farms, make them handsome, and contribute to their roads.

"And the deduction is this: There will be no good roads until the ratio of profit between the owner and tenant is so arranged that there will be a comfortable margin to draw on for the roads. While the fight is still on between owner and tenant for necessary improvements on the farm itself, the owning farmers will beat any bill in the legislature looking toward road improvements. And when one looks back on the history of these movements—notably the Michigan good-roads movement that recently came to defeat in the legislature—the cause is to be traced to just this source.

"Farmers are wonderfully interested in automobiles. Throughout the above-referred-to journeys, they readily yielded more than their share of the road. Iowa and Wisconsin lead in farmers' ownership of automobiles. They have many good points to offer about handling them, too, and the writer learned from Iowa that steel-studded treads were very efficacious."

PLANS FOR ROADMAKERS' CONVENTION

COLUMBUS, O., Sept. 20—The executive committee in charge of the annual convention of the National Roadmakers' Association, which will be held in this city October 26 to 29, has named the following chairmen of subcommittees: Invitations, Governor Harmon; reception and registration, Max Morehouse, president of the Columbus Automobile Club; entertainment, Herman Hoster; publicity, M. M. Maxwell, secretary of the Ohio Good Roads Federation; transportation, J. C. Wonders, state highway commissioner; programs, badges and printing, W. Hague; hotels and headquarters, H. C. Pirrung; speakers, George W. Lattimer; exhibits and demonstrations, Walter Braun.

FRANCE WILL HAVE A SINGLE-CYLINDER RELIABILITY

PARIS, Sept. 15—France has held many a pure speed contest for voiturettes, but has never dreamed of running a reliability and endurance contest for her little one-lungers. Following the example of the English club, which has made famous its reliability trials, next Winter there will be a reliability trial in France, the participants in which will be standard models of small two-seated voiturettes. The full regulations have not yet made their appearance, but it is understood that the vehicles provided for will be small single, twin, and four-cylinder cars not exceeding ten-horsepower and fitted with a two-seated body. It is the smallest type of car made in France and one of the most popular.

December 5 to 19 have been fixed as the dates, and the trials will be held in the neighborhood of Paris. For fifteen successive days the competing vehicles must daily travel 124 miles—or a total of about 1,860 miles—at an average speed of not less than 15 1-2 miles an hour. In the running time will be included the filling of gasoline and oil tanks, the oiling of the cars and any adjustments that may be necessary. As the start will have to be made from a garage in the suburbs of Paris, and a return made to the same point each evening, over roads that are always poor in Summer and decidedly bad in Winter, considerably more than 15 1-2 miles will have to be maintained at times in order to keep up the average.

The competing vehicles are two-seated voiturettes, of absolutely standard model, the maximum engine dimensions of which are 4 4-5 by 5 9-10 for a one-lunger; 3 9-10 by 5 1-10 for a twin-cylinder engine, and 3 1-10 by 4 7-10 for a four-cylinder motor. Stoppages allowed are for tire trouble, the cleaning of spark plugs, the tightening of nuts, the regulation of brakes or chains. Even the changing of a sparking plug will cause the loss of a clean score diploma.

No mechanic is allowed, but in addition to the driver each car must carry an official observer supplied by a rival firm, who will be charged to note all road incidents. The contest is the first of its kind held in France, and as small cars and voiturettes are now receiving a large amount of attention entries are expected to be high.

Although reliability trials have been inaugurated, voiturette racing has not come to an end. The organizers of the annual race for small one-lungers have just anounced that the sixth annual will take place next year as usual, the date being August 21. The regulations, which up to the present have been a limitation of bore, with unlimited stroke, have not yet been published.

PLEASANT COURSE FOR TRADESMEN'S TOUR

FOR varied and picturesque scenery and uniformly good roads, Long Island, the "Land of Pastime," can hardly be surpassed, and the second annual tour of the New York tradesmen, September 28, 29 and 30, will lead them through the heart of that pleasant country. Three days' touring, from one end of the island to the other, will make an agreeable break in the monotony of the season. From an early morning start at Columbus Circle, the caravan will leave Manhattan by way of the Queensboro bridge and take the Jericho Turnpike for Krug's Corner, long associated with memories of the Vanderbilt Cup races. Smithtown, 43 miles from New York City, will be the first checking station, and the participants should have no trouble in keeping to schedule time on this stage.

Thence the road leads straight to Riverhead. The route selected by the pathfinding party lies through a vast expanse of pine forest like that of the Lakewood region, where the air is sweet with the fragrance of the pines. At Riverhead the tourists will be regaled with a Long Island dinner. Here the route meets the course of the Long Island Derby and follows it to Mattituck. The night stop will be Orient Point, the extreme end of the North Shore. The fishermen of the party will go out in Plum Gut after bluefish, and dancing and games will close the day.

After an early morning start the cars will retrace their trail to Mattituck and will stop at the grandstand to witness the Long Island Derby, which is expected to provide some good racing. A tire and rim competition has also been arranged to demonstrate the practicability of the new types of demountable rims. After luncheon in the grandstand the tour will continue to Riverhead and will then cut across country to the South Shore by way of Flanders and Goodground. Passing through the picturesque Shinnecock Hills and skirting Shinnecock Bay the tourists will reach South Hampton and Amagansett, the extreme end of passable roads in the South Shore sand hills. The second night stop will be at The Irving, South Hampton.

The third day's run will lie along the South Shore, through Quogue, West Hampton, Brookhaven, Patchogue and Blue Point, famous for its oysters; thence through Islip and Bayshore to Long Beach, the noon control, where lunch will be served at the Hotel Nassau. When the tourists regain New York, by way of the Merrick Road and the South Hempstead Turnpike, they will have covered approximately 335 miles. The rules are liberal and should appeal to private owners, hut the schedule will have a tendency to keep excitement and interest from waning. At the same time it will be distinctly an event for the whole family.

FLORIDA'S NEW LAW SEEMS REASONABLE

TALLAHASSEE, FLA., Sept. 11—The legislature at its last meeting passed the new automobile law, which is meeting with general approbation. No fixed speed limit is named, but speed must always be "proper and reasonable, having due regard to the traffic and use of the highway." However, at crossings, sharp turns, and approaches to bridges the limit is four miles an hour. Automobiles must be registered with the Secretary of State, the fee being $2. Chauffeurs must also be registered. Non-residents registered in other states are exempt for thirty days. Automobilists are required to use reasonable care in passing horses and to stop on signal of uplifted hand. Imprisonment penalties are provided for second and third offenses.

MITCHELL MILITARY CAR ENDS TRIP

SAN FRANCISCO, Sept. 19—The Mitchell military car, carrying a message from General Wood of New York to General Weston of this city, arrived here at 2 o'clock this afternoon, after exactly a month on the road. Driver Zirbies, Lieutenant Rosenthal and Private Parrott, the crew, reported in good condition, although days of battling with rain and mud in Wyoming, following the scorching heat of Nebraska, had left their imprint on both faces and uniforms. At Evanston, Wyo., the tourists ran into a heavy snowstorm. From Salt Lake City to the Coast no especial difficulties were encountered. Considering the inexperience of the driver and crew in this sort of work, the time made for the long trip from coast to coast was very good.

U.S. Has Vice-President At New York State Fair Races

SYRACUSE, N. Y., Sept. 18—The greatest crowd ever assembled within the track enclosure of the New York State Fair grounds saw Barney Oldfield drive some fast miles and several other pilots go well under the mile-a-minute mark. Vice-President Sherman headed the list of distinguished visitors, and was greeted as a native son by the Uticans present. Twelve hundred automobiles filled the parking spaces, and the trackside was crowded with spectators. The race meet was arranged and conducted by the Syracuse Automobile Dealers' Association, the Automobile Club of Syracuse and the Syracuse Motorcycle Club. Although no records were broken, the times were fairly fast for a mile circular track, and there were some good contests.

Shortly before the third event, the five-mile free-for-all, an accident was narrowly averted which might have proved serious. Hanna, while tuning up his Hudson runabout, came down the stretch at a fast clip, followed by Oldfield and the big Benz, going at a much higher speed. Hanna slowed down opposite the upper end of the grandstand and carelessly swung across the track squarely in front of Oldfield. The latter, with great presence of mind, turned his car out just in the nick of time. Otherwise the little Hudson would have stood a good chance of being reduced to scrap iron.

The feature of the day was Oldfield's attempt to lower Ralph De Palma's mile circular track record of 50 4-5 seconds. Twice he dashed around the track, the first time in 53 3-5 and the second in 53 2-5, but that was the best he could accomplish. Then Barney took the wheel of C. A. Benjamin's Knox stock car for the ten and twenty-five-mile races, and made some fast time. In the former he had several brushes with C. H. Bowers in the resurrected Peerless racer, which finally burst a front tire on the ninth lap. Oldfield won in 10:57 3-5, followed by two of the Maxwells that participated in the Lowell meet. The twenty-five-mile race was to have been fifty miles, but was stopped at the halfway mark with Oldfield a mile in the lead.

The motorcycle races, as usual in meets of this kind, put up the closest finishes and were on the whole the best. A. S. Noonan finished second in both the five and ten-mile events, but was disqualified for failing to appear to have the cylinder of his machine measured to find whether it complied with the rules for stock machines. The summaries:

FIVE MILES, GASOLINE STOCK CARS, $1,250 AND UNDER

Pos.	Car Entrant	Driver	Time
1	Hudson—Amos-Pierce Auto Company	Hanna	5:49 1-2
2	Maxwell—Maxwell-Briscoe Company	See	
3	Maxwell—Maxwell-Briscoe Company	Costello	

FIVE-MILE, FREE-FOR-ALL—BEST TWO IN THREE HEATS

	First Heat:		
1	Benz—Barney Oldfield	Oldfield	5:15 1-2
2	Special—C. H. Bowers	Bowers	
	Second Heat:		
1	Benz—Barney Oldfield	Oldfield	5:06 3-4
2	Special—C. H. Bowers	Bowers	

FIVE MILES—GASOLINE—AMATEUR DRIVERS

1	Thomas—James Barclay	Barclay	5:55 1-5
2	Maxwell—Maxwell-Briscoe Company	See	
3	Maxwell—Maxwell-Briscoe Company	Costello	

TEN MILES, FOR GASOLINE STOCK CARS—OPEN

1	Knox—C. A. Benjamin, Inc.	Oldfield	10:57 3-5
2	Maxwell—Maxwell-Briscoe Company	See	
3	Maxwell—Maxwell-Briscoe Company	Costello	

TO LOWER MILE RECORD ON CIRCULAR TRACK

Benz—Barney Oldfield	Oldfield	0:53 3-5
Benz—Barney Oldfield	Oldfield	0:53 2-5

TWENTY-FIVE MILES, FOR GASOLINE STOCK CARS—OPEN

1	Knox—C. A. Benjamin, Inc.	Oldfield	25:40
2	Peerless—C. H. Bowers	Bowers	
3	Maxwell—Maxwell-Briscoe Company	See	

Barney Oldfield in Knox Winner

Hudson (Hanna) Winner 5-Mile

Maxwells Neck and Neck in 10-Mile

FIRST DAY OF MUNSEY TOUR SUCCESSFULLY COMPLETED

WASHINGTON, D. C., Sept. 21—Despite the early starting hour, all Washington seemed to be abroad this morning when the Munsey reliability contest was sent away from the Munsey building. So dense was the crowd, that it reminded one forcibly of the Glidden start—minus the cannon. It was the original intention to send the first car away at 7 a. m. sharp, but an accident to the elevator at the official garage not only put one of the contesting cars—Matheson, No. 27—temporarily *hors du combat,* with a smashed fuel tank, but marooned five of the cars on the second floor. Quick work by a corps of helpers got the quintet down to the street level in short order, and an extra fuel tank was secured to take the place of the one the Matheson lost when the lift dropped. Referee Trego allowed the crew of the disabled car to check out as soon as repairs were completed, at 9:33.

The Trophy That Is Contested For

Besides the contesting and official cars, there are two non-contestants—an Autocar truck with P. J. Thacher at the wheel, and a Detroit electric driven by George M. Bacon. The truck is carrying extra confetti and passengers' baggage.

There is one lady on the run—Mrs. Frank P. Hall, wife of the owner and entrant of the Columbia, No. 15. This plucky enthusiast vows she will cover the entire 1,282 miles.

For various reasons, but 25 of the original 37 entries put in an appearance at the start this morning. It was rumored that a few of the delinquents demurred at the stringent rules, but it is probable that this was not the true reason for their failure to have their cars in Washington in time to undergo the preliminary examination by the technical committee. Accidents kept out at least two prospective entrants. The Acme was one of these. One entrant gave as a reason for his delinquency that he was "too busy." Others had sold the cars they had intended to enter. Still others advanced failure to secure 1910 models as their reason. These recalcitrants destroyed the hopes of the Munseyites that their run would out-Glidden the Glidden in importance—at least so far as the number of contesting cars was concerned.

Yesterday and Sunday technical committee chairman Frank H. Trego and his assistants, "Doc" Overpeck and Jesse L. Cassard, worked overtime at Warner's garage, examining and sealing the 25 cars. By working rapidly they were enabled to finish their task before sundown. Six of the contesting cars have been entered by private owners—Frank P. Hall's Columbia, George F. Whiting's Winton, H. Clay Waldman's Pullman, John J. Loughran's Reo, T. S. Patterson's Selden, and Frank Hardart's Elmore. The remaining 19 represent sixteen of the best-known American makers, the several factories having sent on their crack drivers to capture the honors in what is in every respect the most important endurance event held in the East this year.

The official cars number seven, as follows: Chairman, National, John Aiken, driver; Press No. 1, Stüdehaker-Garford, Robert Yerger, driver; Press No. 2, Chalmers-Detroit, Joe Matson, driver; Press No. 3, Premier, W. Leslie Walker, driver (private car); Pilot, E-M-F, William Stark, driver; Pilot, Midland, D. C. Johnson, driver; Starter, Maxwell, Harry Walls, driver.

Shining lights among the drivers are not wanting. Billy Knipper, fresh from his Lowell victory, is out for the fourth division honors in his Chalmers-Detroit; Joe Matson, the Indiana trophy winner, is at the wheel of another Chalmers-Detroit which is carrying a bunch of pressmen; John Aiken is handling the big National Six in which Chairman Trego and several Munsey writers are traveling; Bob Yerger, one of the crew of the Studebaker which landed the Philadelphia-Savannah mud-plug a couple of years ago, also has a bunch of Fourth Estate men in his Studebaker-Garford; Walter Wood, American Simplex; Billy Soules, Croxton-Keeton; Leo Shaab, Renault, and Frank Hardart, Jr., Elmore, are others who have made records on road and track, and who are out for the honors in their respective classes.

The contest is being run under class A of the A. A. A. rules for 1909, and the cars are divided as follows:

DIVISION 1 ($850 and under)—Ford, 7; Hupmobile, 29.
DIVISION 2 ($851 to $1,250)—Maxwell, 9; Reo., 26.
DIVISION 3 ($1,251 to $2,000)—Washington, 5; Pullman, 12; Crawford, 24; Washington, 31; Washington, 32; Pullman, 37.
DIVISION 4 ($2,001 to $3,000)—Chalmers-Detroit, 1; Maryland, 11; Spoerer, 14; Columbia, 15; Croxton-Keeton, 17; Corbin, 18; Winton Six, 20; Marmon, 30; Selden, 34; Elmore, 36.
DIVISION 5 ($3,001 to $4,000)—Pullman, 13; Croxton-Keeton, 16; American Simplex, 21.
DIVISION 6 ($4,001 and over)—Matheson, 27; Renault, 28.

The cars were sent away this morning in the order named, with the exception of the disabled Matheson, and this procedure will obtain throughout the entire run. To-day's running time being over nine hours (195.3 miles), the first division cars were given 100 minutes' leeway over the big fellows in the sixth division. The second division pair were accorded 80 minutes excess time; third division, 60 minutes; fourth division, 40 minutes, and fifth division, 20 minutes.

How the Cars Arrived at the Quaker City

PHILADELPHIA, Sept. 21—Of the 25 cars which started this morning on the first leg of the Munsey reliability contest, all reported, and it is believed that but one time penalty will be inflicated—a better indication of the quality of the roads covered than paragraphs of description. The one exception was a 3-point penalty on the Winton Six, due to a balky motor. With the exception of a few stretches between the capital and Baltimore and the miserable cobble-paved streets of the latter city, the going, for the distance, would be rated as excellent. Little difficulty was experienced, even by the small fellows, in maintaining their schedule; in the majority of instances they could have finished clean as regards time, even without their handicaps. Penalties for work on the road, however, were so plentiful that the committee at midnight was still wrestling with the figures.

Despite the excellent going, tire troubles were numerous; but as the rules give the contestants credit for time spent in tire repairs, no damage resulted.

Only one foreign car is in the run, Leo Shaab's Renault, which was among the first at every control, and finished right after the pacemaker at to-night's control.

The Detroit electric, one of the non-contesting cars, left Washington several hours before the contestants, and, making a very fast run, was the first car to reach Baltimore. The distance between the two cities was covered in one hour and fifty-six minutes.

Quaker City, Philadelphia and Century clubs are having "open house" to-night, and the visitors are having the time of their lives. The Quakers have put on a smoker and vaudeville show at the Hotel Walton, the official headquarters.

TABLE OF FIRST DAY'S PENALTIES

First Division—(7) Ford, 1.7; (2) Hupmobile, 2.0.
Second Division—(9) Maxwell, 0.26.
Third Division—(5) Washington, 2.0; (31) Washington, 1.0.
Fourth Division—(1) Chalmers-Detroit, 2.0; (14) Spoerer, 3.0; (15) Columbia, 1.0; (16) Croxton-Keeton, 5.0; (20) Winton, 1.1; (34) Selden, 2.0.
Sixth Division—(27) Matheson, 4.0.

Note—All other cars went perfect, except for the single time penalty imposed on (20) Winton, 3.0 points for late start.

Automobile Wheels, Rims and Tires

By Thos. J. Fay

In a discussion of the action of road shocks upon an automobile wheel, it is possible to draw a very close analogy to the action of a hammer striking a series of blows upon an anvil, and the reaction of the same. To carry out the comparison, glance at Fig. 26, which represents an anvil and a series of hammer blows upon the same. This might be any kind of an anvil and, similarly any sort of a hammer. In each and every case, the distance, which the hammer will rebound, after the anvil is struck, depends upon the part of the anvil struck. As the figure shows, if the anvil is struck fairly at the center the hammer will rebound the greatest distance, because the blow will be against the greatest section of the anvil and the motion will be arrested quicker. It is not the weight of the hammer that counts so much as it is the time (or distance) in which the motion is arrested. Out on the horn, for illustration, where the anvil is far less rigid, the rebound of the hammer is reduced very much, and transferring this same idea to a wheel renders it obvious that short spokes will act just as the center of the anvil, and very long spokes will perform just the same as the horn of the same. The energy of impact then may be much or little, merely depending upon the diameter of the wheels, just as it is in the case of the anvil, depending upon the point of contact of the hammer, in view of the rigidity of the section of the anvil.

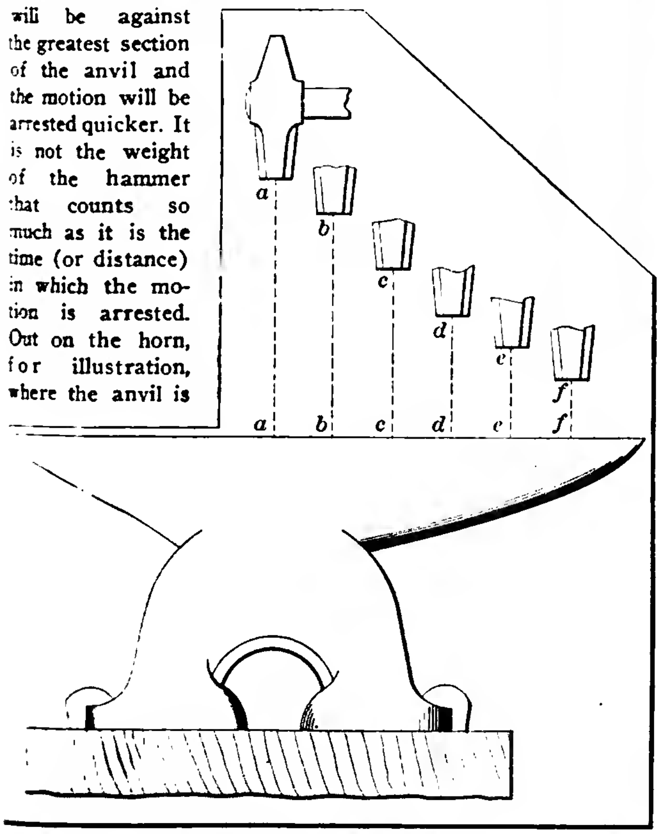


Fig. 26—Anvil and hammer blows, showing principle of arrested motion and impact

It is on this account that high wheel automobiles are enabled to make good speed on roads of no great pretense, although pneumatic tires are not taken advantage of, and even the solid tires used are of small sectional area, because it has been found that the spokes of the wheels, they being of considerable length, and limiting the rubber serve the treble purpose of lowering the cost, reducing weight and eliminating bouncing effects.

The modern tendency in pneumatic tire work is in this same direction, and it is self-evident that long spokes, if they hold resilient qualities, have the further advantage of low cost and long life.

Importance of Service Tests—These must be relied upon to tell the real story in the long run, excepting that certain selections of wood for illustration, foreshadow success, or failure, from the start. Fig. 27, which is reproduced from a photograph taken at the plant of the Pierce-Arrow Motor Car Company, at Buffalo, presents all the elements of success or failure, side by side. The billet of wood, at the left, as accepted by the makers, is sawed from second growth hickory of the variety as found native to Missouri, after the trees are felled green, cut into lengths, corded, weather seasoned, and then cut into billets, from which spoke stock is carefully selected and the ends painted to prevent checking.

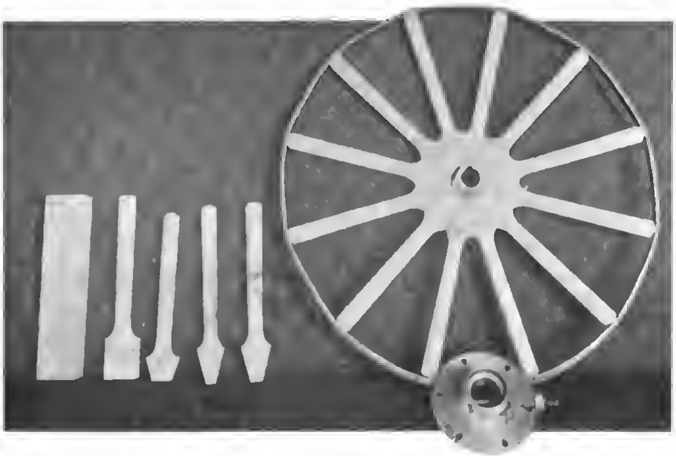

Fig. 27—Showing from left to right, billet, blocked out spoke, finished spoke, scrap, and one with a rusty streak, besides a set ready for the felloe

A roughed spoke along side of the billet, in the same figure, indicates the second operation, and when the spoke is thus blocked out, it is possible to ascertain if it will be good enough

Fig. 28—Reproduction of wood from a broken wheel, showing heart wood, slightly discolored, regular grain, and evidences of strength

Fig. 29—Depicting part of a broken wheel with more uniform grain and no discoloration whatever

Fig. 30 — A dead wood spoke which failed in service

for wheel work of the first class. If knots uncover, or if the grain crops out, even though the wood may be close, of good color, and free from blemishes in the main, it will be necessary to condemn the spoke. The next operation is to miter the spoke, which is done on a machine, so that accuracy is a matter of setting the same to give the required facing angles. The third from the right in the figure shows just such a spoke sufficiently perfect as respects quality of the wood to be used in a Pierce car, but the fourth spoke proved to be of the "bastard" variety, so-called, since the grain cropped out part way up from the miter end. The fifth spoke shown is free from all but a color imperfection. This streak might not do harm, but the wood looked somewhat soft and punky and since spokes are subjected to torsion under some conditions, this imperfection might result in a split spoke in service.

The set-up woodwork shown to the right represents a set of spokes of a wheel just after they were drawn up, and the miter joints are so close that the seams are scarcely noticeable. The glue used is of the finest grades obtainable, and by repeated tests it has been found that joints so made, if the miter angle is correct, are stronger than the cleavage section of the wood. This condition is fortunate since it permits of handling the built-up woodwork in the after operations, and allows of retaining all the bearing surface of the spokes, on the ends, against the barrel of the hub, in service.

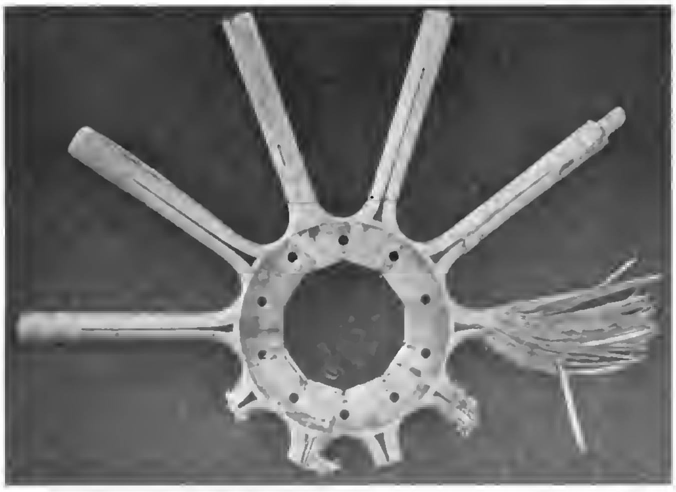

Fig. 31—Indicating the strength at the miter obtained by use of well-matched joints and plenty of good glue

What an Actual Service Test Indicates—The broken wheel, Fig. 28, shows a discolored condition of the wood, and while discoloring may not of necessity portray a condition of lowered strength, even so, the chances of attaining the best results are reduced. True, all the spokes illustrated (excepting Fig. 30) were in wheels that were in collisions or other violent wrecks, and they would not be expected to survive no matter of what material they may have been made. Fig. 29 represents just a little advance, since the wood is a little more uniform in all respects and quite free from discoloration.

Fig. 30 represents a spoke which cannot be regarded as of any value in automobile wheel making, and the Pierce wheelwright, Mr. Johnson, took it as a souvenir from a wheel that failed on small provocation, and in discussing the matter, very aptly brought out the fact that when wheels are painted it is extremely difficult to ascertain just what kind of wood may have been used. The spoke is of greater section than that customary in Pierce, and other cars of quality, and is a good illustration of the futility of size if the material is defective.

Fig. 31 depicts a wrecked wheel, which came from a car that was struck by a locomotive, and it shows to a nicety how well the glued joints will hold when they are well made. In Fig. 32 there is a chance to notice a certain amount of variation of wood even when selections are made by men of skill, although, in this example, it must be admitted that the wheel probably would have outlasted the rest of the car had it not been in a violent collision. Fig. 33 also, of a wheel that went through usage which wrecked the whole car, is a normal example of the grades of wood used in the Pierce plant, and this example affords an excellent opportunity to ascertain just how second growth hickory performs.

Fig. 32—Evidence of the changing strength of wood in the several spokes even with the very best of selection

Fig. 33—Illustrating a wheel of great strength with uniform wood as selected by the Pierce wheelwright

Modern Methods of Building Wheels—When the felloes are put on, the wheels have to be trued up and it is of the greatest importance that this operation be performed with the same precision as that attending the truing up of a flywheel. The machine used for the purpose has all the elements of accuracy and by its use the work is done expeditiously, while the personal equation is eliminated.

With the wheel trued up, after the felloes are in place, the wood work is then ready for the rim, and in the setting of the same there is ample opportunity to ruin the wheel. In the old way, the rims are put in a fire and heated up to almost a dull red heat to expand them sufficiently to slip over the felloe with ease, and when they are cooled off, by sprinkling water over the wheel, the dry wood, just as it comes from the kiln, is in a condition to lap up water at a rapid rate. The water, so absorbed, will swell the wood, and when the wheels are painted the water will be locked in, there to remain for some time, probably until the wheels are allowed to stand out in the heat of the sun for a few hours. After this the wood will distort, the miter may open up, and on the whole it is scarcely possible to make a wheel of the first class if water is allowed to contact with it after the wood is kiln-dried and before a protecting coat of paint is applied. It must be understood that it is the proper function of the paint to keep water out and not to lock it in.

In the Pierce plant, in order to avoid such difficulties and to realize a more uniform pressure when the rim is applied, a hydraulic press, as shown in Fig. 35, is used in the manner as follows:

The rim is heated to a temperature which will scorch paper when it is in contact, and in this heated state it is set into place with the wood wheel, on the platen of the press. The diameter of the rim is slightly less than the diameter over the felloe, so that, even when the rim is heated, it will have to be pressed over the felloe. The work is so carefully done that the pressure is nearly the same with all wheels, and in a number of cases which the author noted the pressure ran up from 25 to 60 tons.

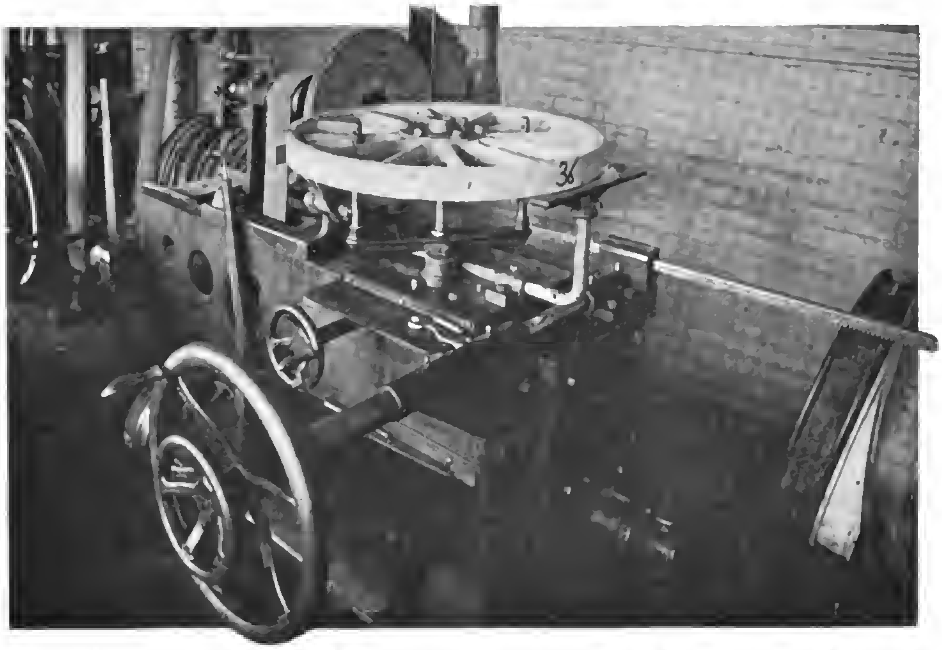

Fig. 34—How the woodwork is trued up in the Pierce-Arrow wheel department, a rapidly rotating emery wheel being used to do the work

When the rim cools, which it is allowed to do in the open air without the use of water, it contracts, and, as a result, besides the pressure of about 25 tons, there is the pressure due to contracting, so that the wheel is bound together very firmly.

In these days when demountable tires are used to a great extent, the stationary rim must be put on with more than a little care, the sectional area of the same must be adequate for the work, and that a press, as illustrated, represents the surest way, seems to be proven by the results attained.

(To be continued.)

SPRINGS OFTEN CAUSE NOISE AND TROUBLE

Springs should be examined occasionally, and while often overlooked, this seemingly trifling matter has a direct bearing upon the smooth, easy running of the car. Owing to the fact that the springs are exposed to the weather, rust is very likely to occur at this point and to this unsuspected corrosion is often due the occasional "squeak," which my garage experience tells me is not always followed up by the driver. Although many cars are provided with some means for lubricating the friction surfaces, many cars are not so well provided for and when rust makes its appearance along the joints there is a crying need for oil. This may be conveniently applied by placing the jack between spring and frame, and slightly opening the leaves or plates. The toggles and links should also have a little oil occasionally and when about this work it is well to examine the nuts of the clips. These nuts are prone to work loose.

The steering gear should always be given proper care and the levers, pins and joints should be kept free of dirt and well oiled. This is a very important matter and as neglect may result in a bad accident, injurious to both driver and car, this important mechanism should be given frequent and critical examination.

FRACTIONAL DISTILLATION IN TESTING FUEL

Specific gravity tells nothing worth knowing about automobile gasoline since the same is made up of a plurality of fractions of the distilling process by which the components of mineral oil are separated out. Specific gravity, if it is known, provided only one fraction is measured, will tell if the same is above, below, or a given standard. As it is, considering the real composition of gasoline (so called), the first thing to do is to separate the fractions from each other, and in the process ascertain the percentage of each in the whole. Having in hand the information of this character, it will then be possible to test each fraction, to ascertain as to its fuel value. The hydrometer will come in handy in the process of determining the density of the respective fractions in the distilling process. The distilling process is attended by much danger, owing to the explosive nature of the hydrocarbon liquids; care should be exercised, and the process should be conducted in conjunction with the use of good facilities for the purpose.

Fig. 35—Hydraulic press which forces the rims on to the woodwork after the rim has been expanded by heating to about 600 degrees C. A pressure of 25 tons may be exerted

ADVANTAGES OF SAND BLAST IN AUTOMOBILE PRODUCTION

REACHING after quality is a process which either increases cost or demands refinement, be it in the automobile or any other line of work. In a visit to the plant of the Pierce-Arrow, among the many methods employed, the process of sand-blasting stands out with more than ordinary prominence, due to the wide range of its application.

When this process of cleaning castings was first introduced it was looked upon as of value for the purpose of removing core-sand, scale, etc. It was a strictly foundry proposition then, and few were the shop managers who saw in it a method of locating defects in drop forgings and other parts of steel.

The process is simple, consisting of a source of compressed air, quantities of clean, sharp sand, a properly devised hopper and a hose fitted with a nozzle, as illustrated here. With this equipment, the workman is enabled to reach every part of a casting and clean it out. This is of the greatest importance in connection with cylinder castings, on account of the intricate cores and cramped spaces, some of which are quite inaccessible to tools of the conventional sort.

Workman In Garb and Mask Sanding Drop Forgings to Remove the Scale

The extension of the sand-blast to other work, however, enables the workmen to clean the forgings, eliminate scale, and expose all defects such as can be discerned, once the scale is removed and the virgin metal is open to view. A weld in an axle, for illustration, which might go unnoticed otherwise, will show up with great certainty after the sand-blast has done its work. In the Pierce-Arrow plant at Buffalo all drop forgings and in fine, every piece that goes into the car, is subjected to this process, with attending advantages, which may be summed up as follows:

(A) Core-sand is properly removed so that the water system will not be clogged up.

(B) Forgings are partly cleaned of scale and tools last longer.

(C) Poor welds are discovered and deception is coped with.

(D) Parts present a more even surface and take finish better, moreover the finish stays on more tenaciously.

How the Workman Is Protected from the Cutting Sand—As the figure shows, the workman must be protected when he is doing this class of work, and besides endeavoring to keep sand out of his internals, he wears mittens and a mask in order to prevent the flying sand from cutting through the skin.

Of a necessity, the work is conducted in a room, or rather department, somewhat isolated from the rest of the works. The flying sand with its natural hardness and propelled as it is by the high pressure of the air behind it would make short work of even the toughest skin. For this reason the sand blast at the Pierce-Arrow plant occupies the first part or front end of the so-called brazing building, a one-story structure 377 by 55 feet. Of this, a nearly square room is utilized. This is divided into two parts, one containing the large diameter fan and the sand bin or storage. Within the other half are placed the blast rooms proper, and a broad hall for material storage.

These rooms are three in number, about twelve feet square. In the center of each one is a sort of table upon which the work to be cleaned—for this is primarily a cleaning operation—is laid. The tables, of which the picture shows but a corner, are made up of a simple gas pipe framework, upon which are laid long narrow strips of wood resembling laths, but about eight feet long.

Over this, and having an equal size, is placed a hood which resembles the hood placed over a blacksmith's fire. Furthermore, the resemblance may be carried further, for the blacksmith hood is to remove the deadly fumes from the coal, while the hood in this case is to remove the floating particles of sand, which are equally dangerous to the throat and lungs of the operators. This upward draft is not relied upon solely, for the men wear, as the picture shows, a headgear, with glass covered openings for the eyes.

The compressed air is stored in a large tank in the corner of the passageway, this being both of large size and large capacity. A pressure of about 200 pounds per square inch is maintained therein at all times. In each of the three rooms a smaller tank holds air for immediate use, at a lower pressure of perhaps 125 pounds per square inch.

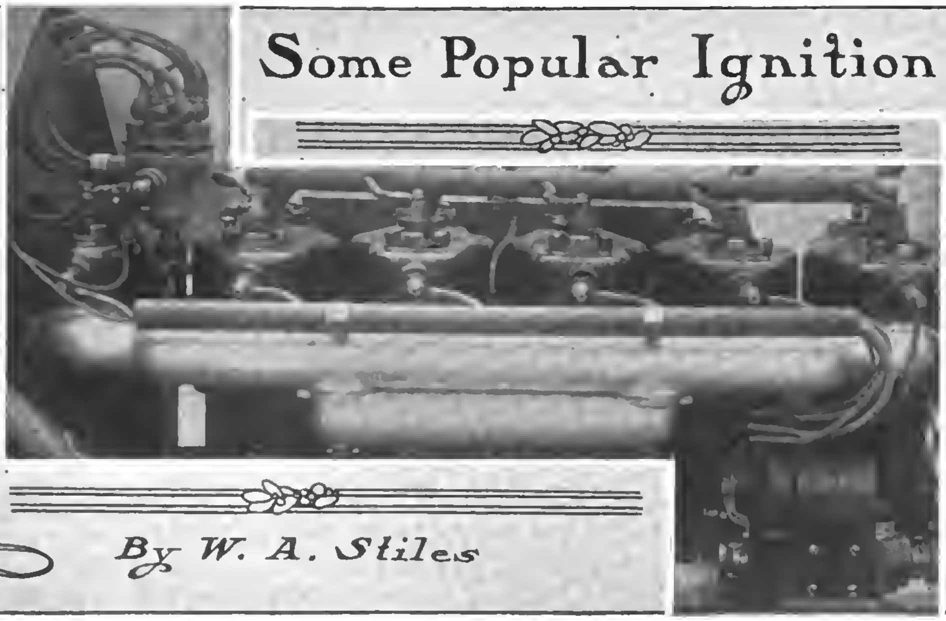
Nozzle Construction and Method of Operation—At the nozzle, there are two pipes leading in and but one leading out, the latter the nozzle proper. Of the two former, the smaller one conducts the air, which in its passage sucks the sand through the other of much larger diameter. A shut-off cock regulates the flow of air, there being no necessity for regulation of the sand, as that stops flowing as soon as the air is shut off. To go to work on a piece, it is laid on the table or bench, the workman dons his mittens and hood, brings the nozzle over to the table, turns on the air, and with the first rush of air under the high pressure, the sand is also sucked out and the work has begun. When the whole surface of a piece has been gone over to the operator's satisfaction, the air is turned off, the nozzle laid aside, and the piece removed to make room for others. Very small pieces are not laid on the table, but are held in the hand, while the blasting process is going on.

In the beginning, the blast was used, as stated previously, for cleaning castings, but by trial it was found to give to the surface of forgings a superior surface, both as to appearance, which is worth a good deal now-a-days, and as to smoothness. The latter was desirable in the paint shop, for it eliminated many hours of laborious hand work cleaning rough forgings, while the time it actually consumed was so small as to be negligible.

Thus, the paint shop savings were noticeable, so much so that this method was applied to many, if not all, of the unfinished parts which were to receive a coat of paint later. With this came the discovery that not only was the life of the painting coat lengthened on rather rough surfaces, but that smooth ones as well were benefited by its application. So, many finished parts, as, for instance, the aluminum fenders, were sent to the sand blast to receive a "roughening" treatment. The utility of the method was then not alone smoothing the surface of very rough parts, but slightly roughening the surface of highly finished ones.

Today, so much progress has the process made in these minor economies, that no American plant of prominence is without a sand blast. With the increasing number of dull finishes used this process assumes a more important place in the industry.

Some Popular Ignition Fallacies Made Clear



By W. A. Stiles

SOMETIMES amusing, and often exasperating are the experiences of the trouble man who is sent out from the factory at more or less frequent intervals and runs up against the car owner, who knows just where the trouble is, and who would have fixed it himself had he not thought it better to call in an expert. To appreciate fully the advice which is generally given him from the start of the job to its close, the trouble man should select the type of car which has its timer shaft lying horizontally along the engine base, disappearing modestly into the dark regions somewhere under the footboard. The timer is usually worn out, and must be taken off, so he will probably assume a stooping position across the frame, with head and shoulders somewhere in the vicinity of the clutch, and as he begins to skin his knuckles in getting the confounded thing off, he will listen to a rapid-fire monologue somewhat after this style:

"And after we got about fourteen miles out into the country the blankety-blank thing laid down. Yes, sir, it just quit. So I took a fine file and cut notches on each side of the vibrators to make them weaker, and when I got them back in place off she went like a top. You fellows make those tremblers too stiff altogether." (The factory man takes good care to replace those chopped-up vibrators before he leaves.) "And then you ought to have a larger whatd'yer call it on the contacts. These don't last any time; some only a couple of weeks." (He dresses them down twice a week with a file.) "It's a bum outfit anyhow; my engine gets hot now, and it didn't on my old car when I had the ——— system; the steering gear is loose and the front wheels wabble"—and so on ad infinitum.

A Single Spark Will Do the Work—These delusions, however, may be set down as individual "grouches," and the same ones are seldom encountered twice. There are, though, certain fallacies which have gained ground in the public mind, and it is of these that I shall speak. The first is an idea which is being dispelled today under accurate tests, and is no longer seriously considered by scientific and mechanical men in the automobile business; namely, that a series of sparks are better than one, because a shower of sparks ignites the gas better than a single one could do, and more quickly. When it is considered, however, that an eighth or more of the explosion stroke will occur between the first and second sparks, even with a moderately rapid vibrator, it becomes evident that the second spark, as well as all subsequent ones, take place in either a flame or a hot but dead gas. The most careful dynamometer test will show absolutely no gain of power through the use of four, six or even ten sparks for each explosion. Indeed, it would seem to be a fact that the positive synchronism of the mechanical single-spark contact maker is productive of better results, speaking in terms of horsepower, than the multiple-spark system.

The next is a point which I shall touch upon very carefully, as it is an idea based on more or less (mostly less) truth, and has many adherents among motor manufacturers today. It concerns the relation of horsepower with spark heat. There is no question but what a small white thread spark, such as might be given by a broken-down coil, will give less satisfactory results than a good, rich spark, normally full in body heat, but the most careful and impartial tests have failed to show any variation of engine power, whether a good coil was used or a high-tension magneto. Laying aside the many arguments pro and con this subject, for practical purposes it is a fact that the gas mixture either explodes or does not explode, and if the latter, the explosion will be of the same heat and pressure regardless of what set it afire. It should not be inferred from this that the mixture can not be made to explode slowly or quickly, as it is a well demonstrated fact that two sparks fired simultaneously into opposite sides of the cylinder will assist materially in rapid combustion. The variation between the poorest spark which will fire a mixture and the hottest "blaze" obtainable by the use of a geared-up magneto is in any case only the smallest fraction of a horsepower, and the motorist who imagines that his new magneto will take him up a hill on high gear that he used to take on second with his old coil, is either the victim of a delusion or has had his first system improperly timed.

Gas and Ignition Troubles Much Alike—Another point which I have mentioned is the frequent confusion of carbureter and ignition troubles. This is especially frequent on two-cycle engines, where the mixture is inherently poor, and requires excellent carburation. I cannot recall how many cases of ignition trouble I have cured by an adjustment of gas and air, but there have been a great many. I have found a very safe plan to adopt in case of trouble to be to test the spark at the plugs, and if it is all right, to get after the carbureter. This will lead to the trouble nine times out of ten.

Fixed spark ignition is a practice which has been more or less tried out in the automobile field, and is considered by some to be eminently satisfactory. To my mind, however, the trifling advantage obtained by elimination of hand adjustment is more than offset by the unquestionably greater wear and tear on the engine. It is entirely impracticable with a coil system, due to the fact that the lag of the vibrators, as well as of the coil, will retard the spark more and more as the engine speed advances, and at just the time when it should be considerably advanced, it is very much retarded. This leads to heated and warped valves, boiling out of water in the radiator, and deposits of carbon, as well as the material reduction of engine speed and power. These facts apply, although in a less degree to fixed magneto ignition, and one prominent concern manufacturing taxicabs, after trying out this system and building cabs for one year with this equipment, found it advisable to again adopt the hand control system. A very interesting discussion on this point was brought up at a meeting of the Society of Automobile Engineers last spring, and the general consensus of opinion at that time seemed to be that the advantages gained by fixed ignition were decidedly dubious.

Engine Speeds Up on Magneto?—Following along these lines of spark timing, I wish to comment on one of the most fallacious arguments I have ever heard advanced. It is the statement of the man who says: "I have just proven to my own satisfaction that the magneto gives more power out of the same gas than the coil. The way I did it was this—I let the engine run idle at a low, moderate speed on the coil, and then without touching anything else, I switched over to the magneto. The engine picked up right away, and ran at a much faster speed." The reason for this extra speed is very obvious, where the circumstances are considered. In the first place, the same advance lever operates, as a general thing, both the magneto and the timer. Now it is very seldom that the driver advances the spark as fast as it really should go. This is due to habit; he has become accustomed to carry the spark a trifle low in order that a momentary slowing of the engine shall not cause pounding. Thus it is that when the magneto is switched on, the effect produced on account of the lack of lag in magneto spark timing is to advance the spark and naturally the engine speed is increased. It is probable that the magneto would naturally increase the engine speed five to ten R.P.M. on account of the nicely synchronized spark which the magneto delivers, but the difference would probably not be appreciable.

These erroneous conclusions and assumptions without doubt have arisen from the fact that the ignition of an automobile engine is a part governed by different principles from the rest. They are, nevertheless, a very annoying factor of the ignition business, as any coil or magneto manufacturer will attest.

DEVELOPMENT OF THE SHOCK ABSORBER

By EDWARD V. HARTFORD

THE problem of designing a suitable shock-absorber for automobile springs first claimed my attention in the spring of 1899. I was in Paris at the time, and went out to Versailles to see a motor tricycle race. More interest was being taken in these than in automobiles, as they were faster. The race was won by Marcellin, beating Baras, who previously had been well established as the motor tricycle champion. When I looked at Marcellin's tricycle, a Darracq, equipped with a two-cylinder 12-horsepower Buchet motor, I noticed that the fork was entirely different from the ordinary one. Marcellin informed me that it was *la fourche Truffault* (the Truffault fork) and was a great invention. I then turned to Baras and inquired of him how Marcellin had come to beat him. He replied: "It's that Truffault fork. In my last race, which was partly over cobblestones, I used it, but as this race was over a road like a billiard table, I thought I would do better without it. However, I will never race without it again." Baras' tricycle was identical with Marcellin's, with the exception of the spring fork.

The following day I looked up M. Truffault and found him in a humble little shop located near the Porte Maillot, building the Truffault fork. He was a man of about sixty years of age, of the pure type of the inventor, creating one thing and then bending his energies on something else, not sticking to one idea until he had established it on a firm basis. From his inventions he should have been a wealthy man and long since retired from business, but instead the manual labor he was even then performing had cramped and bent his fingers. Truffault actually invented the hollow bicycle rim which first made the light safety bicycle possible. He turned his invention over to a large manufacturer of bicycles who promised him a royalty of ten francs on every one manufactured. Truffault, his mind still bent more on improvements and new inventions, failed to take the necessary legal steps to protect himself, and the manufacturer, putting his conscience behind him, became a millionaire, while the royalties which were actually Truffault's were never paid.

I had the Truffault fork applied to my own 2¼-horsepower De Dion tricycle with the most gratifying results. Truffault and I became fast friends, and worked in unison on the problem of a shock absorber for the various types of suspensions that were being used on automobiles. Truffault had a complicated idea which required a somewhat radical change in the construction of the automobile, and I suggested the simple suspension which has been used with such success to the present day.

In the fall of 1900 I went back to the United States and tried to interest some one in the invention. I bought a 6-horsepower Oldsmobile and sent it over to Truffault to experiment with, and this car was the first to be fully equipped with a set of our shock absorbers. Before this, however, I had demonstrated it with a tricycle, but could get no one to take the matter seriously. Even some of the best automobile engineers of the day could not understand why we wanted to brake the action of the spring with friction, and thought rather we should put ball bearings all around to give the spring its maximum oscillation.

One exception was Thomas A. Edison, to whom I took my tricycle at his experimental plant at Orange, N. J. There I rode up and down over a series of 150-pound castings about eight inches in height. Mr. Edison seemed very much impressed, and it certainly looked as though he intended taking it up. However, I waited for days to hear from him in vain. A little later I met the New York manager of a large automobile company, and through him obtained permission to make a demonstration at their factory. As this seemed the turning point in the career of the shock absorber, I considered the circumstances of sufficient importance to go to the expense of bringing Truffault over from France. He remained at the factory for two weeks, as it was necessary to change the very stiff springs with which the car was equipped to a more supple set. When the job was finished and the shock absorbers applied, the factory testing force gave them such a try-out as few shock absorbers have received since, and Truffault assured me that he never again cared to go through the same experience. However, the demonstration was very successful, and a short time afterward the company made me an offer of $1,000 for the patent. Naturally we declined the offer.

The automobile industry in France at that time was much further advanced than in the United States, and shortly after Truffault returned to Paris he made arrangements with the Peugeot Company to exploit the invention. The Peugeot Company put them on its own cars and sold a few sets besides. The increase in the marketing of the device was very slow, however, until the late Leon Théry became interested and decided to equip his Richard-Brasier racer with them. He won a sweeping victory in the Gordon Bennett race that year, although his car was the smallest entered, and naturally the shock absorbers received much credit. Théry was able to pass over all road obstructions without shutting off his power, while the others were obliged to slow down materially.

At once all the racing drivers rushed to Peugeot to have their cars equipped with the shock absorbers, and from this time the business went on with rapid strides. In this country we placed an initial order for 25 sets with the Garvin Machine Company, and after this had been duplicated twice we opened a small shop on Hudson street, New York, in October, 1903. By May of the following year we were running night and day to supply the demand, and conditions have hardly changed since. Numerous imitations have sprung up, but at the start we had patented every deviation of the idea and were fully protected.

Test of Pierce Water-Cooled Motor*

By J. A. Luhrman and G. W. Woodward

IN all of the tests the air valves, both main and auxiliary, in the carbureter were controlled by the throttle only. The gasoline needle valve, however, was adjusted for four different positions in the runs at 10, 15, 20, 25 and 30 horsepower at 1,000 and 1,250 r.p.m. The first setting was obtained by shutting the gasoline supply down to a minimum, and still carrying the load without back-firing. The fourth setting was with the maximum amount of gasoline possible, but sufficient for carrying the load. Between these two extremes two points were taken. By this means the range of the carbureter for the correct setting of the auxiliary air valve was determined.

It was intended when the test was started to make an analysis of the exhaust gases and also to measure the air to the carbureter, but owing to an unexpected shortening of the time allowed for the test we were unable to do this.

As we had started on quite a long series of brake tests, we finished these first and then spent what time we had remaining working on the manograph. We obtained very satisfactory results for all runs except at maximum horsepower; then the manograph became troublesome and the cards taken were not satisfactory. However, the results taken were worked up and put in the thesis, more to show what would have been done if time had permitted than for any other reason.

The runs at maximum horsepower were made with the needle valve of the carbureter set for maximum power which could be developed at that speed.

Previous to the tests, the valves of the engine were all checked over to see if they were timed correctly according to the figures given us by the makers. The valves were all timed so that they opened correctly and the closing was allowed to come where it would, as by several trials this seemed to be the best method to follow, since both adjustments could not be made on account of the cams.

A storage battery was used in all runs as the source of current for ignition, as the magneto did not seem to be able to operate reliably with a heavy load and high speed.

Method of Tests for Horsepower at 1,000 and 1,250 Revolutions—The tests were started as soon as possible after the engine was running under required conditions. On the first signal to start the test the gasoline gauge was read and the speed-counter snapped into place. The temperature of the jacket water in and out was also recorded. All readings were taken every two minutes and the speed-counter was always read exactly on the signal. The required brake-load was kept "floating" and the speed shown by the tachometer was used as a check on the reading of the continuous speed-counter.

Method of Testing for Maximum Horsepower—Five men were required for these runs, the fifth man reading the brake beam on a signal from the man taking the speed with the tachometer. The engine speed was kept constant by means of the brake, with the throttle wide open and the spark adjusted for the best results. In other respects, the runs were similar to those for varying horsepower at constant speed.

The main computations on each run were checked and compared as far as possible between the runs with the results of previous runs. Whenever a run appeared to differ to any extent from runs previously made, check runs were made, until the error was found or two similar runs checked. It was found necessary to make a number of check runs, especially at high horsepower and low settings of the needle valve of the carbureter.

Mounting of Engine—The engine was mounted upon a wooden frame and all of the necessary connections, such as water, electrical and gasoline, were made. The water supply was obtained from a tank which discharged the hot water through an overflow outlet near the top and the makeup water taken from the city mains. With this arrangement, by increasing or decreasing the amount of cold makeup water, the temperature in the supply tank could be maintained very nearly constant at any desired temperature. During the test, temperature of the jacket water was kept at a very nearly constant temperature and at such a temperature as would most nearly approximate the conditions of actual practice. The pump for circulating the water was calibrated under conditions of use so that the quantity of water circulated at any given speed could be approximately determined from the calibration curve. The water into the jacket was taken from the bottom of the supply tank and the discharge water was taken in at the top of the tank. The temperature of the cooling water "in" and "out" was ascertained by means of thermometers inserted into oil wells that were placed in the piping of the circulating system. The fuel was fed to the vaporizer by gravity. The weight of gasoline used during each run was determined accurately. The load was applied to the engine by means of a Prony brake. The flywheel was provided with a wide flange around the inside for the purpose of keeping a certain amount of water in the wheel and was kept cool by running cold water into it. The hot water was carried off by means of a scoop arrangement. The most satisfactory lubricant that was found for the brake was a rind of bacon or ham. By placing some of this lubricant between the wooden blocks of the brake so that it came in contact with the warm rim of the flywheel, the proper luhrication to give good results was obtained, for as the flywheel heated up, the grease ran more freely and so a balance was obtained, making it possible to keep the scale beam in very nearly perfect balance all the time.

All the runs were of 30 minutes' duration excepting for a few heavy loads, when at times the runs were made shorter, because of conditions at the time of the test. Readings of all data were taken in every case at two-minute intervals. A continuous counter was used to take the speed, and this was checked by means of a tachometer.

To start a run the engine was put under load and brought up to speed as shown by the tachometer, and conditions were allowed to become constant. At a signal from the timekeeper, the continuous counter was snapped into place by means of a spring and readings were taken of all values. By this method of procedure any error that might be introduced by the suction of the engine upon the fuel tank was canceled. The specific gravity of the fuel was tested for each new lot of gasoline placed in the tank. Mobile oil was used in the lubrication system and gave very good results.

During the test the engine was run without a muffler, owing to the long exhaust pipe used; it was thought that this would have practically the same effect as the muffler. The exhaust pipe, or manifold, on the side of the cylinders became very hot during a run at heavy loads, and this was cooled by means of an air blast from an electric fan which was temporarily mounted on the engine frame beside the exhaust manifold.

The temperature of the jacket water was kept as far as possible constant at 110 deg. Fahr., to obviate any changes in thermal efficiency due to the variation of the jacket water tem-

* Paper read at semi-annual meeting, Society of Automobile Engineers, Chicago, August 5-7, 1909.

perature; it was found that this temperature affected the results to quite a considerable extent.

The object of the test was to ascertain the following:

1. The fuel consumption and the economic thermal efficiency at constant speeds and varied horsepower output at various settings of the needle valve in the carbureter.

2. The fuel consumption and economic thermal efficiency at the maximum horsepower output and varied speeds with respect to the needle valve settings.

3. The mechanical efficiency and maximum compression pressures from the manograph cards.

4. To ascertain the fuel consumption for a slow no-load run.

Some Details of the Engine—The engine under test was made by the Pierce-Arrow Motor Company, of Buffalo, N. Y. It is of the vertical type, six-cylinder, water-cooled. Both the inlet and the exhaust valves are mechanically operated by means of gear-driven cams and lifting rods. The cylinders are cast in pairs and have a bore of 3 15-16 inches and a stroke of 4 3-4 inches. The water-jacket valve chambers and cylinder heads are all cast integral with the cylinder proper. The inlet valves are located on one side of the cylinder and the exhaust valves on the opposite side. The springs closing the inlet valves are weaker than those on the exhaust. All the valves are interchangeable and have cast-iron heads with 45-deg. seats and steel stems. They are operated by two sets of cams on separate camshafts, both located within the crank chamber. The push rods operating the valves are fitted at the lower ends with hardened steel rollers of large size and moving in renewable bronze guides.

The pistons, which are accurately ground, are made very light and with webs to strengthen the wrist-pin lugs. They are fitted with four piston rings.

The wrist pins are of nickel steel, case-hardened and ground, and are fastened to the wrist-pin lugs by means of taper-set screws.

The connecting rod is of the marine type, forged of steel and fitted with phosphor-bronze bushes at both ends. The wrist-pin bearing is made extra long. The crank-pin bearing is adjustable for wear.

The crankshaft is a solid forging of nickel steel and is supported on seven bearings which are provided with adjustable bronze bushes. Both the crank-pin journals and the main crankshaft journals are of liberal length and diameter, to insure cool running and long wear, and they are accurately ground.

The crankcase is cast of very tough aluminum alloy in two halves, being divided in a horizontal plane through the center of the crankshaft. All the crank bearings are entirely supported by the upper half of the casing and the lower half acts only as a dirt cover and an oil well. When the latter is removed, free access is obtained to all the crank bearings for inspection and adjustment.

The camshaft gears are located at the forward end of the engine, outside the crankcase, and are protected by a special oil-tight cover bolted to the crankcase.

The magneto spark-plugs are screwed into the side wall of the inlet valve chamber and the battery spark plugs are screwed into the top of the cylinder near the inlet valve opening.

How the Lubrication Was Effected—Lubrication is effected by means of a gear-driven oil pump located on the exhaust side of the engine. It is operated by a worm gearing on the camshaft. This pump draws the oil from the pit in the crankcase and forces it into the reservoir placed immediately above the exhaust pipe. From this reservoir a copper tube leads to each of the crank-shaft bearings. There is a removable wire gauge screen in each of these pipes to remove any sediment that may collect. The crankshaft journals and the short arms of the crank are drilled through their centers and the crankshaft is also provided with radial holes at the center of the journals so as to provide a passage for the oil from the main journal bearings to the crank-pin bearings. There is a continuous flow of oil from the reservoir to all the bearings on the crankshaft, the oil being carried from the main journals and forced to the crank-pin journals by centrifugal force. The oil that works through the outer crankshaft bearings returns to the bottom of the crankcase from where it is again pumped up into the reservoir.

In cold weather the oil in the reservoir is kept warm and its fluidity increased by its nearness to the exhaust pipe. This also admits of a heavier and more viscous oil than when it is not heated.

The shape of the oil tank is such that no matter whether the car is going up hill or down all the bearings get an equal amount of oil. The makers claim to have had very good results from this system of oiling, and from what could be observed during the test, the system worked very well.

All About the Cooling System—The cooling water is circulated by means of a water pump of the centrifugal type, which gives a large flow of water through the jackets of the cylinders. The pump is attached to the engine crankcase, being positively driven by means of a gear, meshing into the exhaust camshaft gear wheel. The supply for the pump is taken from the bottom of the radiator and delivered into the water jacket of the engine at its lowest point. From the top of the jacket the water returns to the top of the radiator.

Venturi Type of Carbureter—The mixture to this engine is supplied by what the makers term "Our special automatic carbureter." It is of the Venturi tube type. The constant level gasoline chamber is concentric with the spray nozzle. This is in communication with the main gasoline supply tank. The float is of annular design and keeps the height of gasoline at the spray nozzle constant. This height is 3-16 inch below the top of the nozzle, the opening in which is regulated by means of a needle valve. The gasoline from the supply tank passes through a fine gauze strainer, which prevents water and dirt from entering. When the engine is running slowly, the throttle valve is just open and the auxiliary inlet reed valves are on their seats. The opening formed by the throttle valve is V-shaped, so that the suction of the engine induces a high velocity at this point. All of the air is taken in at the lower inlet and, coming from the proximity of the exhaust pipe, is warm. It passes up the contracted passage around the spray nozzle at a high velocity and vaporizes the proper amount of fuel. When the engine runs faster, the more intense suction opens the light auxiliary air reed valves, and when running still faster it opens the heavy reed valve also. This, it is claimed, insures a gradual increase in the supply of air to the mixing chamber. The entire mixing chamber is surrounded by a hot water jacket. The supply pipe to the jacket has a cock in it, which can be closed in hot weather, but should be full open in cold weather to secure the best results.

Two Independent Ignition Systems—The ignition of the engine is supplied by two independent systems, as shown by the diagram, Fig. 4. One system consists of a storage battery and individual induction coils. The spark plugs for this system are on top of the cylinders. The timing by this arrangement is effected by a commutator of the roller type and is placed on a vertical shaft between the second and third cylinders. The revolving roller is operated by means of a pair of bevel gears from the inlet camshaft. The order of firing of the cylinders is 1, 5, 3, 6, 2, 4.

The other system consists of a Bosch high-tension magneto. In this magneto, a shuttle armature rotates between the poles of two pairs of strong steel magnets. The rotation of this armature in the strong magnetic field results in the induction in its winding of a strong electrical current which reaches a maximum voltage twice in one revolution, or after rotating through an angle of 180 deg. The current which is produced by turning the armature rises by short-circuiting the primary circuit through a contact breaker and breaking the circuit at a suitable moment. A spark jumps across the electrodes of the spark plug at the moment of the breaking of the primary circuit, causing the explosion in the cylinder. As the arc-like spark can only be produced when the armature is in a certain position and also the ignition has to take place at a certain period during the movement of the piston, it is necessary that the armature shall be positively driven. In the case of a six-cylinder engine, it must rotate at one and one-half times the speed of the crankshaft. The armature is wound in two parts; one is a primary winding consisting of a few turns of heavy wire and the other is a secondary consisting of many turns of fine wire. The end of the primary winding is connected to the secondary so that the latter is a direct continuation of the former. The end of the secondary winding leads to a slip-ring, on which slides a carbon brush, which is insulated from the magneto frame. From the brush, the current is conducted to a connecting bridge fitted with a central carbon brush, and through the rotating distributor piece which carries a radial contact carbon to the distributor disk. In the distributor disk are embedded metal segments, of which there are six. During the rotation of the contact carbon, the latter makes contact with the respective segments and always connects the secondary with one of the contacts. Connected to the segments are sockets which serve for the reception of the contact plugs. These plugs serve as terminals for the cables leading to the spark plugs of the individual cylinders. From the end of the secondary winding the high-tension current is led to the respective cylinders, which are fired alternately; the current produces the arc, which causes the explosion, then returns through the motor frame and the armature core and back to the beginning of the secondary winding.

Manograph and Connections—The manograph used in these tests was a Hospitalier Carpentier, made in Paris, France. The position and arrangement of the manograph and connections are as follows: The manograph was mounted on a tripod at the side of the engine and protected from vibration by being fastened by strong wire to the floor. A flexible shaft, screwed to a stud inserted in the brake wheel hub, was led to the manograph. The shaft was supported by a bracket attached to the frame on which the engine was mounted. The try-cock in the top of each cylinder was removed and the hole thus made was fitted with a special fitting, to which was connected the tube to the distributing block. One-sixteenth extra heavy copper tubing joined each cylinder to a brass distributing block. The gas distributing block is made of a bar 1 inch square and 4 inches long. The block was fitted with seven cocks and one brass union. One cock was to give atmospheric pressure and the other six were connected to the cylinders, the idea of the design of the block being to reduce the gas volume as much as possible and to have an equal distance from each of the cocks to the inlet leading from the manifold.

A 1-8-inch ground brass union was used on the top of each of the cylinders and the ends of the copper tubes were silver soldered into the unions. The other ends of the copper tubes were silver soldered into the cocks on the distributing box. An electric fan fastened to the wooden frame of the engine cradle was used to keep the exhaust pipe and the copper tubes cool.

The connection between the manograph and the distributing block was made by a short length of tubing; all bends in the tubes were made easy so as to cut down friction, and, by having the length of all the tubes the same, to have equal friction in each tube. All passages could be shut off at the block by the system of cocks used. When a cylinder was being indicated the cock on the block was opened, giving direct communication to the manograph, with a very slight increase in volume beyond that of the tubing itself.

Principle of the Manograph—A beam of light from a small arc light is reflected by means of the prism so as to fall on a concave mirror, which in turn reflects the beam on a ground glass screen. The mirror frame receives a motion from the engine which causes the beam of light to trace a horizontal path on the ground glass, while a vertical motion of the beam is produced by the action of the gas pressure on a diaphragm, which is connected to the mirror. The resultant of these two motions gives an indicator card.

Manograph Details—The flexible shaft comes up underneath the front of the manograph and terminates in a small gear. Another gear of the same size meshes with gear. The bearing for the first gear is in a brass worm gear, which may be revolved by means of an adjusting screw around the second as a center. It is thus made possible to produce a rotation of the one gear, while the other remains stationary. In this way the position of the shaft relative to the beam of light can be changed.

A small stud is fastened in gear which acts as a crank and is connected by a short link to the lever, which is pivoted to the frame near its center. The free end presses against a short pin, which in turn presses on a horizontal leg of the mirror frame. The mirror is supported on a right-angled frame which rests on three points. The point at the apex of the frame is stationary and acts as a pivot on which the frame rocks. The vertical leg of the frame rests against the pin which is in contact with the reverse side of the gas pressure diaphragm. Considering one of the pins stationary, any motion of the other pin will produce a rocking motion on the fixed pivot and the stationary pin. By means of these two motions at right angles to each other there is produced a resultant motion of the mirror frame about the fixed pivot. The mirror frame is held against the three pins by means of two strong, flat springs. The frame of the mirror and the connecting mechanism were made of hardened steel to reduce the wear and they were also of very light construction, the latter to reduce the inertia effects. The mirror is ground concave with its focus at the ground glass screen.

The gas diaphragm is a circular plate of thin steel supported at its circumference by being pressed against a ground seat by means of a brass plug. The plug is cut away, leaving a recess connecting with the tube from the distributing block. As all the joints are ground, the recess is airtight. A small hole is drilled back of the diaphragm into the recess to keep the pressure atmospheric.

This mechanism described is fastened to one end of a wooden box, the glass screen being at the other end. On one side of the box near the screen end is screwed a tube, supporting on the end inside the box a small ground-glass prism. The axis of the prism is vertical and is fitted with a small rod for adjustment if desired. On the other end of the tube is placed a framework supporting a small hand-adjusted direct-current arc light. Inside the tube, a tube of small diameter is placed, having the outer end closed by a diaphragm, through the center of which is drilled a very small hole. On the outside of this diaphragm a small shutter was arranged so as to screen the hole. The shutter was fitted with a spring so that the hole was nominally closed except when a card was being taken. The shutter was operated by a card. Adjustments were provided so that the center of the arc could be kept in the same horizontal plane and in line with the hole in the diaphragm. The plate holder was held in place by a brass spring. Direct current at 110 volts was used to supply the arc light, the power regulation being obtained by a bank of 16-candlepower lights connected in parallel with each other, but in series with the line.

Adjustment of the Manograph—In a proper setting of the manograph for a given speed there are two factors to be considered—first, the lag of the flexible shaft, and second, the lag of gas pressure in a small copper pipe. These were overcome by cutting the spark off of one cylinder and indicating the resulting cycle by means of a weak diagram (5 kilograms). The instrument was then adjusted until the maximum point of the compression line accrued at the end of the stroke, as determined by the horizontal travel of the beam of light. The expansion line retraveled as nearly as possible the compression line, as seen by the lines on the ground-glass plate. The speed was kept constant at the desired number of revolutions during the setting.

Taking of Indicator Cards—The beam of light as thrown on the ground-glass plate was photographed on stiff bromide paper inclosed in a double plate holder. A small shutter similar to that on a kodak was fitted to the diaphragm in front of the arc light and actuated by means of a card. A dark room was used which was situated in the gas-engine laboratory and provided with all conveniences. All the cards were developed immediately after being taken, so that duplicates could be made if necessary. In taking cards the manograph was adjusted as described above, then a 25-kilogram diaphragm substituted for the 5-kilogram diaphragm and a cylinder indicated and cards photographed.

Method of Obtaining M. E. P. Cards—Cards were all planimetered and the mean ordinate determined by dividing the area by the length. The mean ordinate thus obtained was scaled off by means of dividers on the calibration curve corresponding to the diaphragm used. The mean effective pressure determined by this method was reduced to pounds per square inch by multiplying by 14.22, and this mean effective pressure was found on the abscissa of the curve showing the indicated horsepower per cylinder against mean effective pressure in pounds. Going vertically upward on this sheet until the line corresponding to the speed in consideration is reached, then across the sheet horizontally, the indicated horsepower may be read directly. This series of curves was computed from the constants of the engine.

Gasoline Analysis—The gasoline used in the test was analyzed by Dr. Lundell, of the Department of Chemistry, Cornell University. The sample analyzed was selected by taking numerous samples of the gasoline from time to time out of the bottom, middle and top of the gasoline tank, then thoroughly mixing them.

The heating values as determined by a Junker calorimeter were as follows:

Higher heating value = 19,798 B. T. U. per pound.
Lower heating value = 18,700 B. T. U. per pound.

Sample Computations for Run No. 1—10 horsepower at 1,000 r.p.m.

Gasoline consumed in 30 minutes = 4,320 cubic centimeters.

Specific gravity = .705.

Since 4,320 cubic centimeters of gasoline were used and 1 cubic centimeter = .061 cubic inch, therefore, $4{,}320 \times .061 = 264$ cubic inches used.

As the hydrometer was calibrated with water at 60 deg. Fahr., and the weight of 1 cubic foot of water at 60 deg. Fahr. = 62.37 pounds, then the weight of gasoline = cubic inches × specific gravity × weight per cubic foot water ÷ 1,728 =

$$\frac{264 \times 62.37 \times .705}{1{,}728} = 6.72 \text{ pounds.}$$

B.t.u.'s supplied per hour = pounds of gasoline used × lower heating value of gasoline =

$$6.72 \times 2 \times 18{,}700 = 251{,}000.$$

Thermal equivalent of 10 horsepower.

$$\text{H. P.} \times 2{,}545 = 10.016 \times 2{,}545 = 25{,}460.$$

Thermal efficiency =

$$\frac{\text{Thermal equivalent of work}}{\text{B. T. U. supplied}} = \frac{25{,}460}{251{,}000} = 10.15 \text{ per cent.}$$

Pounds of gasoline per 1,000 revolutions of motor = pounds of gasoline used ÷ total revolutions × 1,000 =

$$\frac{6.72 \times 1{,}000}{30{,}050} = .2235 \text{ pounds.}$$

The volumetric efficiency from the card was determined by measuring the distance between the points where the compression and suction lines cross the atmospheric line, and dividing this distance by the total length of the card. The average volumetric efficiency from the cards of the six cylinders was taken.

The indicated horsepower of the engine was found by taking the sum of the indicated horsepower of each cylinder.

The pumping losses = the difference betwen the indicated horsepower from the indicator card and the basic horsepower =

$$18.75 - 10 = 8.75 \text{ horsepower.}$$

Mechanical Efficiency—The mechanical efficiency is the ratio of the direct horsepower to the indicated horsepower, and in this case =

$$\frac{10}{18.75} = 53.3 \text{ per cent.}$$

Horsepower Rating of Engine—The engine tested was rated on the A. L. A. M. horsepower rating, and according to this rating was a 36-horsepower engine.

On actual test at 1,250 r.p.m., which is below the rating, the horsepower obtained at the brake was 38.25, so that the engine was thus proved to be considerably better than the rating

Other Engine Data—Flywheel diameter = 18 3-8 inches.

Flywheel width = 5 3-4 inches.

Exhaust pipe: 13 ft. of 2-inch pipe; 6 ft. of 2 1-2-inch pipe.

Range of throttle segment, 0 — 22.

Range of spark segment, 1 — 14.

Length of brake arm, feet = 3.185.

LETTERS INTERESTING

COMPRESSION-KNOCKING

Editor THE AUTOMOBILE:

[2,023]—I have a four-cylinder 4 by 5 engine that is very noisy and is continually knocking on full throttle. The compression space is very small, less than 1-4 of the stroke. Would you consider it a change for the better to increase the compression space? If so, what proportion is considered best, according to the latest practice?

CONSTANT READER.

South Egremont, Mass.

Resolved into figures in such a form as to show approximately the compression ratio, the above is at once seen to be the cause of the trouble; that is, the compression is so much too high as to cause the knocking spoken of.

The compression figure is arrived at through a consideration of the ratio of the volume of gas drawn into the cylinder to the same gas compressed to a much smaller volume. The first volume is composed of two parts: that swept out by the piston, and that of the compression space. The latter is, also, the second quantity. In other words, the figure desired is:

$$\frac{\text{Vol. swept by piston} + \text{compression space}}{\text{Compression space.}}$$

The volume swept by the piston is the product of the area of the bore by the length of the stroke, in this case, 62.85 cubic inches. The compression space cannot be figured as closely, for the figures given are too indeterminate. Doubtless, the size of the chamber is greater than the cylinder, as to diameter. Usually this amount is 1-8 inch on each side, which would make the diameter 4 1-4 inches. Now the length of this chamber is given as less than one-quarter. of the stroke. This would be 1 1-4 inches. Taking a lower figure at random, of say, 1.2 inch, the volume of the compression space becomes 17.03 cubic inches. The ratio of compression is then

$$\frac{62.85 + 17.03}{17.03} \text{ which equals } 4.68.$$

Even if it be considered that the shape of the compression chamber is very complicated and 10 per cent be added to it to allow for this, the ratio still remains at the very high figure of 4.35. As the usual figure for this ratio is below 4 and the most usual figure as shown by the latest practice (resulting in a compression of 60 pounds cold) is nearly 3.5, this is seen to be too high.

While not the best way, this can be remedied by shortening the connecting rod, which would not change the piston displacement, but would add a portion of the cylinder bore to the compression space. As this is of a known diameter, the amount which the connecting rod is shortened will determine the ultimate compression. It may be figured thus:

$$\frac{62.85 + x}{x} = \text{the desired ratio, either 4 or 3.5.}$$

Taking the former, this becomes

$$62.85 = 4x - x = 3x,$$

from which x is evaluated as 20.95 cubic inches. Now, as the present volume, which will not be changed, is 17.03, this must be subtracted, leaving 3.92 cubic inches, which must be added to the compression space to make it give a compression ratio of 4. As this will be cylinder bore, divide by the area of that 12.57, and the result, 0.31 inch, will be the amount to shorten the connecting rod. Carrying through the same line of reasoning for the low ratio or 3.5, 0.64 inch is obtained. In view of the result to be obtained, it will be sufficient to shorten it 1-2 inch, which will reduce the compression pressure to about 65 pounds, a very good average figure, and one that will give more satisfactory results than the present ratio.

A FRIEND OF CHAIN DRIVING

Editor THE AUTOMOBILE:

[2,024]—In your August 19 issue, in answer to F. K. Green, of Louisville, Ky., in "Letters Interesting, Answered and Discussed," when speaking of cars with double chain drive, you say: "If one of the chains on a double chain driven car breaks, it is helpless and must be towed home." This is a question that I have explained to several friends. If there are not parts or tools in the kit to repair the chain, the free jackshaft can be bound to the frame or radius rod to keep it from turning. The car can then be brought home on the other chain. In such a case, however, it must be remembered that the differential works all of the time, making the gear ratio in this case half of what it would be otherwise. Nothing higher than second speed should be used as it would strain the gears of the differential. The advantages of a double chain drive are the great strength for the light weight and the lessened loss of power through friction. Thus, in case the chain is bent, any country blacksmith can straighten it. The shaft drive is the most silent drive used to-day, and for that reason many prefer it.

RICHARD S. JOHNSON.

Altadena, Cal.

This subject was covered very thoroughly in the issue of Sept. 2, which you have apparently missed. In a letter from A. Wilson Dods, and the answer to the same, the whole matter was covered. As to the point brought out above, "any country blacksmith can straighten it," this is very true, and equally as true of any part of a shaft-driven car. That is, it would be just as safe to trust the country smith with a bent shaft, if you ever happened to have one bend, which is highly improbable, as it would be to trust the parts of a nickel-steel chain to his tender mercies. If you look into the matter of relative merits of the two forms of drive you will find that silence alone would never have placed the shaft on the high pedestal which it occupies to-day. Other eminent and more valuable qualities, such as lubrication, lessened care, reduced wear, and with these, lowered cost of repairs, have had as much of a bearing on the result as exemplified in the comparative number of the two types to be made for next season, as has the matter of superior quiet, of which you speak so highly.

ENGINE HARD TO START

Editor THE AUTOMOBILE:

[2,025]—I had an experience recently with a two-cylinder opposed, engine under the seat, car three years old which I should like to have explained. At the time this car was overheating badly, so that we had to fill up with water every 20 miles or so. It was also rather low on power, so that several times we stalled the engine. Now, whenever the engine stopped in this way, it positively would not start until it had been cooled by pouring several buckets of water into the radiator with the cylinder cocks open. After being well cooled and getting a five minutes' rest, the engine would start off again quite nicely; otherwise no amount of cranking would get more than an occasional snort.

We have since cured the overheating pretty well, but if you can explain what caused that difficulty in starting, so as to be prepared for some future emergency, I will be much obliged.

C. D. P.

New York City.

It would appear as if the overheating was the cause of the hard starting. The cylinders get so hot that the pistons are upon the point of seizing, this being a continuous performance, but nothing happens until you stop, when the boiling water causes the pistons to seize momentarily. Cold water into the circulating system and a long rest, such as you describe, would cool the walls off very materially, causing a drop of perhaps 45 to 50 degrees in the time you mention. This allows the pistons to free themselves, so that the engine may be started. It is just barely possible that some flaw in the fuel supply system causes a copious supply of fuel while the engine is turning over, and, consequently (being opposed), vibrating very much, which is not in evidence when the engine and car are standing still.

To remedy the overheating, put a larger driving and a smaller driven gear on the pump drive so that the pump will be driven faster. This will circulate the water at a higher speed and thus carry away more heat, since the amount of heat carried off by the cooling water varies directly with the amount of water circulated. Thus, if the present gears happen to be each of 6 pitch and 18 teeth, changing the driver to 21 teeth and the driven gear to 15 teeth will leave the center to center distance unchanged at 3 inches, and will increase the pump speed by 40 per cent. If this is not sufficient a later change to a driver of 24 teeth and a driven gear of 12 teeth will also leave the center to center distance unchanged, but will change the speed, increasing it 100 per cent over the first arrangement and 43 per cent over the second method of gearing.

Driving the pump faster will cure your trouble unless the pipes are clogged up. In fact, it would be well to go to the trouble of examining these before making the other change, that is changing the speed of the pump by altering the gearing.

ANSWERED AND DISCUSSED

SIX-CYLINDER RADIAL ENGINE

Editor THE AUTOMOBILE:

[2,026]—Will you please advise me about a problem which has troubled me for some time. It is relative to a two-cycle engine of the differential piston type, which I am going to build. In this type of engine, why wouldn't the cylinders take gas from the mixing chambers if the inlet pipe from all chambers was a single pipe forming a circle (the six cylinders being arranged radially, so as to form a circle around the crankcase)? I want a very light weight engine, as I wish to use it in an aeroplane. As near as I can see, the mixture would be the same. I would have to use a suction valve on each chamber and a check valve between each chamber and the working cylinder.

Would aluminum be correct for an exhaust pipe? The enclosed sketch shows the arrangement, and I wish to know if the firing order would be as I have marked it, that is, 1, 2, 3, 4, 5, 6. In other words, will the radial two-cycle, six-cylinder engine fire around the circle of cylinders in regular order? Is the compression chamber as shown of the proper size?

The connecting rods are to have a pin the same size as the wrist pin, connected to a main connecting rod. What I mean by main connecting rod would be the same as any other engine, only the other five rods would have pins to connect them to the main rod bearing. Would the rods be correct if I had a very light forging driven in each end of a light steel tube and brazed? I intend making each end solid bearing, with no take up for wear, with pins 5-8-inch in diameter. Can I get good results with make and break spark, like the Locomobile?

N. F. GILLENWATERS.

Arbuckle, Cal.

In the first matter of the size of cylinders which will be correct to use, it is noted that you wish to use a 3 1-2-inch main cylinder, 5 1-2-inch differential cylinder, and a 3 1-2-inch stroke. Upon first thought it would appear as if the area of the larger or differential cylinder bore should equal that of the smaller or working cylinder, the stroke being equal in each case. This would result in equal volumes. But the volume in the larger cylinder is compressed and then delivered to the working cylinder, this compression being the one and only advantage of this type. Now, if the area of the two cylinders, or more correctly, the volume, is made equal, the one cylinder will compress the charge and deliver it to the other, where it will then be free to expand to its original volume; in fact, taking into account the volume of the connecting pipes or passages, to slightly more than its original volume. So nothing will be gained.

From this we arrive at the conclusion that the ratio of the two volumes must be such that the differential delivers to the working piston a charge of compressed gas, which, *at that pressure*, is of a volume equal to or greater than the volume of that cylinder. It is then necessary to take into account the compression pressure and the resulting volume.

Now, the compression follows closely if not exactly along the adiabatic line, for which the experimentally determined figure of 1.35 is used. That is, the relation between the volume and pressure is expressed by the equation:

$$\left(\frac{V_1}{V_2}\right)^{1.35} = \frac{P_2}{P_1}$$

which may also be put in the more convenient form

$$\frac{V_1}{V_2} = \sqrt[1.35]{\frac{P_2}{P_1}}$$

in which,

V_1 is the original volume,

V_2 is the final volume, or volume of compression,

P_1 is the original pressure, and

P_2 is the final or compression pressure.

To use this formula it will be necessary to assume the compression pressure, so let us select 60 pounds as the quantity. Then, this being gauge pressure, the absolute is 74.7. Atmospheric pressure varies at different elevations, but it will be safe to take it at 14 pounds. This will give a rough but very close average for the atmospheric pressure value. From these two, the ratio of pressure increase is:

$$\frac{P_2}{P_1} = \frac{74.7}{14} = 5.34.$$

From this and the previously given equation, the ratio of volumes is found to be 3.46. Now, as the final volume, V_2, is known, this being the volume of the final cylinder (3 1-2-inch diameter by 3 1-2-inch stroke), simple substitution and division gives for the volume of the differential cylinder 116.498 cubic inches. This will be a circular ring exactly 5 1-2 inches diameter, just as you had decided to use. The construction, as outlined, then, should give a compression of 60 pounds.

Every two-cycle cylinder fires on each one of the down strokes. Six two-cycle cylinders, then, would fire each on its own down stroke, making six per revolution, and requiring that the crank pins be spaced equally around a full circle; that is, one-sixth of 360 degrees apart, which is 60 degrees. Beyond this the order of the firing will be such as the crank is arranged to give. That is, if the pins are properly arranged, it is possible to get a firing order of 1, 2, 3, 4, 5, 6, as you wanted.

In the arrangement of the crankpins you will have the choice of either of two methods: you may have each rod end bear on the pin, as does the Adams-Farwell, shown elsewhere, or you may connect five of the rods to pins located on the sixth rod, as you

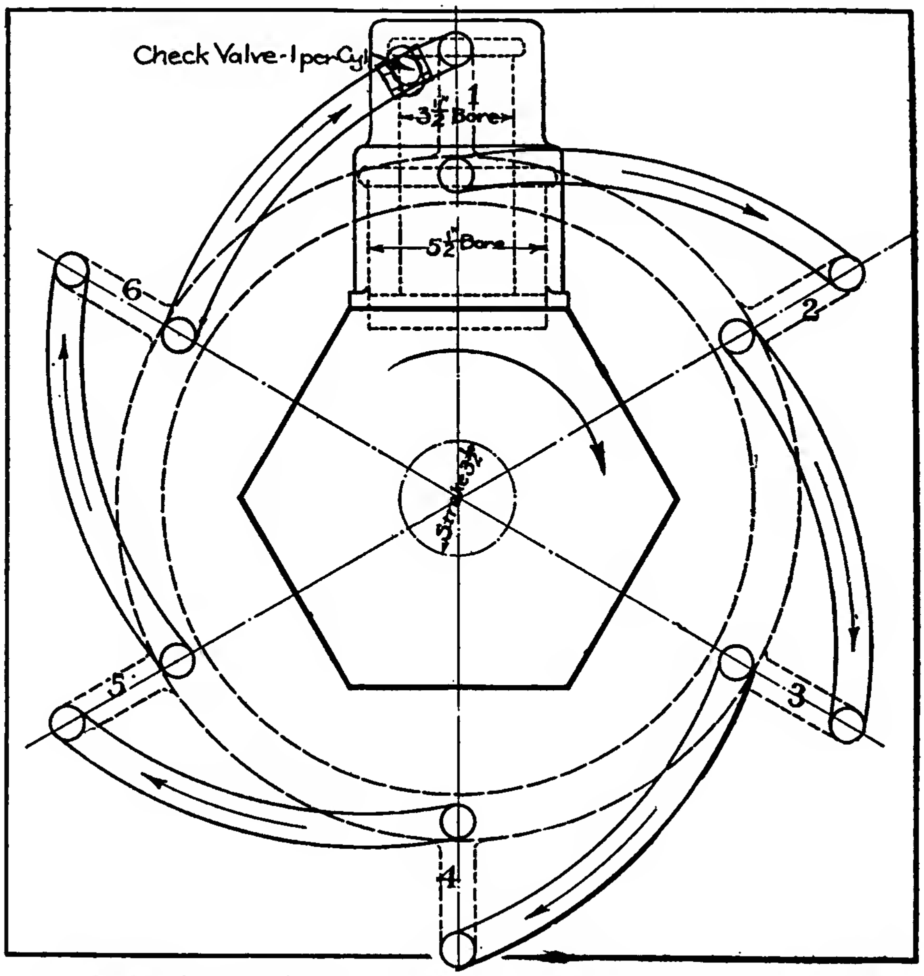

Diagram Showing Writer's Piping (Dotted) and Our Suggestion for This in Solid Lines suggested that you would do, as is done on the Esnault-Pelterie (French) seven-cylinder aeronautical motor. The Adams-Farwell crankshaft and connecting rod outfit shown belongs to a five-cylinder engine in which the cylinders revolve, but the company also makes a seven-cylinder of the

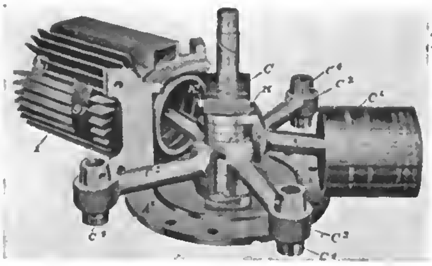
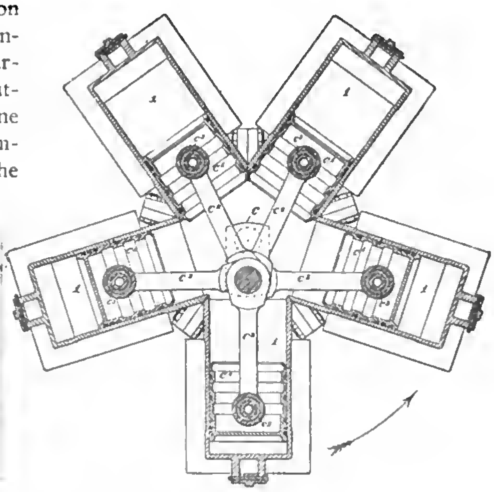




Method of Attaching Connecting Rods on Adams-Farwell Aerial Motor

same form and similar construction. In the Esnault-Pelterie you will notice that the cylinders are set in two rows, one back of the other, there being four in the front row and three in the second. This arrangement solves the crankshaft problem; this particular engine having a two-throw shaft, the front set of pistons and rods operating on one pin, and the back set of three operating on the other. In this engine the cylinders are stationary, so that it bears some resemblance to the one which you are building. A glance at the construction will show you that these cylinders being four-cycle, the firing must jump from the front set to the back.

Thus the firing order is very apparently 1, 5, 2, 6, 3, 7, 4, each cylinder in the front row firing on the part of the down stroke of that crank to which they are attached, while the three cylinders in the back row and attached to the other crank do the same thing.

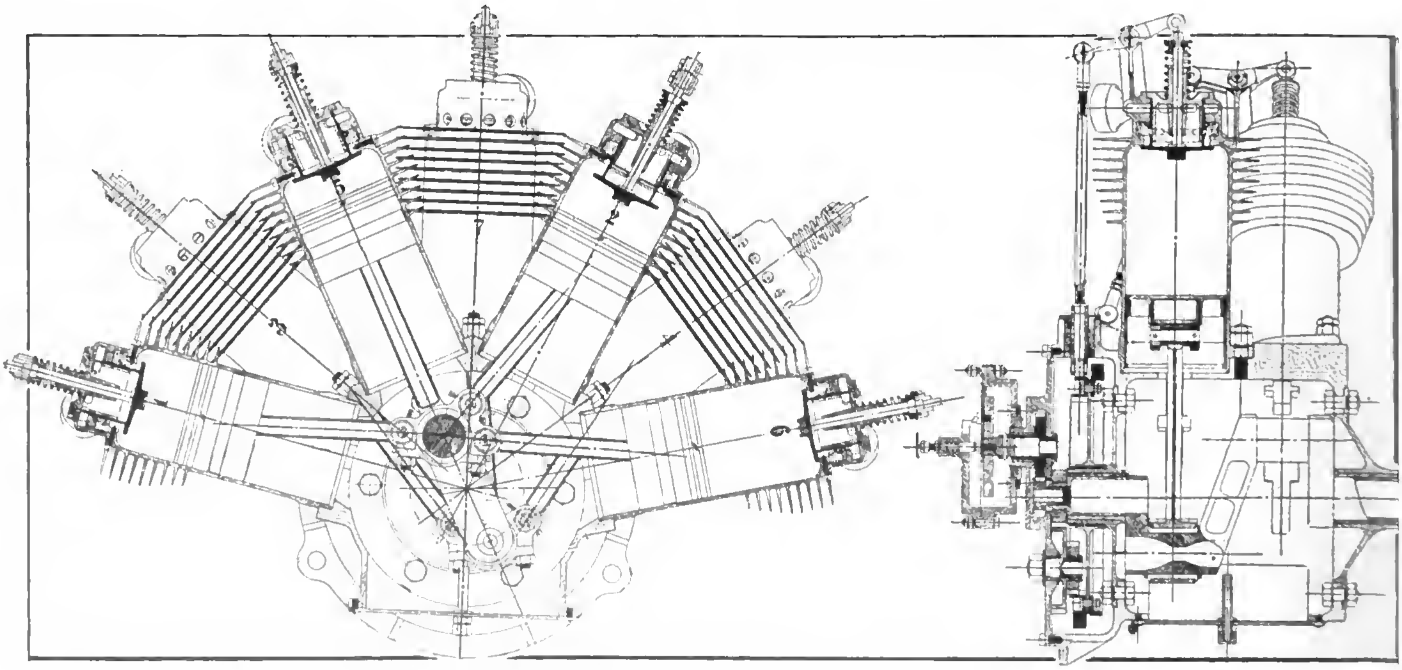
As far as make-and-break ignition is concerned, it is only fair to say that if you follow the Locomobile practice, and do as well as they do with it, your ignition system will give you no trouble. As a matter of fact, we do not know of any aeroplane engines now in use upon which this form has been tried.

The arrangement of the piping to supply mixture to the various cylinders as you have outlined it is not good, neither is it correct. If you arrange your crank so as to fire the cylinders around the circle in natural order, that is, 1, 2, 3, 4, 5, 6, the piping should consist of individual pipes from each compression cylinder to the working cylinder which fires next in order. In short, pipe from No 1 differential piston to No. 2 working piston, from No. 2 differential piston to No. 3 working piston, etc. The pipes will then take the form of portions of a circle and all will be alike, each one with one check valve in it, to account for and take care of the fact that this method furnishes gas to an ascending piston, which may drive part of the charge back, if a check valve is not used.

It is not advisable to use aluminum for exhaust pipes, or elsewhere, if it is liable to be subjected to great heat. Steel tubes may be used for connecting rods, with machined drop forgings set into the ends, pinned and brazed. This requires very careful workmanship, for if the pins be omitted the only strength the rods will have in tension will be the brazed joint. As brazing is usually a doubtful operation, this must be watched closely and carefully.

The use of a solid end bearing is, however, to be deplored since it gains nothing and is a distinct disadvantage. That is, you would not save any weight, which, we take it, is the idea. The reason why you won't save any weight is this: to get the rod on and off of the crank pin, it will be necessary to have it split and have bolts to hold the two halves together. Placing a few shims in between the halves, which shims would not weigh any more than a corresponding thickness of either rod or bearing metal, would thus add nothing. On the other hand, if you should ever try to sell these engines, the fact that the bearings were not adjustable for the inevitable wear would militate against them very much. All this is said with the mental reservation, unless you use ball bearings. From your letter which is fairly explicit, we believe that this was not the intention.

To speak of aluminum again, this can be used for inlet pipes, and when so used saves some weight, although, without a doubt, there is too much stress laid upon this weight-paring process in aeroplane engines. If the weight was not pared down so far, they would be more reliable than is the case at present.



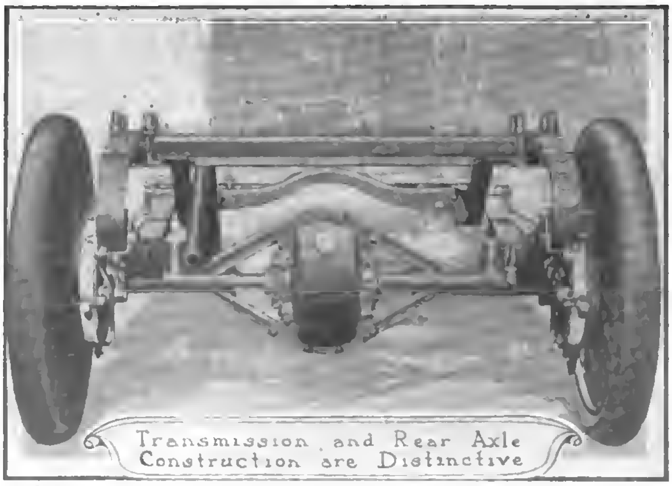
Section Through and End View of Esnault-Pelterie Aeroplane Motor, Showing Another Method of Attaching Connecting Rods

DISTINGUISHED as they are by the "white line around the radiator," as well as other very evident marks, the cars made by the F. B. Stearns Company, Cleveland, Ohio, are worthy of notice wherever they may be. This striking mark only serves to allow of ready recognition, for the sterling merit of the product of the Ohio factory would bring it attention anywhere. Coincident with the details of the models for the ensuing year, this company announces one very praiseworthy change. This is not in the nature of a mechanical alteration, but a policy. It is the abandonment of the method of speaking of the cars as yearly models. This practice, which has outlived its usefulness, for the changes now are so slight from year to year as not to change the car as a whole, at least not sufficient to warrant calling it a different model, will doubtless be followed by a number of other concerns now that a start has been made.

In the future the Stearns cars will be put through the shop the same as in the past, in groups or series of a given number. So, to give the cars a distinguishing mark, where that becomes necessary, they will be called "New Series." The present subject matter deals with the "New Series" 15-30.

This small car will have very few changes, among which may be noticed the reinforced three-quarter elliptic rear spring suspension, multiple disc clutch, and an alteration in the frame to go with the change in the springing, and bring out its best qualities. This car, which made its début last year, faces the present selling season with a most excellent record behind it. Built in toy tonneau, touring, limousine, and landaulet body types, the small member of the Stearns line met with instant success and at once established itself as fully worthy of the name and the "white line." The distinctive features at once become popular.

In general design this car follows the same structural and mechanical features of the other higher-powered models, and the same high-class material is used. While no mention is made of the fact that some of the materials are brought from abroad, it is no secret that the whole of this country and Europe is scoured to secure the best in this line. That success attends these efforts is told best by the record of the car in steady service, in road races, hill climbs, and track races, under all of which conditions it has acquitted itself with much credit.



Transmission and Rear Axle Construction are Distinctive

Motor Details Are of Unusual Interest—The motor is of 4 1-2 inch bore by 4 5-8 inch stroke, and differs from the larger Stearns engines only in the relative size of parts and the casting of the cylinders in a unit, or *en bloc,* as it is called. In this, it is one of the largest sized engines to employ this form of simplified construction, which is now being used to the exclusion of everything else in continental Europe. By means of this construction many combinations of parts are possible, which in turn allow of the elimination of still other parts. This latter feature simplifies the water, carbureter and exhaust piping and gives greater compactness, fewer pieces and more accessibility to parts. It has ball-bearing mounted crank and camshafts. All valves are of the same size and on one side; centrifugal water pump and other mechanical details of exactly the same type as on former motors.

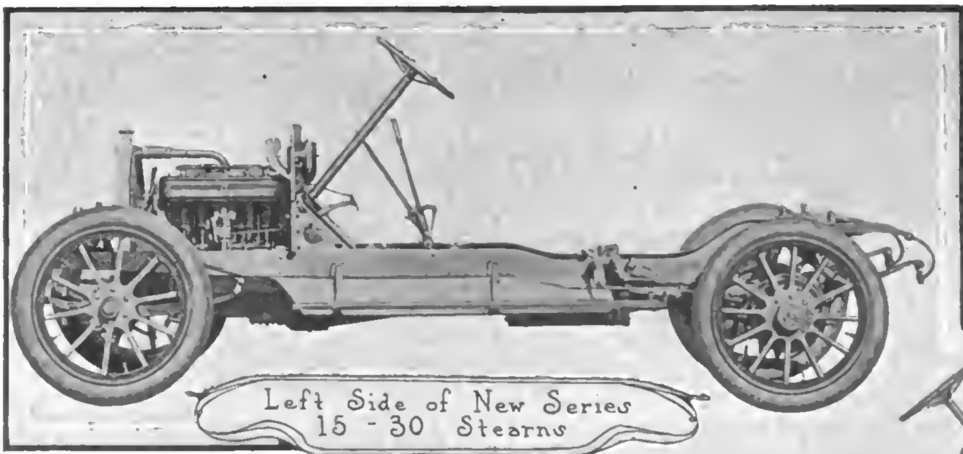
Lubrication is by the constant circulation system now in general use. The reservoir on the bottom of the crankcase supplies oil to a gear-driven pump. The pump discharges the oil on the connecting rods and is drained through screens back into the reservoir. The system is simple, but highly effective.

The carbureter is the same type which has been so successful on the 30-60 model. It consists of practically two carbureters, fed from the same float chamber and actuated by the same throttle lever. The mixing chamber is divided in such a manner that for a small opening of throttle, the small jet only is exposed to the suction of the motor and all of the gasoline used to develop up to 15 horsepower is supplied through this one nozzle. A further opening of the throttle brings into action the larger part of the carbureter with its gasoline jet, and a greater supply of fuel is available, sufficient, in fact, to produce more power than the maximum rating of the motor. Correctness of mixing proportions and economy of gasoline are assured by this arrangement. It accounts in part for the noted smooth running flexibility and power of the motor.

The ignition is by the Bosch dual system, consisting of an arrangement of high-tension magneto and single vibrator coil, whereby with a single set of spark plugs a double system of ignition is obtained. A simple switch on the dashboard permits running the motor either on the battery or magneto. Being directly in front of the driver it is an easy matter to change from one to the other.

Preference Given to Multiple Disc Form of Clutch—The clutch is of the well-known multiple disc type. Its characteristics—smoothness of operation, reliability and simplicity—which have made for the adoption of this type of clutch by the best automobile builders, are assured in this car by correct design and workmanship. The adoption of this form of clutch may possibly foreshadow the more extended use of this form in the future on other cars, coupled, as it is, with similar reports from other equally high-grade factories. One fact stands out very prominently in the clutch problem, and that is the fact that whatever else may be said for or against this kind of a clutch, all admit that there is nothing to burn out or be injured. This makes it a very good clutch for a beginner to learn on.

A propeller shaft and one universal joint transmit the power from the clutch to the transmission, which is located on the rear axle, and of the special compact type originally used.



Left Side of New Series 15 - 30 Stearns

The transmission is of the selective type and gives three speeds forward and reverse. The gears are of chrome-nickel steel properly heat-treated and of liberal dimensions. The shafts are also of this steel, all mounted on ball bearings.

The rear axle is of original design and worthy of special note. It is machined from a one-piece drop forging of nickel steel. It has an open truss-like center portion of I-beam section which spans the transmission case top and bottom, while at the same time it serves as a support for the latter. The ends of the forging are turned to mount the wheel bearings. It is bored through the center to take the drive shafts which extend from the differential gears in the transmission through the axle to jaw clutches on the outer end of the rear hub. This gives an axle which is without a joint and supports the weight of the car entirely independent of the transmission. The transmission is relieved of all strain other than that of transmitting the power of the engine to the rear wheel. The whole construction is good in that it gives absolute protection for the driving mechanism from all road shocks and strains but takes such strains on a hollow axle which for strength and reliability is only equalled by the more common solid.

A torsion tube extends from the forward end of the transmission case to a pivoted yoke. This encloses the propeller shaft and its universal joint, and serves both as a torsion and radius rod.

This form of transmission arrangement, coming, as it does, midway between the more usual mid-location and the solidly mounted transmission on the rear axle, possesses some of the advantages of both, without corresponding drawbacks. Thus, the mounting is such that road shocks do not transmit directly to the transmission case, shafts, bearings, and gears, with the consequent destructive effect upon them.

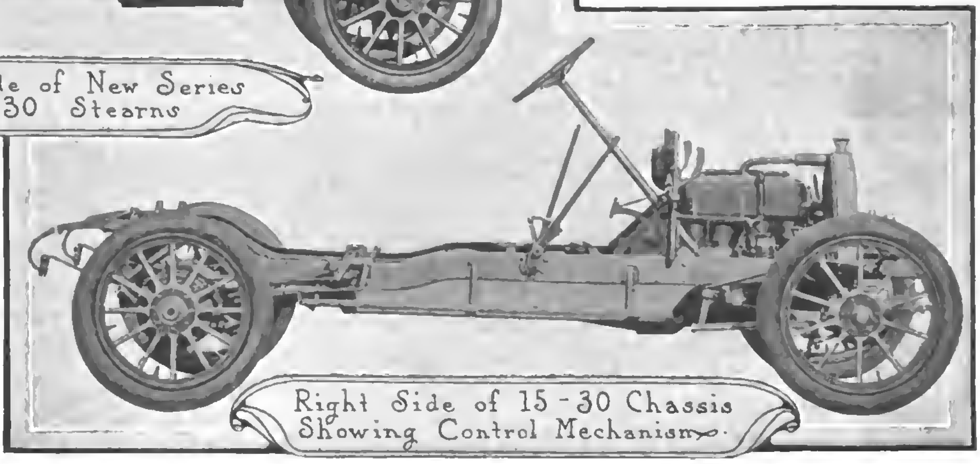
What the Frame Shows That Is Different—Coincident with the change in the rear springing the frame has been changed, the differences being intended to make the already easy riding car ride still easier. The frame is narrowed in front to permit a sharp turning angle; while maintaining the standard tread of the wheels this car will turn in a circle of 34 feet, a decided advantage in handling a car in narrow streets.

A double drop in the frame permits the mounting of a body of very graceful design with extremely low doors. The step from running board into the body is consequently very slight, and in service, where one gets in and out of the car frequently, as in shopping, this feature is particularly pleasing. A drop in the frame also lowers the center of gravity of the car, increasing its stability and one notices a greater sense of security when riding at high speed.

The spring suspension is of the semi-elliptic type in front, and of the three-quarter elliptic type in the rear. It is extremely successful and makes the car ride very easily and smoothly over rough roads.

With increased stability due to lowered center of gravity, lowered step, and easier riding, the change is seen to be worth while, involving, as it does, three good and very essential features.

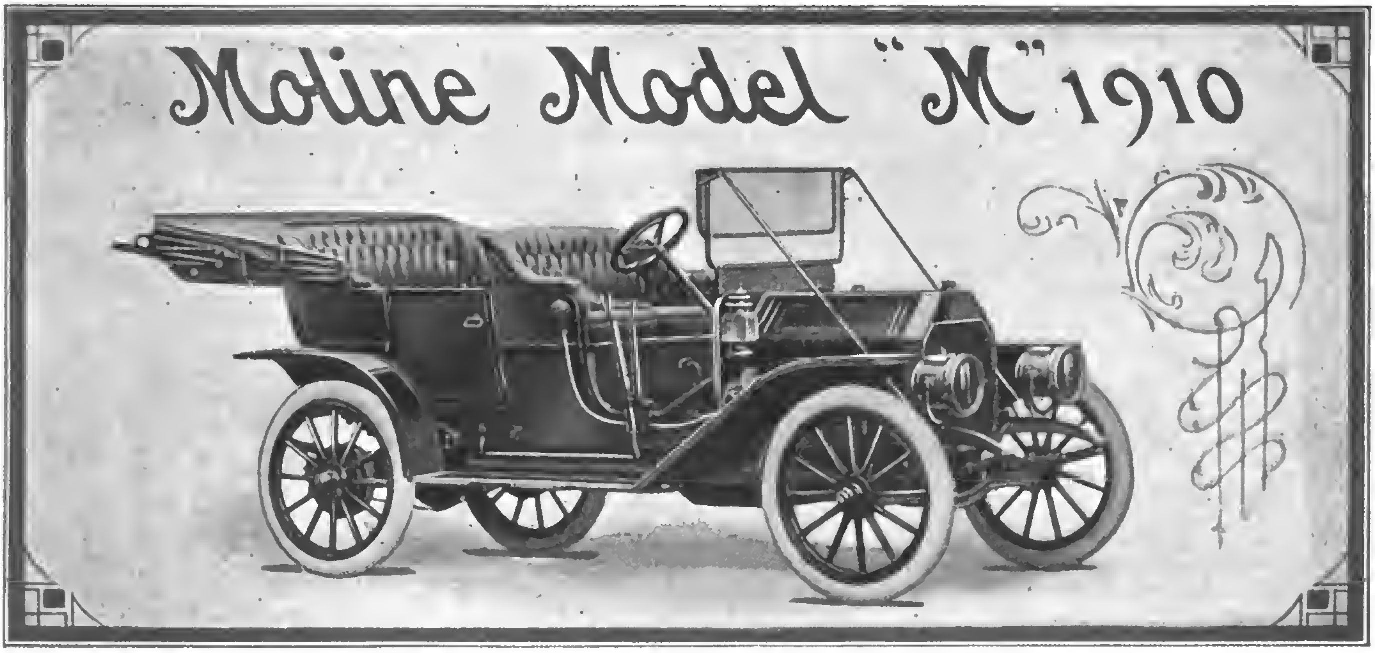
The brakes act directly on the rear hub flanges. The service or foot brake is a contracting band on the outside of the drum and is operated by a foot pedal in the usual way. The emergency brake is an internal expanding shoe, and is operated by a hand lever. Both brakes are fabric lined and easily adjusted.



Right Side of 15 - 30 Chassis Showing Control Mechanism.

The wheels, front and rear, are mounted on adjustable roller bearings. Continental detachable rims are now regularly supplied as standard equipment. These wheels are of 34-inch diameter, with 4-inch tires all around, thus making all wheels interchangeable. In case of trouble, the fronts may be changed to the rear and the rears placed in front. This is a very good point, and one well worth remembering.

Unchanged is the tread, which is standard at 56 1-2 inches, as is also the wheelbase, which remains at 116 inches. As previously stated, four body forms are built, of which the purchaser has a choice. These are the enclosed bodies, both limousine and landaulet; toy tonneau, which accommodates four; and regular touring car. The chassis price is $2,900, all bodies being extra, and the price of the same varies from $300 for a touring or toy tonneau upward to $900 for the spacious and well-appointed landaulet. While this seems a large price to pay for a small town car, the value lies concealed within the material and workmanship, which together go to make up a car that will last. It is said with truth of a high-grade car, that nine-tenths of it is concealed where the purchaser cannot see it. Repair bills show it, however.



TO enter the "$1,500 class" with a poor car would be folly for any manufacturer, but to enter the same with an unusually high-grade car, which has already scored a signal success in the Glidden tour, is to take front rank at once. Such is the case of the Moline Automobile Company, with Model M, which besides representing the utmost in value, will be featured as the leader of the Moline 1910 line. This will be made in several styles of body, on the one chassis, the bodies comprising the regular five passenger touring car, four passenger toy tonneau, a single rumble seat roadster, and finally a new type, in the beetleblack roadster. The touring car still seems to be the principal type and that is an unusually graceful body with pleasing lines, roomy spaces making for ease and comfort, the whole making up into an admirable looking car. A long wheelbase, adequate springing, and large sized wheels give easy riding qualities without which all other qualities are worthless.

Experience Back of the Power Plant—A bang-up, first-class power plant is insured by the years back of the construction. Although comparatively late comers into the automobile business, this company, in its big plant at E. Moline, Ill., has been building gas engines, both stationary and for traction engines, for a period of a dozen years prior to the entry into the automobile field. Not only were these engines good, but they were very high grade, selling for the highest price in their class, which alone speaks volumes for their construction. Bringing all this experience and the factory which goes with it, to bear upon the construction of a couple of models of automobiles, it will be strange if the latter are not far above the ordinary. Their past performances, of which the Glidden tour was but a single instance, shows that this has come true.

The motor is of 4-inch diameter and a slightly longer stroke, 4 1-2 inches. The arrangement is of the timetried Renault motor, valves all on one side. These latter are made with a 35 per cent nickel steel head, this material being used to avoid the pitting action of the heated gases, experience having proven that this was the only metal which successfully resists that action. The valves and push rods are both adjustable for wear, the adjustments being very accessible. In fact, the company makes a great point of the accessibility of all adjustments, holding the very sensible position that an adjustment which is inaccessible is about as good as no adjustment at all.

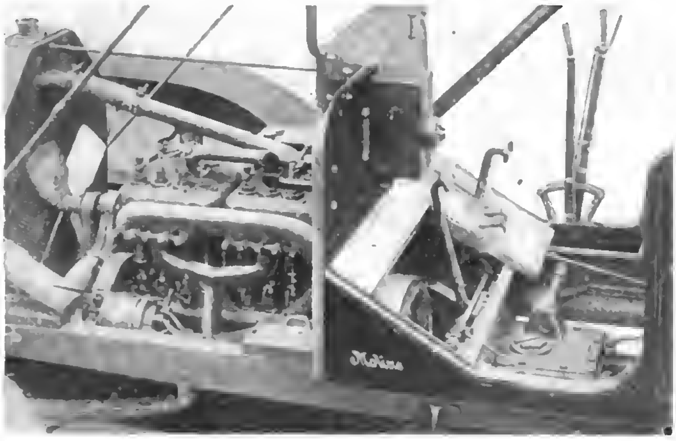
Engine bearings are a nickel alloy metal, made for this purpose. These bearings are long and of large diameter. The crankshaft is a drop forging of selected metal, properly heat treated to bring out the highest strength in the material. Lubrication of the crankshaft bearings and the interior of the case is by force feed, with an oiler located on the engine, from which a sight feed tester is conveniently placed on the dashboard. This brings it right before the driver, so that he can control all lubrication wtihout leaving the seat of the car. For this system, the Moline people claim that it is economical and cleanly, which can not be said of the indiscriminate splash system.

Ignition is cared for in a manner out of the ordinary, for not only is there a magneto system for regular running, and an alternate battery system for starting and emergency uses, but provision is also made for the fitting of a third system, should it become either desirable or necessary. The battery starting arrangement is made complete and up-to-date by the use of a push button placed on the steering wheel. In this way, the motor may be started from the seat. The makers do not specify what magneto is used but say that the best American-made magneto will be used.

Leather-Faced Cone Clutch Is Readily Accessible—The design of the clutch is such that it can be removed from the car, without disturbing anything else, or interfering with the alignment of the motor or transmission, by simply raising the floor boards. It is of the cone type, leather faced with cork inserts, and has ball bearings to take up all thrust. The working parts are completely housed and are packed in grease, which reduces wear to a minimum.

Back of the clutch, that is, in a mid-position, is the transmission. This is of the vertical type that is, the jack shaft is placed below the main shaft, the two being in line in a vertical plane. It affords three speeds and a reverse, operating on the selective plan. On high speed, the drive is direct, no double reduction being interposed to eat up power. Frictional losses are reduced to a minimum by the use of Timken roller bearings, which are used freely, every shaft being mounted upon them. The gears are made from the highest grade of nickel alloy steel, which is hardened and ground after machining to size. The gears are very accurately cut, a close inspection preventing any but perfect ones passing through and thus, entering into the makeup of the car. The aluminum gear box is provided with a large top plate, which is readily removable. This makes it an easy matter to get at any of the gears or shafts for inspection or repairs. The placing longitudinally of the car is also very good, being directly under the footboard where the driver may lift a board, open up for inspection, and go on his way, without leaving the seat.

Both axles show careful designing, the rear being of high carbon steel, which is connected to the power plant at the front by means of the propeller shaft, which contains within its length but one universal joint. The driving shaft is housed in large



Engine and Control Mechanism from the Left Side

diameter tubing, which tapers up to a still larger diameter at the rear end where the greatest strains are likely to come on it. It turns on roller bearings, with a double New Departure bearing at the rear end, just ahead of the beveled pinion to take the thrust there. In addition a torque rod is used to take the reaction of the driving effort back to the frame at a point where it possesses great stiffness. The front axle is of the I-section now in general use, practice having proved this to be the best section for all around strength and stiffness. It is carefully heat treated from a drop forging. The steering knuckles are carried on heavy knuckle bolts, which turn in bronze bushings.

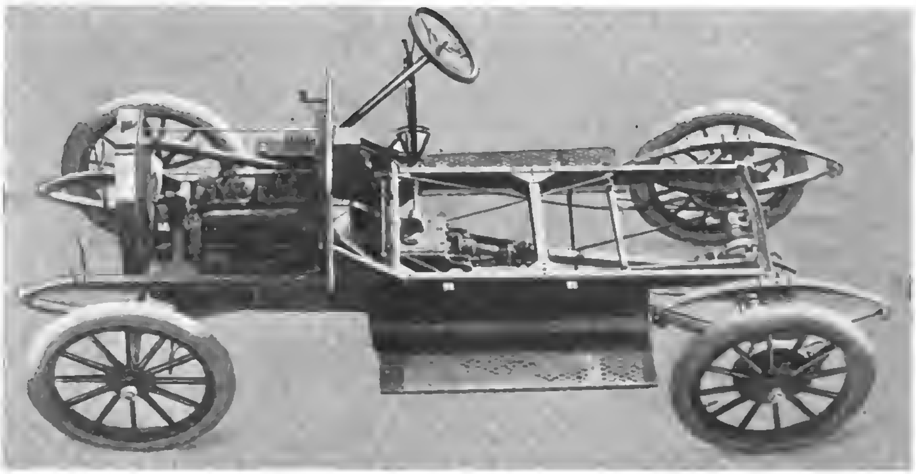
The pressed steel frame is suspended on semi-elliptic flat front springs of rather short length, stiffer springs here giving the best results. In the rear, however, scroll-ended full elliptics, 42 inches long, are used. These are suspended from above the frame so as to keep the center of gravity low. The frame at the rear is slightly upswept, while the rear cross-stiffener is arched over the differential housing, to insure clearance at all times, even with the springs compressed. The frame itself is of channel section, with the open side turned in. All cross members are of the same section, and are united to the main frame by hot-riveting, which makes them a permanent part.

All brakes are placed on the rear wheels, these consisting of one pair of external band brakes, 12-inch diameter, which are controlled by the driver through a foot pedal. The other brakes are internal expanding, and operate by means of a hand lever. The latter is interconnected with the clutch, so that its application also throws this out, and thus cuts off the application of power to the road wheels. The control is located on top of the steering post, and consists of a pair of finger levers, one for the spark and the other for the throttle. For governing the speed of the car a foot throttle is also provided. This is located on the footboard, to the left of the larger control pedals, in a position to be readily accessible to the left foot. Beyond that, in turn, is located the muffler cutout, this small foot pedal opening the muffler, so that the exhaust noise may be used as a signal to teams or other occupants of the road that an automobile is coming behind them. This form of a signal is very convenient. The gear-shifting lever is so arranged as to shift into neutral from certain speeds without a sideways movement. This in particular is useful on the high and second speeds, which are the ones most used. Simplicity of control thus obtains.

Rear Construction Displaying the Scroll Ended Springs

Low speed is obtained in the usual way—by shifting the lever sideways. The steering gear is of the worm and sector type, which is irreversible. A large diameter hand wheel makes the control of the car very easy, and gives the operator full grasp of the situation even when using but one hand to steer with.

Accessibility a Strong Feature—One of the strong points of the Moline is accessibility to operating and mechanical parts. Everything that needs attention can be readily reached and is in plain view by simply removing floor boards and hood which uncover the entire power plant, back to the universal joint, giving ample room for operator to work and make any needed adjustment or repairs for ordinary running. Adjustment of valves is very easy, as exhaust manifold does not interfere. The same is true of the magneto and carbureter. Clutch is also readily accessible. Brake adjustments are made outside of brake drums. The control of the Moline, the care, the ease of operation, and the simplicity of the entire mechanism have made it a favorite with the man who prefers to operate and care for his own machine.



Moline Model M Chassis, Showing to Advantage the Pressed Steel Frame

Cooling is effected by the natural circulation of the water, or thermo-syphon system, as it is called. The radiator is very large, giving a liberal cooling surface, which produces the lowest temperature advisable to use with a gasoline engine.

At the selling price of $1,500 the equipment includes a magneto, two gas lamps and generator for the same, two side lamps, rear or tail lamp, horn, tool box, and a complete set of tools. The latter is unusually complete since this car is intended primarily for the man who takes care of his own machine and patronizes the public garage and repair shop only when absolutely necessary. It was with the idea of proving the adaptability of the car to this class of people that the entries were made in the Glidden tour. It will be remembered by those who followed the course of the tour that these cars carried no repair parts whatever, being the only ones to undertake the long grind without extra equipment. Their success was, therefore, all the more commendable for this reason.

MINERAL GREASES VS. ANIMAL GREASES

Editor THE AUTOMOBILE:

In your valued journal of the issue of August 19 there is published an article entitled "Grease or Oil in Transmission Gears," by H. L. Towle, that contains certain conclusions to which we take serious exception. We refer especially to the last paragraph of Mr. Towle's article, in which it is stated that

"Grease compounded of animal fats have not been considered at all, since while they have their uses, they are distinctly unsuitable for gear lubrication, because of the fact that they remain hard until softened by heat—which heat must generally be engendered by the friction of the rubbing parts themselves. In addition, animal greases are not permanent. They turn rancid in time and form acids very deleterious to bearing surfaces. Where ball or roller bearings are used, grease containing any percentage of animal fats should be absolutely excluded."

Since Mr. Towle has given to mineral greases all of the virtues which properly belong to animal greases, and has, by the same token, condemned animal greases by attributing to them all of the numerous disadvantages possessed by mineral greases for lubricating purposes, it seems opportune to request the use of your editorial columns for the purpose of giving to your readers some definite facts covering the elements which enter into the two products. A brief symposium of the constituents of mineral and animal greases will therefore be given:

Mineral Greases—Under the name may be included various consistent products which are manufactured from mineral oil, horse fat, rosin, and slaked lime, and may also contain solid lubricants such as graphite, talc, etc., or mere filling materials such as barytes and chalk. These greases are poor lubricants.

Animal Greases—Under this name are included all tallow compounds, the yellow lubricating grease so extensively used for bearings of all machinery and transmissions. The main component in this compound being tallow having the highest titre and made from selected kidney beef fats, which, when perfectly compounded and thoroughly boiled to a uniform consistency, have a quality which is superior to the best mineral compounds.

A transmission will contain within itself both quick and slow speeds and heavy and light pressures; now, it will follow, that to efficiently lubricate these gears a lubricant is required that is free from impurities, always uniform in quality, and suited to all conditions, having a comparatively low melting point, so that it will readily melt between the teeth of the gears. Thus the bearing surface will be in the state of an oil-lubricated bearing. Since the friction cannot be reduced till the temperature of the bearing or bearing surfaces of the teeth has risen enough for the grease to melt, or at least to be softened so it can flow over them, it follows that other things being equal, the grease with the highest melting paint (mineral greases) will produce the highest coefficient of friction. Hence the lowest melting grease that will stay in the bearing surface will have the lowest coefficient of friction, which is only another way of saying that a grease melting—i.e., an emulsion—will give the best results wherever it can possibly be used.

It has been noted in all tests that the lime soap greases (mineral greases), the most common type to-day, do not give as good results as the oldest, though more expensive type of tallow greases. These facts have been many times demonstrated in efficiency tests, therefore mineral greases are looked upon as a very undesirable class and if kept for any length of time they oxidize and become rancid, indicated by their rapid discoloration when exposed to the air, having a great affinity for oxygen, which they readily absorb, though cheap of themselves and in reality most expensive, being inefficient and destructive.

On the other hand, a good boiled tallow grease is perfectly neutral, and will remain so for an indefinite length of time. In consistency it can be made anywhere from a soft plastic state (through which the gears do not cut a path, as the mechanical action or agitation produces an emulsion that continually feeds and clings to the surface of the gears, lubricating the points of contact thoroughly) to one of a very tough and hard body (where pressure from a compression cup acts as the feeding force) and thereby adapt themselves to any condition whether used in a transmission case or on the most critical bearing of a motor or machine.

A perfect lubricant exemplified by a high grade tallow grease will virtually eliminate the drip and waste and muss of fluid oil and the clogging, dragging effect of mineral greases, consequently absorbs less power in the transmissions, at the same time protecting the gears by cushioning the shocks of changing speed, being a lubricant which will distribute readily and not leak from the casings.

New York City. ADAM COOK'S SONS.

MARMONS MAY OR MAY NOT RACE

Editor THE AUTOMOBILE:

It has been reported in trade papers that we will never again participate in track or road races. We have never made a statement of this kind. We are not saying that we will take part in race events, and we are not saying that we will not take part.

Indianapolis. NORDYKE & MARMON COMPANY.

DETAILS OF THE SANTA MONICA RACE

Editor THE AUTOMOBILE:

Perhaps your readers would like some further information regarding the Santa Monica road race. This is the fastest stock-car race ever run in America, the winner averaging 64.45 miles an hour. One race was faster—the Savannah—by a fraction of a mile. It was faster than any Vanderbilt and far superior to the Cobe trophy, with its miserable 49.26 miles an hour.

The course is 8.4 miles in length and the total distance covered 202.4 miles. It is situated between Santa Monica and Los Angeles, running along the ocean front and through the town of Santa Monica. The drivers agreed to a man that it was the best managed as well as the speediest course in the United States.

The winning average of the Chalmers-Detroit, driven by Bert Dingley, in the light car race was 55.5 miles an hour. This is the fastest of the small car races. Dingley was given a close run for the money by Siefert, another excellent driver who piloted his Stoddard to a good second. The Buick driven by Nikrent took third.

The "Big Race" started at 8 a. m. before a crowd of 40,000 people. The Apperson won in splendid time after a well-driven race. The Chadwick with Seibel as driver took second, Stearns third and Locomobile fourth. The winning cars did not have to replace a single tire, and only two or three spares were used during the whole day. This is a plain testimonial of the quality of the course.

The fact that only a slight mention of this race was made in your magazine, although pages were given to describing the much inferior Cobe and Indiana races, moved me to give you a little more specifically the details. INVISABLE GREEN, JR.

Pasadena, Cal.

The Santa Monica race was undoubtedly fast and interesting, and our notice perhaps inadequate, but in judging its value relative to the Eastern races there are several points our correspondent has failed to take into consideration. Principal of these is the distance. The Santa Monica race called for 202.4 miles; but the last Vanderbilt was 258.1 miles, the Cobe trophy 395.6 miles, and the Savannah race 402.1 miles. No car or driver can be expected to make as good time in a 400-mile race as in one of 200 miles. But, for that matter, speed is not the only desirable quality in road racing. One of the purposes of this form of contest just as important as finding a car's greatest speed is to test its endurance. Entirely aside from quality of the racing, the Santa Monica race was little more than a local affair, whereas the other races were national in their scope.

BOSTON'S HARD-USED AUTOMOBILES

BOSTON, Sept. 20—Mayor Hibbard recently sent to the board of aldermen a communication concerning the city's automobile equipment. The city has 26 machines, 17 of which have been purchased since Mayor Hibbard took office January 1, 1908. During his administration the city has expended approximately $108,000 on automobiles. For new machines the city has paid $65,533.13, for maintenance and repairs $29,962.51, and for wages of chauffeurs $12,502.89. The police and fire department have six machines apiece, the street department three, the water and bath department two each. The building, engineering, hospital, park, public grounds and schoolhouse departments have machines, and the mayor's office has a car.

Automobiles in the service of the city apparently receive hard usage, or else the city is not sharp at trading, for machines that have been sold have brought poor prices. Three runabouts for the police department that cost $2,038 sold for only $50, a car costing $1,003.50 brought $126, another that cost $1,350 sold for $176.40, and a runabout costing $708.15 sold for $175. The mayor's car has cost $7,877.46, of which $3,360 is for the car, $3,276.76 for maintenance, and $1,240.70 for the chauffeur.

OHIO TOWNS TO HOLD ANNUAL HILL-CLIMB

UHRICHSVILLE, O., Sept. 20—The Twin City Automobile Club, of this city and Dennison, O., has decided to hold its second annual hill-climbing contest Friday, October 1. The cars are to be divided in five classes, for roadsters under and over 24 horsepower, for touring cars under and over the same limit, and for single-cylinder cars. The winner in each class will receive a silver cup. A parade of decorated cars will be held in the forenoon, for which additional prizes are offered.

THE PROBLEM OF THE ROADS

The problem of the roads really concerns everybody, including the man who may think himself exempt for the reason that he does not drive or ride in a vehicle which travels over the highway. But even he cannot escape the effects of bad roads, with the attending greater expense to the farmer, who supplies him with the necessities of life, and who consequently must exact a greater toll for the delivery of his farm products.

Another thing which is as certain as the rising of the sun on the morrow, is that all road users will employ motor-driven vehicles in the not distant future—a future which has been greatly lessened in prospect in the last year or two, with the arrival of the moderate-priced car and its assured sturdiness and reliability.

While it would appear that the National Good Roads Convention in Cleveland this week has an automobile aspect, and the participation of the National Grange is only illustrative of the growing friendliness between the man who contributes substantially to the building of the highways and the man who uses them most assiduously, the man of the country is in reality actuated by personal interest rather than by a desire to serve in the capacity of a partial philanthropist.

This is a great country, of vast distances, and the building of its roads is a work that will have to continue for many years; but judging from the present widespread interest from coast to coast, it will soon be possible for tourists to ride in comfort through any commonwealth which pretends to keep abreast of the times.

When that time comes and our own roads are the equal if not the superior of the famous roads abroad, it will be possible for the man of moderate means to see the country as he never saw it before. If from no other point of view than a selfish interest in future possibilities, this movement should thus have universal support.

ECONOMIC VALUE OF ROADS

Every inhabitant of this country is vitally concerned in its roads. Whether a man uses the roads himself, in a carriage or automobile, has little bearing on the matter; if he does, their faults are brought home to him by his bodily discomfort. If he does not use them, he may stay at home comfortably in an easy chair, but he pays tribute to them equally with the user.

Transportation is civilization; and transportation by road is no less important than transportation by rail or by water. Every article of food or clothing, every daily necessity or luxury, must be carried to the person who is to use it, and the user must pay the expense of carriage. The price of each loaf of bread includes the cost of hauling the wheat to the railroad; and if the hauling is done over bad roads it will cost more than if it is done over good roads. The farmer of the Middle West loads a dozen hogs into his big wagon and drives over to the railroad; if the drive is over rough roads the hogs lose weight, and the New Yorker, sitting down to breakfast a week later, pays more for his pork chops.

The general public has just begun to realize the immense importance of railway transportation in its daily expense accounts. Therefore the Interstate Commerce Commission was delegated to see that this transportation was done as cheaply and efficiently as possible. The Federal Government yearly appropriates millions of dollars for the improvement of waterways, that this form of transportation also may be as cheap and efficient as possible. Yet the roads, which are at least as important as either the rivers or the railways, remain in almost the condition of a hundred years ago.

The cost of road haulage in any one article is almost infinitesimally small, which may lead the casual observer to think that it may be neglected. Railroad rates may be quoted at so many cents a ton, but the cost of a ton-mile in a farmer's "jolt wagon" is not so easy to figure out. Yet those infinitesimal fractions are always present, and it has been estimated that in the course of a year they add up to $250,000,000.

LAUDABLE SALES CONVENTIONS

A practice which is growing rapidly, all over the country, is that of calling all of the salesmen, both travelling and local representatives, together for a long and very thorough discussion of the new models, and in particular the changes about to be advanced. This is one that is worthy of commendation. It results in the widest possible discussion both pro and con, of the newer features, which cannot help but be a benefit to the purchaser in the long run. Put in another way, this discussion represents the voicing by the man who sells, of the wants of the man who buys, that is, the ultimate consumer.

MANY CHICAGO AMATEURS IN RELIABILITY RUN

CHICAGO, Sept. 19—Tables were turned by the Chicago Automobile Club on its friendly rival, the Chicago Athletic Association, last Thursday when the two organizations met in their second annual inter-club reliability team match. Captain N. H. Van Sicklen's clever pilots captured the honors, which in this case meant the huge shield which is up for perpetual competition between the two clubs. Another bit of plunder that fell to the lot of the Automobile Club men was a cup put up by F. H. Rawson, treasurer of the C. A. A., to become the permanent possession of the winning club, which in this instance was the C. A. C. There wasn't much difference between the two teams, a matter of only 23.46 points, and in a way the Cherry Circle had it on its conqueror in that it returned eleven perfect scores out of a possible thirteen, while the winning team had three down out of ten. The gross score was 180 points for the C. A. A. and 115 for the C. A. C. The loser's total was decreased, though, by the fractional penalization made necessary by the uneven sides—thirteen on one team and ten on the other.

The run, though, demonstrated that the amateurs are really better drivers than they thought, for of the twenty-three that made the 150-mile journey Thursday eighteen of them went through without mechanical trouble or being late at controls. The 18-mile an hour schedule was easy to maintain, and only two penalizations were for being late at controls. Those who got into trouble were Frank X. Mudd, T. J. Hyman and F. R. Robbins, of the Chicago Automobile Club team, and R. T. Laughlin and Charles T. Knisely, of the C. A. A. Mudd started out with a leaky radiator, which bothered him all the way, and, coupled with tire trouble made him late in getting home. Hyman was penalized for two motor stops, and Robbins was demerited for being late in checking in at the noon control, caused by stopping at Crown Point for gasoline and imagining the time he took for this would be deducted from his schedule.

On the other side of the fence, Laughlin drew the biggest penalty, brought about for work done on his car at Cedar Lake, and Captain Knisely was penalized for motor stops. Otherwise the Cherry Circle forces were in good order and went through the test like veterans.

The conditions of the match were not as strenuous as prevail in some of the reliability runs. Being open only to owners who were in no way affiliated with the motor trade, there was no demand for a technical examination of the cars, the run being more in the nature of a test of driving ability than of the cars. Therefore the demerits were handed out for motor stops, for repairs, adjustments or replacements and for being late at controls. These were just enough to make the match a sporting proposition and close, in that the chances of many being penalized were slight.

As laid out, the course took in 150 miles, mostly in Indiana, the route running into the Hoosier state through the old channels and making Cedar Lake the noon control. Cedar Lake is on the western leg of the Cobe cup circuit, and naturally that historic course was an object of interest, so it was included in the route. From the noon stop the contestants bore away from Crown Point to Valparaiso and from there came in through Hobart and Highlands. The roads were in splendid condition except for the entrance into Chicago, which was as usual in poor shape. The report of the judges was as follows:

CHICAGO AUTOMOBILE CLUB.

Car No.	Driver	Car	Score
1	N. H. Van Sicklen	Apperson	Perfect
3	Frank X. Mudd	Ford	60 points
5	Walter Egermann	Rambler	Perfect
9	Carroll Shaffer	Stevens-Duryea	Perfect
11	B. B. Ayers	Cadillac	Perfect
15	T. J. Hyman	Chalmers-Detroit	50 points
17	R. O. Evans	Apperson	Perfect
19	Godfrey Baackes	Peerless	Perfect
21	Sidney S. Gorham	Jewel	Perfect
23	F. R. Robbins	Stoddard-Dayton	5 points

CHICAGO ATHLETIC ASSOCIATION.

Car No.	Driver	Car	Score
2	C. T. Knisely	Palmer & Singer	35 points
4	S. W. Hamm	Locomobile	Perfect
6	R. T. Laughlin	White	145 points
8	W. C. Thorne	Palmer & Singer	Perfect
10	H. N. Scott	Locomobile	Perfect
12	H. C. Knisely	Premier	Perfect
14	G. F. Griffin	Peerless	Perfect
16	E. E. Vail	Stoddard-Dayton	Perfect
18	Albert Coon	Stoddard-Dayton	Perfect
20	F. W. Wentworth	Rambler	Perfect
22	Eugene Benzat	Stoddard-Dayton	Perfect
24	W. E. Davis	Mitchell	Perfect
34	C. C. Ireland	Stoddard-Dayton	Perfect

ROBERTSON AGAIN IN FAIRMOUNT

PHILADELPHIA, Sept. 20—Robertson, last year's winner of the Fairmount Park 200-mile stock chassis race, will try for the honors at the second running of that fixture, Saturday, October 9. It is not yet known just what entry he will drive, but in all probability it will be the Bergdoll Simplex. Other shining lights who will be at the wheels of the various flyers are Len Zengle, the ex-Chadwick crack, who, although now with his first love, the Pennsylvania, will drive the Chadwick entry; Willie Haupt, also an ex-Chadwickite, who will guide one of the Bergdoll Thomases; "Bill" Wallace, who hopes to land his Palmer-Singer in front, and Herbert Lytle, who is banking on his Apperson Jack Rabbit. Mulford will in all likelihood drive the Lozier entry. As two Chalmers-Detroit entries have been promised, Lorimer and Dingley are also likely to be in the line-up.

SIMPLEX VICTORY AT LOWELL SUSTAINED

LOWELL, MASS., Sept. 20—The awards as first given out in the National Stock Trophy race at Lowell were sustained by the Contest Board of the A. A. A. The Simplex, which finished first, was protested by two other contestants on the ground that it carried a special chain-oiling device. The technical committee made an investigation in the Simplex factory and discovered that the device in question will be, as was claimed at the time, a part of the Simplex stock equipment in 1910.

BRICK FACE FOR INDIANAPOLIS TRACK

INDIANAPOLIS, Sept. 20—After deliberating over the question since the recent speedway races, which ended so disastrously, the management of the Indianapolis Motor Speedway has decided to resurface the course with brick. This decision is the result of tests made on the track. The brick is expected to give a fast and durable surface and to provide a good hold for the tires in any kind of weather.

A shed for housing airships during the aviation meet next month is nearing completion. This building will be 300 feet long and 60 feet wide, and will accommodate two dirigible balloons, fully inflated, or several aeroplanes.

PACKARD WINS RACE TO EL PASO, TEX.

EL PASO, TEX., Sept. 17—C. A. Root and W. M. Jones arrived here this morning in their Packard from New York, having traveled 3,872 miles. They left New York August 22, in company with a Mitchell and Cleveland. The former dropped out in Chicago, and the latter has not been heard from for several days.

DE PALMA MAKES ANOTHER TRACK RECORD

GRAND RAPIDS, MICH., Sept. 18—At the State fair yesterday De Palma and the Fiat *Cyclone* broke the track record for 25 miles. His time was 22:59 3-5. The previous record, also held by De Palma, was 23:35.

THE STRUGGLE FOR RAW MATERIAL AND SPACE

DETROIT, Sept. 20—Preparations being made to build automobiles are on so vast a scale that the market for raw material is rapidly being depleted. Besides the many new companies that are forming, some of which are so well advanced that they have models on the road, the established concerns of magnitude are enlarging their plants, in numerous cases more than doubling the output.

In the meantime producers of raw material were not prepared for so vast a business, and would have been pressed in furnishing barely the amount of material used in 1909, for the cars that were but recently finished. Under the circumstances, the vast increase in the number of automobiles being built, has resulted in a famine of raw material, and parts makers are all working up to the limit, with plant increases going on, governed, not by the amount of business they can command, but by the amount of raw material they are able to definitely contract for.

Glancing over the situation in general, without attempting to cover the ground in anything like a thorough manner, leads to the conclusion that the makers of cars are preparing to do their own work in so far as it is possible to do so, and many of the parts establishments are tied up by contracts which practically mean that they have been annexed to makers of automobiles on a large scale.

In Buffalo, for illustration, the Pierce-Arrow Motor Car Company is adding to its splendid concrete buildings, to an extent which will probably allow of doubling the output. The E. R. Thomas Motor Company is making additions to buildings such as will almost completely draft the remaining available ground, and this work is so far advanced that the Thomas output will be easily double what it was for the last year. The Sterling Engine Company is just finishing up its last season's work, having done more marine work than ever before, and plans are maturing for a large addition to the plant, which includes a wing to the back of the main building almost, if not quite, equal in floor space to the present plant.

Cleveland Shops Are Overcrowded—What is true at Buffalo is simply duplicated at Cleveland, and one of the best indications of the rate at which cars are being built, will be found in the numerous parts shops located there. The Perfection Spring Company, for instance, added on to its plant on a basis of 200 per cent, and with this condition barely established, the company is confronted by the need of more room. In plants like the Winton Motor Carriage Company, the situation is a little less congested, due, perhaps, to specializing on a class of relatively high-priced cars, and to years of experience along this line, thus rendering it possible to foresee wants.

Great Activity Centered at Detroit—McCord Manufacturing Company, with vast resources for turning out such accessories as radiators, force feed lubricators, fans, etc., has near to completion a new building which will enable the company to build at least 50,000 more radiators this year, and, subject to ability to make deliveries, the company is threatened with more than this amount of business in addition to booked orders which will task the entire plant. The new disc fans by the way, which this company is making a specialty of, are in great demand, and they differ from the usual product in that the blades are made in dies, all at one time, and are mounted on a hub construction of pressed steel. This branch of the company's factory is working, like the rest, 23 hours out of every 24.

The Regal Motor Car Company, with 2,000 of Model 30 on the road, as the effort for 1909, is spreading all over the block of ground, where once the Regal occupied but a small space in a single building in the middle of the same block. Work on the Regal evolution, which is the 1910 revise of the 1909 Model 30, is so far advanced that there is assurance of a big increase over the 1909 output, especially since the commodious new building is now housing the car assembly work, and affords space for important detail performances as well. The Regal is one of the companies which is not suffering so much from a famine of material, due to having a foundry of its own, and the Regal car will therefore reflect a certain stability.

At the plant of the Ford Motor Company, foresight is represented by a yard full of chassis frames, motor cases by the half acre, cylinders and other parts to match, rather tending to show that Henry Ford does not intend to participate in a material famine.

At the plant of the E.M.F., the new building is advancing near to completion; it promises to house much additional work, yet, at the same time, the company is building cars all over the yard, as well as under roofs, so that the high pressure system imposed by the management scarcely takes notice of such details as roofs and floors.

The Studebaker-Flanders organization keeps the "wiseacres," in the lobby of the "Pontchartrain," working overtime, "doping" out stories of one kind and another, all of which are rose-tinted and deal in "chunks," when it comes to telling about the number of cars the company will have on the road ere snow melts, and according to them, Studebaker-Flanders methods cannot help but result in more cars this year than were turned out by all the companies combined during 1909.

During 1909, it was variously estimated that the output of all the companies was about 80,000 cars. This year, taking the square root of the mean square of "guesses," 250,000 cars will hit the mark. The average price per car will fall but just a little lower than formerly; not so much so, perhaps, as some may think, even counting 25,000 cars at $750 each, which, according to Mr. Flanders, in his interview of a day or two ago, with the writer, was the figure set by him for the quantity of cars the company would turn out.

To put out this number of cars within a single year, requires much effort at the command of men who know how to do things, and real estate activity in and around Detroit, involving the name of Studebaker-Flanders rather goes to clinch the contention that the attempt is being made.

The Studebaker-Flanders organization is loath to disclose its real estate plans. Mr. Flanders stated to the writer that newspaper statements of late were far from the truth, and, as a matter of fact, it is too early to expect anything from this source.

Brush Runabout Company, with seven new models, is probably making as good a showing as is possible for any organization. Nothing but a well organized establishment could undertake so large a task with the hope of cleaning up the shop orders on time. The trouble is that the Brush runabout is much in demand, its road performance is pronouncedly in favor of a large future, and the company is rapidly eating into all the spare room the Briscoe Manufacturing Company can afford to give up in view of a most extraordinary rush of business in its own line. Briscoe radiators are in greater demand than ever, and the booked orders are simply up to the limit of shop capacity. Briscoe has other plans in a large way.

In the Cadillac plant, everything is so standardized under the able guidance of H. M. Leland that each day's progress is definitely decided upon, at each morning's conference, and the work in the shop goes on almost uneventfully. The Cadillac is one of the companies which operates its own foundry, builds its own radiators and other parts, and is independent of outside ordering.

Anderson Carriage Company is pushing electrics in a surprising way and the big new plant is busy almost to overcrowding. This company, it will be remembered, are the builders of the well-known "Detroit Electric." This company turned out but 78 cars two years ago, while the output for the past season has increased to 525. For the ensuing year, plans now under way, will result in a production which totals 1,000 electrics. The company is now working 465 men and rapidly increasing this force.

FIRST SOUTHERN NATIONAL SHOW PROMISES GREAT SUCCESS

ATLANTA, GA., Sept. 20—Diagrams have been made out showing the arrangement of the exhibitors at the Atlanta National Automobile Show, which will open November 6. Practically every American automobile manufacturer of note and a number of foreign machines are represented. Altogether, there will be about sixty exhibitors of complete cars, and in addition many accessory concerns. The latter, represented by the Motor & Accessory Manufacturers' Association, will receive notice of their allotments of space within a few days. Several late applications were received, among which were those of the Studebaker, E. M. F. and Autocar companies. Now that the assignments of space to these late comers have been made, practically every square foot has been taken.

The Atlanta show will be the first to be held during the winter, and as most of the 1910 models have already been announced, it is probable that they will form the great majority of the exhibits. Thus the Atlantans and their visitors will have the first opportunity to see the various types for the coming year side by side and compare their merits.

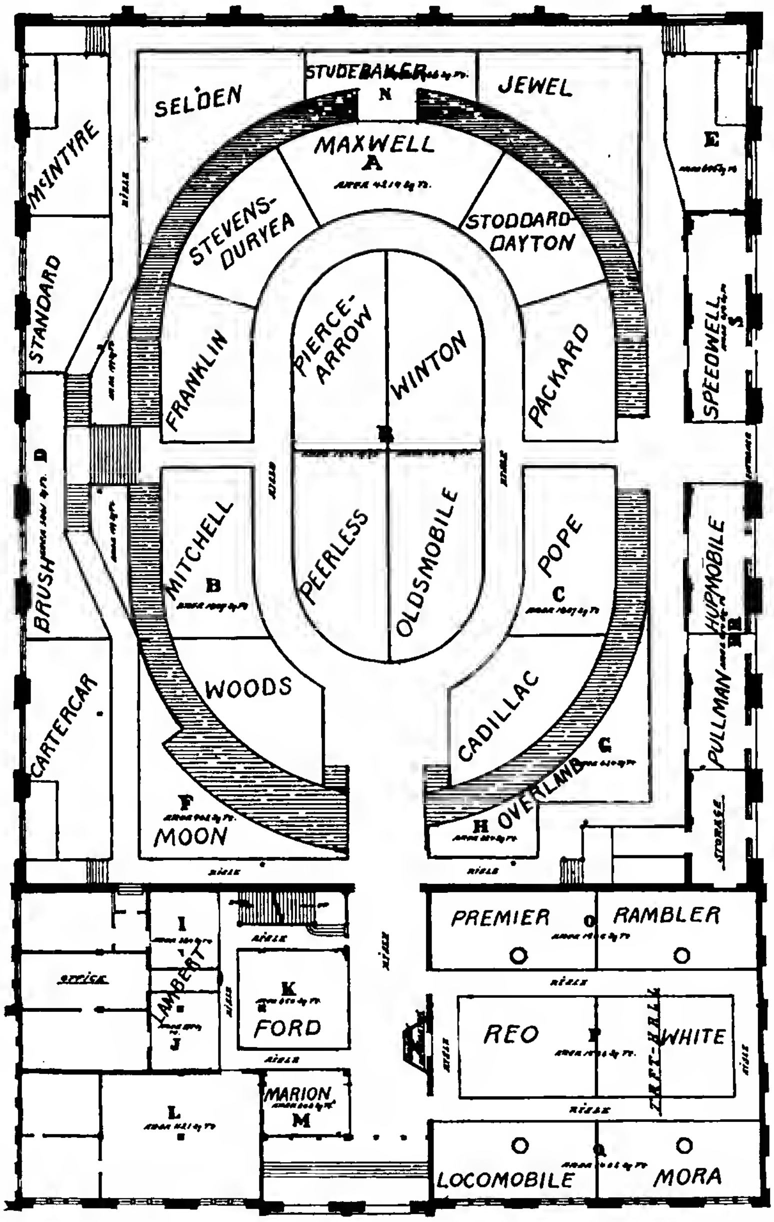
The show will not be the only attraction in Atlanta, however. During the same week will be held the opening meet on the Atlanta Speedway, which the Southerners claim will eclipse that of Indianapolis. In general, the week will be a time of festivity, in which Southern traditions of hospitality will be given full play. Merchants and capitalists of the city have raised a fund of $20,000 for the entertainment of the city's guests, and the whole region of Peachtree street will be put in gala attire.

Among the prominent firms reserving space on the main floor are many that are well known all over the country, all of the larger firms being represented. The publication of the diagrams has been a source of great surprise to those not in close touch with Southern affairs, for so representative a list is seldom seen outside of the New York and Chicago shows. The complete list of main floor exhibitors is:

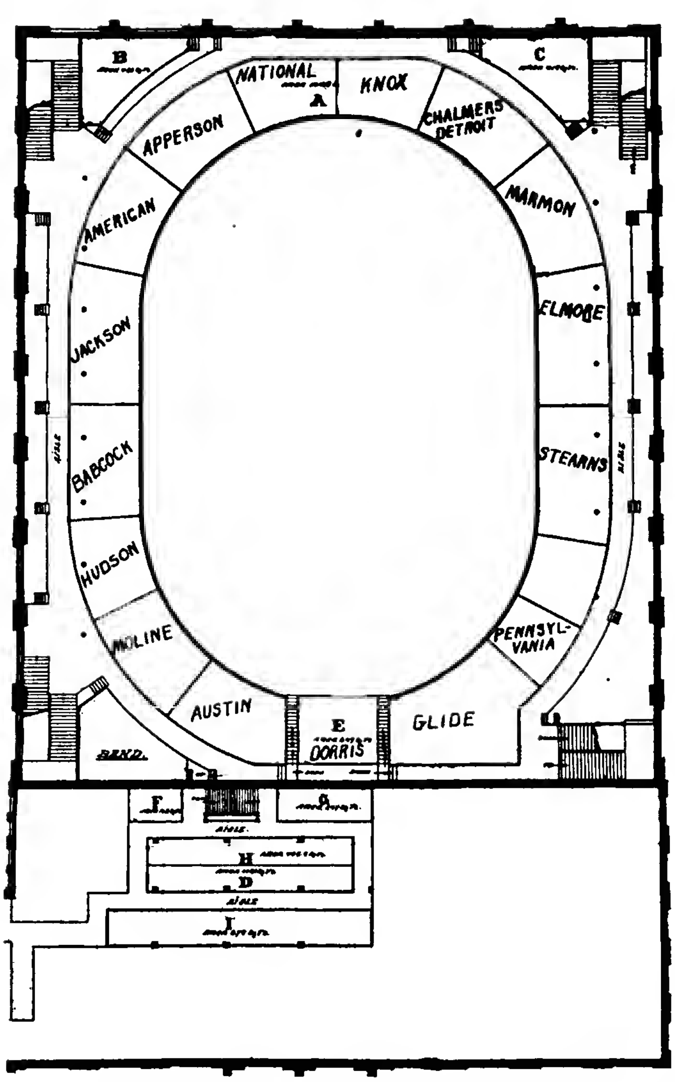
Pierce-Arrow Motor Car Company, Peerless Motor Car Company, Packard Motor Car Company, Winton Motor Carriage Company, Pope Manufacturing Company, H. H. Franklin Manufacturing Company, Stevens-Duryea Company, Cadillac Motor Car Company, Maxwell-Briscoe Motor Company, Dayton Motor Car Company, Mitchell Motor Car Company, White Company, Woods Motor Vehicle Company, Reo Motor Car Company, Locomobile Company of America, Mora Motor Car Company, Premier Motor Manufacturing Company, Thomas B. Jeffery & Co., Ford Motor Company, Marion Motor Car Company, Buckeye Manufacturing Company, Moon Motor Car Company, Overland Automobile Company, Cartercar Company, Brush Runabout Company, St. Louis Car Company, McIntyre Company, Selden Motor Vehicle Company, Croxton-Keeton Company, Studebaker Automobile Company, Speedwell Motor Car Company, York Motor Car Company, Hupp Motor Car Company.

This absolutely fills all of the first floor spaces except two, both of them rather small, and both located in somewhat out of the way places. The rest of the ground floor is taken up with the administrative offices, dressing rooms, storage spaces and other similar but small amounts of floor space which could not possibly be used as exhibition spaces.

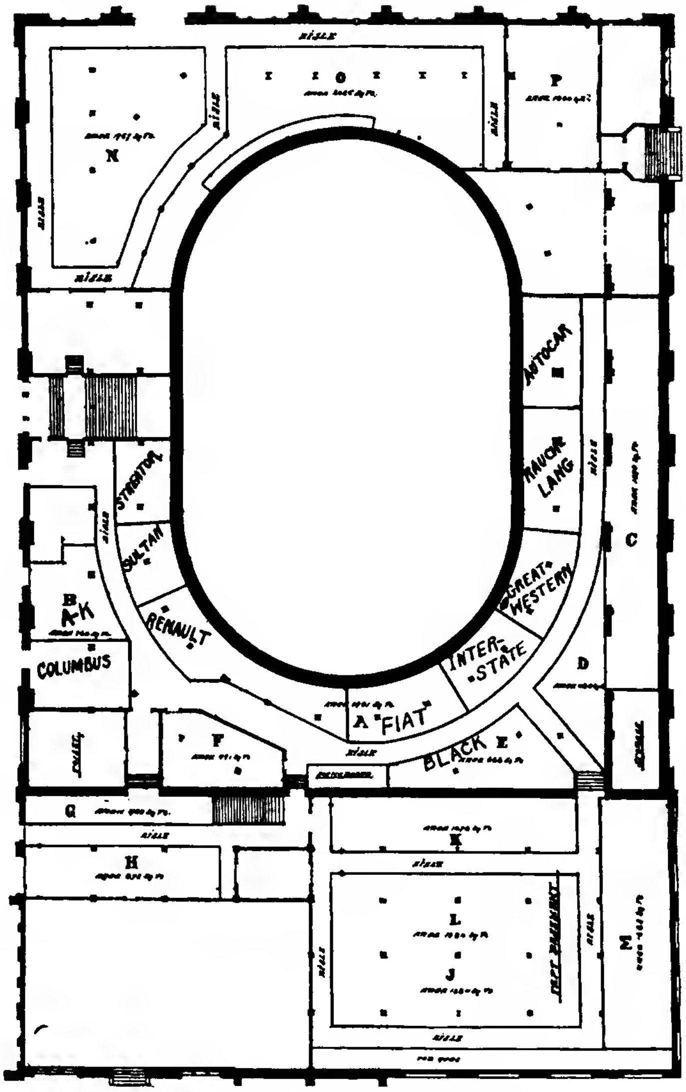
On the mezzanine floor visitors to the show will find the following exhibitors: Austin Automobile Company, American Motor Car Company, Apperson Brothers Automobile Company, Babcock Electric Carriage Company, Chalmers-Detroit Motor Company, Dorris Motor Car Company, Elmore Manufacturing Company, Bartholomew Company, Moline Automobile Company, Hudson Motor Car Company, Pennsylvania Auto Motor Company, F. B. Stearns Company, Nordyke & Marmon Company, Jackson Automobile Company, National Motor Vehicle Company, Knox Automobile Company. This leaves but five bare spots on the whole floor, which will be taken up without a doubt by the late comers. Proceeding to the basement, one finds located there the following firms: Renault Freres Selling Company, Fiat Automobile Company, Inter-State Automobile Company, Great Western Automobile Company, Rauch & Lang Carriage Company, Autocar Company, Streator Motor Car Company, Sultan Motor Company, Black Manufacturing Company, Allen-Kingston Motor Car Company, Columbus Buggy Company. This leaves only fourteen more spaces to be filled up before the curtain goes up on the greatest automobile show ever held in the sunny South. A number of manufacturers who failed to realize the National, as well as sectional, importance of the show in time for the first allotment will doubtless snap up these spaces long before the opening date.



Plan of Main Floor of the Atlanta Automobile Show



Arrangement of Mezzanine Floor, Atlanta Show



Plan of Basement, Showing Various Subdivisions

APPLY SOON FOR A. M. C. M. A. SHOW

The American Motor Car Manufacturers' Association calls attention to the fact that applications for space in the New York show, which opens in the Grand Central Palace on New Year's Eve, must be received before October 1 in order to participate in the first allotment. Last year a number of concerns were unable to secure any space at all, owing to their failure to file their applications within the appointed time, and the show committee of the A. M. C. M. A. desires this year to be free from such disappointments. In past years the first allotment has disposed of the entire 72,000 square feet of space in the Palace.

MARCH DATE SET FOR BOSTON SHOW

Boston, Sept. 21—At a meeting held recently, it was decided to hold the Boston show, this being the eighth annual for the Hub classic, in Mechanics Building on March 5 to 12, 1910. Indications now point to the greatest show ever held, while the management is planning a decorative scheme which will be equally as much of a record breaker. Manager Chester I. Campbell and an able corps of assistants claim to have planned decorations described only by such language as "the most elaborate yet, and of a grandeur never before attempted." The floor diagrams and other printed matter are now in the hands of the printer.

DEATH ENDS TRANSCONTINENTAL

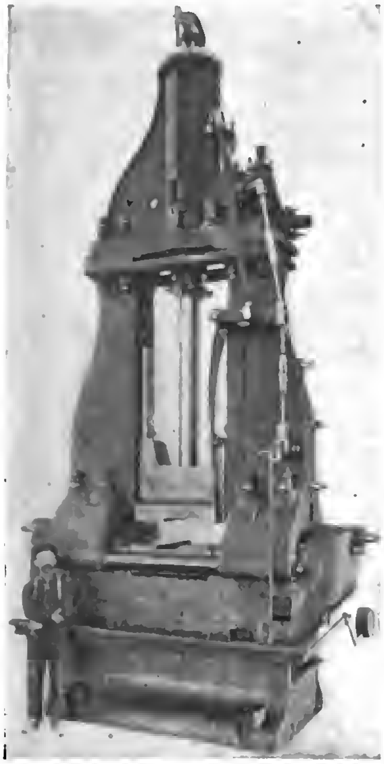
Philadelphia, Sept. 20—The transcontinental relay trip promoted by the *Press* of this city, and which started promptly at 12:30 P. M., Saturday from City Hall, came to an abrupt termination before the completion of the first relay, when the Acme, driven by Clifford R. Ely, which was to cover the first leg of the journey, met with an accident at Robesonia, ten miles beyond Reading. Henry L. Buckley, automobile editor of the *Press*, one of the two messengers, sustained a fractured skull, dying two hours later at the Reading hospital; William H. Brown, a guest of Driver Ely, is in a serious condition at the same hospital. Ely, his assistant, and another passenger, suffered slight cuts and bruises. The car was wrecked. The *Press* authorities immediately wired all along the route, calling the relay off. The cause of the accident has not yet been ascertained.

2,456 GUESSES ON PREMIER RUN

Philadelphia, Sept. 20—Owing to the fact that no less than 2,456 residents of towns along the route of the recent Premier reliability run from this city to Cape May had sent in guesses as to the number of the winning car and the time in which the 96 miles would be covered, it was impossible to announce the official figures until Wednesday. B. E. Block, of Norristown, the winner of the cup, drove his car over the course in 4:57:45, just sixteen seconds slower than the official time. But one of the guessers selected Mr. Block's car, number 29, and that was James Martin, of Waterford, who took down the biggest bit of cash hung up by the promoters. Elizabeth McCarthy, of Germantown, whose guess was but an even ten seconds shy of the official time, captured second money. Twenty prizes in all were thus distributed.

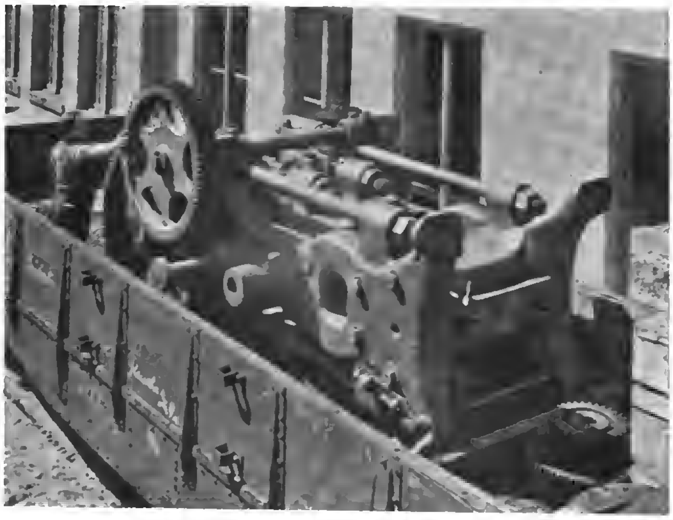
NEW RAMBLER FACTORY AND MACHINERY

KENOSHA, WIS., Sept. 20—The Thomas B. Jeffery Company has made extensive additions to its plant recently, which, when completed, will entirely change its appearance. The new buildings, owing to the abundance of land at the company's disposal, have been made only one story in height, and will give the workmen all the light and air that could be desired. They are of reinforced concrete, with saw-tooth roofs made up almost completely of glass. Some idea of the extent of these buildings may be gained from the photograph.



Rambler Steam Forging Hammer

Two of the machines to be installed in this addition to the plant are also shown in the illustrations. This new machinery is expected to facilitate and cheapen the manufacturing processes to an unusual degree. The steam drop-forging hammer, to be used in the making of crankshafts, connecting rods, front axle yokes, and other heavy forgings, weighs complete 49 tons. The hammer itself weighs 3,500 pounds, and the anvil block 35 tons. The machine will be installed on a foundation of solid concrete sixteen feet deep and fifteen feet square. Another machine which comes in the same heavy-weight class, and which in modern manufacturing methods is equally important, is the 500-ton drawing press, for making brake drums, clutch cones and other parts of drawn steel. This press weighs complete 30 tons. Such equipment follows the policy of spending money to save money.



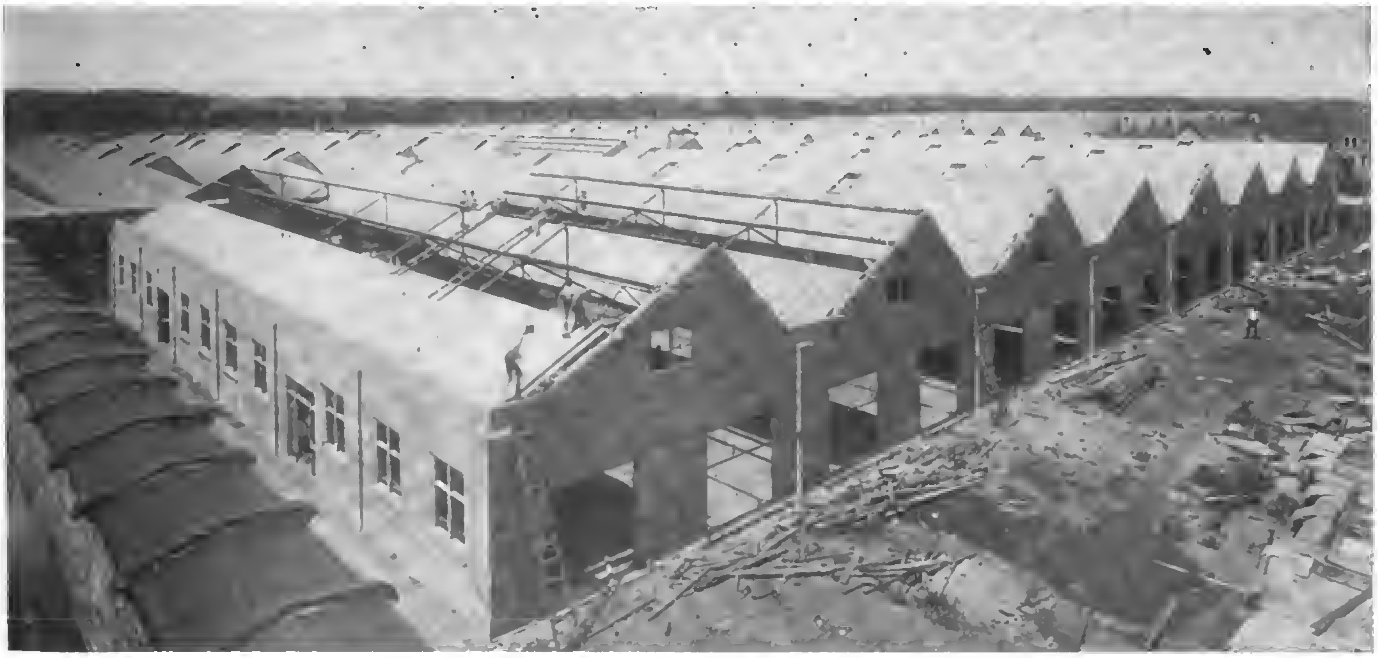
Drawing Press in Car Alongside New Rambler Factory

ENGINEERING EXHIBIT OF FULTON RELICS

The Hudson-Fulton celebration is essentially a recognition of the engineer and the explorer. To show the progress of engineering science, models of the Clermont and other early steamboats, through the courtesy of the Smithsonian Institution, are now on exhibition at the rooms of the American Society of Mechanical Engineers, 29 West Thirty-ninth Street, New York. The exhibit includes the Clermont, the Phoenix, built by John Stevens, and one of John Fitch's early types. By way of contrast, the Hamburg-American line has loaned the exhibit a beautiful model of the *Deutschland*, showing one of the highest developments of steam navigation. The exhibit will be open to the public every week-day from 9 a. m. to 5 p. m.

SELLING BRANCH FOR SPARE WHEELS

ST. ANNE, ILL., Sept. 20—The Spare Motor Wheel Company, of this city, maker of Stepney spare wheels, has disposed of its entire output for the coming season to the American Stepney Spare Wheel Company, of 1773 Broadway, New York, who will in the future have entire charge of the disposition of this product. The St. Anne company has enlarged its plant and equipment, and is manufacturing clincher and other rims besides spare wheels.



Addition to Rambler Factory: This Wing for Accommodation of Laboratory and Motor Testing and Repair Departments

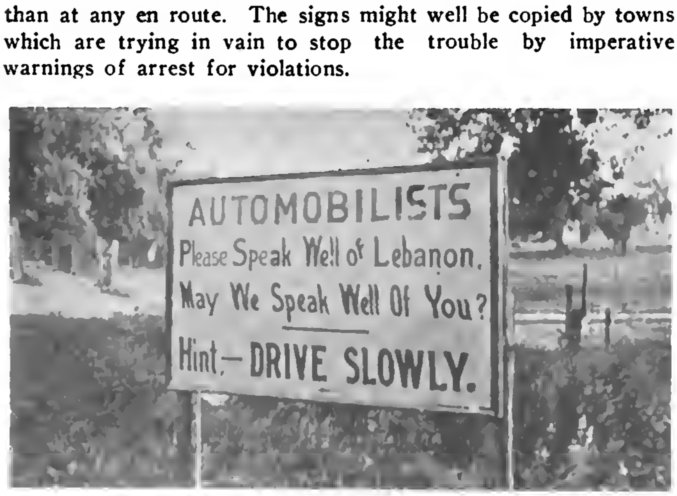
Hoblitt in Alco Asks His Way of an Ohio Farmer

A BUSINESS TOUR OF 5,000 MILES

Five thousand miles was the sum total of a business tour recently completed by F. M. Hoblitt, the pioneer automobile salesman, who is now with the American Locomotive Company. Mr. Hoblitt made his start from New York City, driving to the Alco factory at Providence, then to Boston, and from there to Albany and Buffalo, Cleveland, Chicago, Minneapolis, St. Louis, and all through the Middle West. He said he encountered only a few bad roads, the worst being in Southern Indiana, where rains had caused the Muscatatuck River to rise so that the road was flooded in places. He says: "Most of the time I found good roads and twenty-five per cent. of them were splendid, although I had a car, of course, which makes the worst roads seem fair. The country seemed prosperous everywhere, and I could see nothing but the best of prospects in a business way. I suppose it is known here now, for it is some time since I went over it, but all tourists should be told that the new State road between Albany and Buffalo, which has been so much avoided, is now practically finished all the way." Mr. Hoblitt met with the usual experiences of the road, some laughable and some annoying. In Kentucky the drivers of teams and carriages seemed particularly timid, although the horses gave little trouble. It was during the first weeks of this trip that the famous adventure of the horse-fly occurred, which was widely published in the trade papers and caused great merriment among Mr. Hoblitt's friends, who are sure to remind him of it when he returns.

HOW LEBANON, O., STOPPED SPEEDING

Columbus, O., Aug. 30—Drivers of automobiles between this city and Cincinnati are confronted by a most efficient sign placed at the city limits of Lebanon. The inscription reads: "Automobilists! Speak well of Lebanon. May we speak well of you? Drive Slowly." The result of this polite and reasonable request is that the tourists invariably reduce their speed on the city streets, and there has been less of the fast driving in that place than at any en route. The signs might well be copied by towns which are trying in vain to stop the trouble by imperative warnings of arrest for violations.



An Effective Sign for Speeders at Lebanon, O.

WHAT TIRE-TOWN MEN ARE DOING

Akron, O., Sept. 20—The Firestone Tire & Rubber Company has purchased 15 acres of land in South Akron for a new plant to take care of its increased business. The land will be used for a group of large buildings constructed and equipped after the most approved designs, which will be devoted to the manufacture of automobile tires. H. S. Firestone said, in discussing the project, that the company had been offered inducements to go to other cities, but preferred to remain in Akron on account of the facilities and supply of skilled labor to be found there. The Firestone Company entertained its branch managers and salesmen at a banquet last week, held in connection with the annual convention.

W. W. Wuchter, the new manager of the Swinehart Clincher Tire & Rubber Company, announces that the pneumatic tire to be manufactured by that company next year will differ in many respects from the standard type. Details, however, have not been announced. Two new buildings will be erected, one 40 by 100 feet, to be used by the solid tire department, and one 60 by 125 feet for pneumatic tire manufacture. Three new branches, in Boston, Buffalo, N. Y., and Philadelphia, will be established.

Knox that Won First Prize at Recent Westfield Parade

At a recent automobile parade at Westfield, Mass., the winner of the first prize in the decorative division was the Knox car, owned by H. P. Moseley, a leading lawyer of that city. The flowers used in the decorations were wistaria.

OVERLAND CAPITALIZED AT $1,500,000

Toledo, O., Sept. 20—At the annual meeting of the directors of the Overland Automobile Company in Indianapolis last week a complete reorganization of the company was effected. The capital stock has been increased to $1,500,000, this being deemed necessary on account of the rapid expansion of the company's business, and the name has been changed to the Willys-Overland Automobile Company, in recognition of the prominence of President J. N. Willys in the company. Contracts have been awarded for an addition to the Toledo plant to be 91 by 397 feet and three stories in height. This is the second addition since the Overland company took possession a few months ago. This structure will be located on the five-acre plot of ground which was recently purchased.

TAXICABS FLOURISH IN BALTIMORE

Baltimore, Sept. 20—The taxicab business is certainly flourishing in this city. The latest deal is the purchase of the Belvidere Hansom Company by the Taxicab Company of Baltimore. The latter, by this purchase, gains the right to serve all the hotels of the city, except the Rennert, and the Union Station, and during the next month will place 28 additional cars in service. The company has leased the stables at 413 North Howard street and will convert them into a garage. The Rennert Hotel is to use the taxicab service of the Harry L. Stewart Company.

President Taft in Chicago with Four Chalmers-Detroits as Guard of Honor

On the occasion of the President's recent visit to Chicago there was held an automobile parade through the parks, in which he took a prominent part. Although seated in a Thomas "Six," Mr. Taft had for an escort four Chalmers-Detroit cars, each carrying, besides the driver, a member of the police or Government secret service

Commercial Car from Spokane, Wash.—The Spokane Motor Car Company has been incorporated with a capital stock of $600,000 to manufacture an automobile truck with a four-wheel drive. The company is headed by V. E. Funkhouser, president; Edward Schulmerich, vice-president; F. M. Skiff, secretary; A. L. MacLeod, treasurer, and Thomas Bilyeu, general manager. The truck is claimed to be capable of very short turns, and can pass over considerable obstacles without disturbing the level of its platform. Models will be built of capacity from one and one-half to seven tons. The factory will be located at Spokane, and, it is said, will employ 150 men.

Stearns and Fisk Good Combination—George C. Row, of Chicago, who has just completed a trip from that city to San Francisco in his Stearns car, says that he was surprised by the remarkable performance of his Fisk tires. In crossing the Rocky Mountains he had expected considerable tire trouble, but only one puncture, the work of a sharp nail, was experienced throughout the trip. Mr. Row stated that his car, with its load, weighed 6,200 pounds, and that, although the tires showed the effects of the hard usage to which they had been subjected, they were in perfectly sound condition when the Golden Gate was reached.

New Concern to Make Trucks—The Robinson-Loomis Motor Truck Company, of Minneapolis, Minn., has been organized with a capital of $50,000 to manufacture a truck to be known as the Gopher. The plant will be located on Second avenue north and Seventh street. Besides making the new truck the company will continue to act as agents for the Reliance trucks. T. F. Robinson is the president of the new concern; F. P. Robinson, vice-president, and F. L. Loomis, secretary. Mr. Loomis was formerly sales manager of the Reliance Motor Truck Company, of Detroit and Owosso, Mich.

Firestone a "Live One"—Several New York automobilists who use Firestone tires were winners at the Sheepshead Bay track last week by playing a rather unusual tip. While looking over the list of starters one of them discovered a horse named Firestone entered in the fourth race. Though he knew nothing of horse racing or of the merits of the entries, he liked the name, and, with several of his friends, he bet on the horse. Firestone upheld the honor of his name by coming home a winner, and the users of Firestone tires left the track with $4 in their pockets for every one they had bet.

Maxwells Score at White Plains—In the races held under the auspices of the Westchester Driving Club on its half-mile track at White Plains, N. Y., recently, the two 22-horsepower Maxwells which had just returned from the Lowell meet made a clean sweep in the 10 and 15-mile events. In the former Thomas Costello and Arthur See took first and second honors, and were at no time in danger of being overtaken. The winner's time was 14:20. The 15-mile event was closely contested. Costello was first in 21:32, a Mercedes second and See third.

Reo Successful in Wilmington Service—A Reo car, purchased recently by the city of Wilmington, Del., for the use of its street and sewer department, is proving a great success. It is used by the directors in trips of inspection and has greatly facilitated the work. The Reo is the first machine to be bought by the city but more are contemplated, and the fire department is making arrangements to add two automobile fire engines to its equipment. Negotiations are already progressing with the manufacturers of these cars.

Ohio Electric Company Reorganized—The Ohio Electric Company, incorporated during the past week by H. P. Dodge and other Toledoans, with a capital of $75,000, will take over the business of the Ohio Electric Carriage Company, which was organized some months ago for the manufacture of electric vehicles. For the present the company will only assemble the various parts which are to be made under contract, but ultimately it is the intention of the company to build a factory with sufficient capacity to build the greater portion of their machines.

W. C. P. Taxis Parade at Coney—In the Mardi Gras parade at Coney Island, the climax of the season at New York's popular seashore resort, Police Inspector O'Brien and Captain Fennelly, with the executive committee of 26 men, headed the line in the yellow taxicabs of the W. C. P. Company. The cabs were artistically decorated and drew much favorable comment through their fresh and clean appearance, in spite of the fact that most of them have been in hard service since June 1.

Franklin Crosses Mont Cenis—George T. Odell and party, of Salt Lake City, Utah, have just returned from a 9000-mile European tour in a six-cylinder Franklin. They crossed Mont Cenis on the new road at an altitude of between 7000 and 8000 feet. There was considerable snow met with, but the 30-mile run between Mondane and Sousa was made in an hour and a half. Another achievement was the climbing of Mount Vesuvius to a point beyond that reached by the tramway.

Driggs-Seabury Drops Ordnance—The Driggs-Seabury Ordnance Corporation will discontinue the manufacture of ordnance as soon as contracts on hand are filled, according to reports. The company henceforth will devote all its time to the manufacture of automobile parts. Since that branch was taken up some time ago orders have been coming in rapidly and at present there is enough work on hand to keep the factory busy for several months.

Hoosiers Want a Truck Factory—At a meeting of Ft. Wayne, Ind., capitalists recently it was voted to finance the transfer of the Coppock Motor Car Company, of Decatur, Ind., to that city. A thorough investigation gave very favorable results and it was decided that the establishment of the factory in Ft. Wayne would be beneficial to the interests of the city. It is planned to raise $100,000 capital to finance the company.

Hartford Company Elects Officers—At the recent meeting of the directors of the Hartford Auto Parts Company, of Hartford, Conn., W. H. Caldwell was elected president and treasurer, F. H. Bogart, vice-president and manager, and F. L. Martin, secretary. Messrs. Caldwell and Bogart, and T. H. Brady, J. J. Amgulatis, John Boyle and E. W. Putnam were elected directors.

Connecticut Authorities in Earnest—That the Connecticut secretary of state means business, and will not tolerate the reckless operation of automobiles, is made plain by the revocation of a license announced in the case of the driver of G. A. Schwartz of Chicago, who maintains a summer home in Suffield. The driver in question struck a pedestrian a few days ago.

Whitney Parts in Demand—The Whitney Manufacturing Company, of Hartford, Conn., plans an immediate addition to its present four-story structure in order to accommodate its increasing business. A temporary addition will be built to enable the company to keep pace with its orders during the winter, and in the spring a permanent concrete addition will be built.

Philadelphia Supply-Men Picnic—The annual Labor Day picnic of the employees of the big Philadelphia accessories establishment of James L. Gibney &

Brother was held this year at Hamilton's Farm, near Chester. The Benedicts slaughtered their unmarried fellow-workers at baseball by the score of 35 to 15.

New Six from an Illinois Town—C. E. Lipman, of Beloit, Wis., a manufacturer of automobile parts, is interesting the capitalists of Rockford, Ill., in his plans for a six-cylinder, 36-horsepower car, which it is proposed to name the "Rocoit." If the plans are carried out, production will begin about January 1. The car will sell for less than $2000.

Clever Thermoid Advertising—Automobile dealers have been periodically receiving ingenious folding post-cards from the Thermoid Rubber Company, of Trenton, N. J., extolling the virtues of Thermoid brake lining. "Good Reasons," "All in a Nutshell," "Think It Over!" and "The Stamp of Approval" are some of the titles.

New Maker of Blomstrom Cars—The Lion Motor Company, which was recently organized in Detroit, with a capital of $300,000, is to move to Adrian, Mich. The company is to manufacture the Blomstrom and Gyroscope cars, designed by Charles E. Blomstrom, of Detroit, and expects to have its machine on the market by the first of the year.

IN AND ABOUT THE AGENCIES

Elmore, New York City—Peter Fogarty and George Post has secured the Elmore agency formerly held by A. E. Ranney & Company, and will open an office on West Fifty-fourth street, near the A. C. A. club house. Mr. Fogarty held the Northern agency until that company was merged into the E. M. F., and has since been connected with the Marmon interests. Mr. Post was formerly connected with the American Panhard branch. The new firm will be known as the Elmore Motor Car Company of New York.

Studebaker, Philadelphia—The Philadelphia branch of the Studebaker Brothers Company is to give up its present quarters at 330 North Broad street to move into the 80 by 200-foot, three-story building at Pennsylvania avenue, Eighteenth and Noble streets. Manager F. V. Stratton expects to get into the new quarters in two weeks.

Oldsmobile, Baltimore—A modern building, embracing garage, sales and repair shop facilities, will soon be erected for the Baltimore headquarters of the Oldsmobile. E. L. Leinbach, the manager, is now making arrangements for the shipment of 1910 cars, and reports that his prospects for the coming season are even brighter than they were at the beginning of the present highly successful one.

Reo, Hupmobile and Oakland, Baltimore—The "Little Joe" Weisenfeld Company will occupy the building at 14 North Howard street as an auto exchange for the Reo, Hupmobile and Oakland cars. The building has four floors, and is 35 by 105 feet. It was leased by the company last week.

Kline-Kar, Philadelphia—The B. C. K. Motor Car Company, of York, Pa., which is making the Kline-Kar, has installed a branch office in the establishment of Frink & Company, the well known carriage makers, at 203 North Broad street.

Haynes, Atlanta, Ga.—The Corker Motor Car Company has been appointed agent for the Haynes in Georgia, Florida, Alabama, Tennessee and North and South Carolina. This company also holds the local agency for the Matheson.

Rambler, Brooklyn, N. Y.—Thomas B. Jeffery & Co. have made arrangements with the Kenny Motor Car Company to act as Rambler distributors in Brooklyn. A garage will be erected at Sterling Place and Bedford avenue.

Lozier, Hartford, Conn.—Brown, Thompson & Co., of Hartford, Conn., have been appointed agents for the Lozier car for the State of Connecticut, with the exception of the counties of Fairfield and New Haven.

Alco and Pullman, Philadelphia—W. C. Longstreth has secured the agency for the Alco in the Quaker City and adjacent territory, and last week announced in addition the acquisition of the Pullman sales agency.

Maxwell and Bailey, Cincinnati—The Chas. Behlen Sons Company, a prominent carriage maker of this city, located at Fifteenth and Vine streets, has taken the selling agency for the Maxwell and Bailey electric.

Pierce-Arrow, Louisville, Ky.—A company has been formed under the name of the R. H. Semple Company to handle the Pierce line in this city. The present location is at 309 West Main street.

Luco "Night Pilot," New York—This device will be sold through the Luco Night Pilot Company, 1777 Broadway.

PERSONAL TRADE MENTION

A. S. Holden, at present assistant sales manager of the F. B. Stearns Company, will assume, about October 1, the position of Western Manager, with headquarters at San Francisco. His territory will extend from Salt Lake City to the coast and from the Mexican to the Canadian boundary.

Asa Goddard, formerly president of the Worcester, Mass., Automobile Club, and later secretary of the Cleveland Automobile Club, has taken the position of general sales agent of the Kelly-Springfield Road Roller Company, of Springfield, Ohio, for which he has been fitted by his extensive experience in road-building.

James C. Howell, of Cornwall-on-the-Hudson, N. Y., has been appointed assistant manager of the Warner Instrument Company, of Beloit, Wis., to succeed Alfred S. Koto, resigned. Mr. Howell is a graduate of Columbia and has specialized in patent law.

H. J. Snider, who recently entered the employ of the H. H. Franklin Manufacturing Company as assistant to one of the office department managers, has been promoted to the management of the Albany, N. Y., branch of the company.

W. A. Rutz, formerly traveling representative of the New Departure Company, Bristol, Conn., has accepted a similar position with the Gilbert Manufacturing Company and the F. E. Bowers Company of New Haven, Conn.

Albert C. Galbraith has accepted a position with the Continental Caoutchouc Company, of New York, and will travel from the Philadelphia branch, covering Pennsylvania. He formerly represented the Diamond Rubber Company in the New England territory.

Thomas W. Simpson, formerly of the York Motor Car Company, of York, Pa., has joined the salesforce of "Little Joe" Weisenfeld, the Baltimore representative of the Reo, Oakland and Hupmobile cars.

David W. Pell, formerly superintendent of the Electric Vehicle Company in Hartford, Conn., has been made general manager of the recently organized Pell Motor Car Company, of Oswego, N. Y.

L. L. Dunlap, formerly factory manager of the Oakland Motor Car Company, Pontiac, Mich., was appointed general manager at the director's meeting this week to succeed the late E. M. Murphy.

Hobart M. Adams has been appointed general sales manager of the Royal Motor Car Company, of Cleveland. Mr. Adams formerly managed the Cleveland branch of the White Company.

Herman Eckhardt, Jr., after a year's absence, has returned to the employ of the Columbus Buggy Company, of Columbus, Ohio, as sales manager of its electric and gasoline cars.

E. B. Lausier has been appointed assistant sales manager of the Timken-Detroit Axle Company, of Detroit, and of the Timken Roller Bearing Co., Canton, O.

Factory and Offices of the Fal Motor Company, at Chicago

Ajax Cup for Runabouts in "Star" Tour

DE LISSER TROPHY FOR WESTERN TOUR

Kansas City, Mo., Sept. 18—Horace De Lisser, president of the Ajax-Grieb Rubber Company, has offered a handsome trophy, to be known as the Ajax Cup, for the reliability tour which starts at this city Monday. This cup will be awarded to that contestant in the runabout division, either dealer's or owner's class, who crosses the finish line with the best score. The tour, which will last five days, and cover a distance of 675 miles, will take in Junction City, Kan.; Lincoln, Neb.; Omaha, and St. Joseph, Mo.

DOUBLE SUIT OVER MOSLER PLUGS

An injunction suit has been filed against A. R. Mosler & Company by the Lehman Manufacturing Company to restrain the former from manufacturing spark plugs claimed to infringe on patents granted to J. H. Lehman October 20, 1903. The Mosler Company says that its plugs do not infringe, and intends to fight the case in the courts. On the other hand, the Mosler Company has begun a suit against the Auto Supply Company for infringement on the Canfield patent, granted October 18, 1898, covering a spark plug with a recess around the electrode for the purpose of preventing soot from gathering on the insulation. This patent, with two others, is now the property of the Mosler Company, which claims that a majority of the spark plugs now in use are infringements.

YORK-PULLMAN DIRECTORS MEET

York, Pa., Sept. 18—The annual meeting of the board of directors of the York Motor Car Company, maker of the Pullman cars, was held this week. A dividend of 7 per cent. was declared. T. C. O'Connor was elected president, O. Stevenson was re-elected secretary and treasurer and George S. Schmidt was made a member of the board of directors and counsel for the company. A considerable amount of the year's earnings was set aside as surplus.

NEW YORK TRADESMEN'S GAMES

The inhabitants of New York's automobile row turned out last Saturday for an outing at Lange's Grove, New Dorp, S. I., and donned running pants and jerseys in place of the conventional duster and goggles. The outing took the form of a track meet, and there was some spirited competition. Although the events were open only to members of the organization, sufficient entries were received to make them unusually interesting. W. Flynn, of the Diamond Rubber Company, outscored all the other contestants, winning the 100-yard dash, the hop, step and jump.

FIRST NEWS OF EVERITT "THIRTY"

Detroit, Sept. 20—William E. Metzger, B. F. Everitt and William Kelly, who recently disposed of their holdings in the E.-M.-F. Company to Studebaker interests, are sponsors for a new car that will shortly make its appearance. Details have been kept under cover, but it is known that the car, which is a Kelly creation, will have a four-cylinder motor developing 30 horsepower. It will be built in two styles, listing at $1,250 and $1,400. A factory has been secured, and following the incorporation of the new company, which will be effected shortly, the manufacture of cars for the 1910 trade will be undertaken. It is reported that they have purchased the Meier trunk factory on the line of the Grand Trunk Railroad, and will proceed to build a large addition, such as to permit of the building of 5,000 cars, both runabouts and touring cars. for the coming year.

DETROIT'S LATEST WARREN-DETROIT

Detroit, Sept. 20—The Warren Motor Car Company is the latest to loom above the local horizon, where the incorporation of an automobile manufacturing concern is almost a weekly occurrence. The company is capitalized at $100,000, and the cars put out will be of the light runabout and touring type. The new machine will be known as the Warren-Detroit, and will be on the market early in 1910.

The incorporators include Postmaster Homer Warren, C. R. Wilson, of the Wilson Body Company; Harry N. Snyder, R. J. Brennan, W. H. Radford, formerly assistant engineer of the Hudson Motor Car Company; Henry C. Walters and J. Bayerline, formerly purchasing agent for the Hudson Motor Car Company.

GRAMM-LOGAN INCREASES CAPITAL

Bowling Green, O., Sept. 18—The first fiscal year of the Gramm-Logan Motor Car Company, which ended this week, was very satisfactory to the stockholders. The directors declared a cash dividend and laid by a surplus fund in addition. A. L. White was elected president, B. A. Gramm was re-elected vice-president and general manager, and F. E. Lamb and J. B. Wilson were elected secretary and treasurer, respectively. It was unanimously agreed to increase the capitalization of the company from $100,000 to $300,000.

REO EMPLOYEES GET BONUS

Lansing, Mich., Sept. 20—The Reo Motor Car Company has presented its employees who have been with the company for a year a check for an amount equaling 5 per cent. of their year's wages. The wage dividend amounted to about $10,000—$3,000 more than last year at the same rate.

TAXICABS AND TRANSIT

Peoria, Ill.—The Palace Boarding & Livery Stable of Peoria, Ill., has decided to enter the automobile taxicab business, and has placed an order with the Sultan Motor Company, of New York, for a number of Sultan machines.

Great Western at High Bridge, Ky.

C. A. Kenney, the owner of the Great Western car shown, has driven it 3,450 miles in the past two months. The "Towers," at High Bridge, Ky., were originally intended to support a suspension bridge, but after they had been built the project was abandoned.

NEW AGENCIES ESTABLISHED

Alco and Stoddard-Dayton: Providence, R. I.—Park Square Automobile Station, 17 Snow street.

American and Maxwell: Seattle, Wash.—Polson Implement Company, 926 First avenue South.

RECENT INCORPORATIONS

Fleis Equipment Company, Brooklyn, N. Y.—Incorporated by Charles E. Miller, B. W. D. Woodward, George Bender, W. A. Towner, Jr., and John P. Miller, with a capital of $100,000, to manufacture airships, aeroplanes and balloons.

Automobile Sales & Supply Company, San Antonio, Tex.—Capital $20,000. To manufacture and deal in automobile supplies, accessories and motors cars. Incorporators: Sidney H. Weis, E. A. Kalkhurst, Roy Campbell.

Cataract Motor Company, Paterson, N. J.—Incorporated by Louis A. Piaget, W. H. Sherman, F. W. Freeman, H. J. Westerhoff and G. E. Hannah, with a capital of $350,000, to manufacture motor vehicles, engines, etc.

Pell Motor Car Company, Oswego, N. Y.—Incorporated by Chauncey C. Place, Albert N. Radcliffe and David W. Pell, all of Oswego, with a capital of $150,000, to manufacture automobiles, parts, etc.

Bergen and West Side Motor Car Company, Jersey City, N. J.—Incorporated by Charles E. Collard, Martha L. Collard and Beverly D. Sparks, with a capital of $100,000, to manufacture automobiles.

E. R. Thomas Motor Branch Company, Chicago—Capital $100,000. To do a general automobile and garage business. Incorpoartors: J. Weisenbach, J. J. Cermak, J. S. McClellan.

Marquette Motor Vehicle Company, Chicago—Capital $20,000. To manufacture automobiles, motors and vehicles. Incorporators: Isaac L. Marks, David J. Marks, Isaac B. Lipson.

Allen Taxicab Company, New York—Capital $1,000,000. To operate automobiles, taxicabs and other vehicles. Incorporators: Harry N. Allen, William Halpin, Arthur W. Osborn.

Motor Service Company, Jersey City, N. J.—H. L. Lechner, Doering Bellinger and W. G. Jones, incorporated with a capital of $100,000 to manufacture vehicles of all kinds.

Badger Auto Company, Oshkosh, Wis.—Capital $50,000. To manufacture automobiles. Incorporators: M. L. Cottrill, L. J. Monahan, J. D. Termaat, E. H. Fahrney.

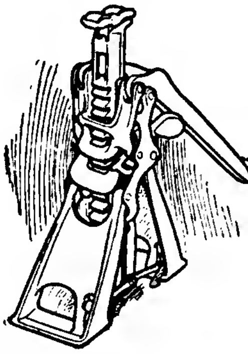
Information for Auto Users

S. & W. Auto Crank—This is a device intended to avoid the necessity of leaving the seat in order to crank the motor. It has no resemblance to the ordinary starting device, as it merely replaces the crank in front of the machine. It consists of a countershaft running along the motor, connected at the front end to the crankshaft by means of a sprocket, chain and ratchet device, and at the rear end to a crank suitably mounted on the dash. The ratchet on the crankshaft disconnects the countershaft and gearing as soon as the motor starts, so that there is no extra machinery in motion when the car is running. The device is claimed to be much simpler than any of the compressed air or coil spring starters, and

OPERATION OF S. & W. CRANK

has the additional merit of being absolutely positive; it will start the motor any time that the ordinary crank will start it. As there is a considerable gear reduction in the sprockets, the dash crank is very easy to turn. There is also no possibility of a back kick. The makers are Stryker & Woessner, Huron, Ohio.

Spitzli Ratchet Auto Jack—No one has yet invented a way of dispensing with jacks, or of avoiding the occasions which necessitate their use; meanwhile, the best that can be done is to make the jack as compact and easily operated as possible. This has been the aim of the Spitzli Manufacturing Company, of Utica, N. Y., in designing its ratchet jack. It is compact in form and light in weight, and at the same time capable of handling heavy loads. The principle on which it is built enables the user to get a tremendous leverage. The jack works with either the hand or foot, and is instantly adjustable to the height of the axle. With every downward stroke of the handle the load is lifted half an inch, the special toggles then catch hold in such a way that it is impossible for the load to slip back. The action is easily reversible, so that the same downward stroke will lower the vehicle. The jack has a folding base, which expands to an unusual width, making it very steady in action. The jack fits under and out of the way of brace rods and trusses, and is especially desirable for use with overhanging tonneau or taxicab bodies. As an instance of its compactness and light weight, the



SPITZLI JACK IS VERY COMPACT

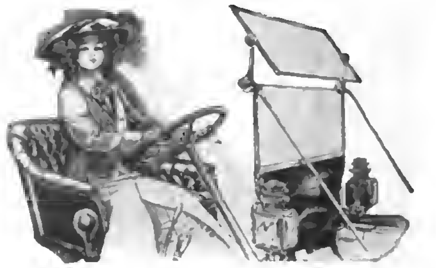
maker of the jack states that the No. 12 size, which is tested to lift automobiles up to 4000 pounds in weight, and is guaranteed against breakage or failure in operation, weighs only about 5½ pounds, and when folded occupies a space in the toolbox approximately 10½ by 3 by 3 inches.

Luco Swinging Lamp Bracket—The Luco "Night Pilot," brought out by the Luco Manufacturing Company, of Dalton, Mass., is an improvement on former designs of headlight brackets intended to swing the lamps when the car makes a turn. The principal difference is that only one of the lamps, that on the driver's side of the car, is movable, and it is operated directly from the steering gear instead of from the front wheels. One lamp thus remains pointing straight ahead, lighting up the side of the turn in the car's immediate vicinity, while the other points down the road which the car is about to take. When not in use the bracket is

NIGHT PILOT LAMP BRACKET IN USE

firmly locked. It is supported on ball bearings, and the few working parts are so constructed that they cannot rattle, whether in operation or not. The device operates very easily, and the additional effort necessary to move it, in addition to the steering, is not noticeable. It can be attached in 20 minutes, without drilling or otherwise weakening the construction, and is unobtrusive in appearance. The moveable fork of the "Night Pilot" simply replaces the fixed one with a few simple connections; the same headlights are, of course, used, so that the total expense is but the cost of the device itself and a few minutes' labor.

Troy Automatic Windshield — The Sextette, as it is called by the maker, the Troy Carriage Sunshade Company, of Troy, Ohio, is capable of assuming six different positions, each of which will be found advantageous under certain combinations of circumstances. The first position, of course, is with both halves in line and vertical, as in the original form of windshield. The next is with the upper half folded down flat against the lower. Then come the special positions which lend the "Troy" its particular value. The upper glass is carried on hinged supports on either side at about the middle of its height. It can be tilted back on these supports to an angle of about 30 degrees from the vertical, so as to deflect the air currents upward, while at the same time the lower edge swings forward, leaving an open slit through which the driver can clearly see the road, no matter how wet the glass itself becomes. In warm weather, or when the bottom of the car heats up, this position can be reversed, the upper edge swinging forward and the lower edge back, so that the air is deflected into the car, striking about the knees of the front seat passengers. For drivers who believe that it distorts the vision to look through a slanting glass, the same effect can be secured with the upper glass vertical, parallel to the lower, but six inches to the rear of it. Or, finally, the upper glass can be tilted back



SEXTETTE WIND SHIELD PARTLY DOWN

with its lower edge still touching the other glass. In this position the upper glass is in line with the slanting stay-rods, giving it a very neat appearance. All positions are acquired automatically without set screws; the upper glass locks positively in position, and all parts are held together by a stiff spring so that they cannot rattle.

Osgood Automatic Lubricator—It is no longer necessary to argue for or against the use of a force-feed lubricator; their use is taken for granted. Among the newcomers in this line is the J. L. Osgood Lubricator Company, Buffalo, N. Y., with an oiler which has a number of new features. Some of these are the entire elimination of the usual bleeder test, absence of needle or throttle valves, the use of very simple pumps and the attachment of the same to the cover, so that the removal of the cover screws and the drive shaft allows of removing the whole lubricator bodily. Another worthy feature is the use of white celluloid discs for the regulating knobs.

THE AUTOMOBILE

MUNSEYITES COMPLETE RELIABILITY

WASHINGTON, D. C., Sept. 29—Back into Washington this afternoon came the survivors of what was known as the "Frank A. Munsey Reliability Contest," these autos having made the journey from the "Capital City" to Boston and return, a distance of 1,282.2 miles, accomplished in seven running days, and mostly in weather that resulted in precarious highways except where the road construction had been of the most up-to-date kind. The route embraced the most important cities of the Atlantic States traversed, night stops including Philadelphia, Boston and New York City.

Of course, it is impossible at this moment to give a list of the winners, for these will not be announced until after Technicists Trego, Overpeck and Cassard complete their minute observations, which are likely to occupy a day or more. It is the intention of the management of the tour, and all contestants have been fully warned of it, to make this examination more than usually thorough.

It was natural that with the event promoted by one particular string of newspapers, it did not receive any vast attention from other sources; hence, the participants found that the Washington *Times*, Boston *Journal*, Baltimore *News* and Philadelphia *Times* were the only papers which gave front-page stories. In consequence, there were disappointments at the comparatively limited amount of publicity forthcoming, which, in one instance, caused a couple of withdrawals. Nevertheless, a commensurate amount of space was utilized in telling the story of the run, and the successful ones will have opportunity of exploiting their prowess.

The decidedly unfavorable weather conditions added most substantially to the difficulties of the task, which duplicated, in some degree, the strenuousness of this year's Glidden tour. The announcement of the complete score and penalizations will be forthcoming at the earliest possible moment.

When the contesting cars in the run checked in at Philadelphia at the close of the sixth day's running, Referee Trego announced that the standing of the cars would not be announced until after the final examination in Washington at the conclusion of the tour. Twenty-one cars still remain in the tour, the withdrawals since the departure from Boston being the two Croxton-Keetons. While it is expected several of the cars will have perfect road scores, the chances are all against any car having a perfect mechanical score when the technical committee finishes with the examination and measurement of the contesting machines. For severe road conditions no tours in the famous Glidden tour to Pittsburg compares with the Munsey contest. Rain has been the portion of the Munseyites for nearly a week and they were heartily glad to see the sun shine just after crossing the Staten Island ferry in the morning. This put new life into the tourists and they thoroughly enjoyed the run from New York to Philadelphia by way of Atlantic City.

Connecticut Supplied Some Excellent Highway, Near Birdgeport

After two ferry trips and a short jaunt across Staten Island, the tourists proceeded along the Eastern coast of New Jersey, nearly due south over the excellent though low roads of that State. Passing through the Amboys, many of the smaller but important towns were touched, including Lakewood, Tom's River, the county seat of Ocean county, Barnegat, Egg Harbor City, and so on into Atlantic City. Spending but a few hours in Philadelphia's playground, they turned northwest, and started out for the city itself, 57.4 miles away.

SECOND DAY: PHILADELPHIA TO MILFORD

132.6 MILES

MILFORD, PA., Sept. 22—To-day's run was a veritable "joy-ride." Although the sun shone but a few minutes throughout the day and rain constantly threatened, it was not until all hands were within a few miles of this place that oilskins and rubber coats had to be resorted to. The roads—mile after mile of them oiled—were in ideal shape for fast work, but the committee, for some unknown reason, reduced the limit of the big cars to 18 miles an hour and the others accordingly. The result was that at each control there were long waits. Indeed, so heavily did time hang on its hands that the committee ordered an unofficial half-hour stop at Rittersville, where the Lehigh Valley Motor Club surprised the tourists with lunch and beverages.

At Allentown the first break was made in the line-up by the enforced

Referee F. H. Trego

withdrawal of Selden No. 34, by Owner-Driver Patterson, due to the receipt of a telegram requiring his immediate presence in Philadelphia to look after the details of a lawsuit. In the same city a serious accident occurred to Mrs. Hall, wife of the owner of Columbia No. 15. At a slippery right-angled turn at the foot of a hilly street the car skidded into the curb, dishing a wheel, splitting the car body and throwing Mrs. Hall against Observer G. B. Emerson, breaking her collar-bone. The observer was uninjured and came on to Milford in Croxton-Keeton No. 16, having been informed by Owner Hall that the car was withdrawn. Later the latter changed his mind, and, securing a new wheel, ordered Driver Jacobi to proceed, he staying in Allentown with Mrs. Hall. Jacobi was in a quandary as to passengers, but finally lived up to the rules by paying $5 apiece to two outsiders to occupy the tonneau as far as Milford. He arrived here about midnight at a cost of 354 demerits for lateness and 28.7 for work and cost of material.

Corbin No. 18 met with a peculiar mishap. In some manner a small nut dropped into the differential and stripped the gears. Driver Goss managed to reach Allentown, where he wired to New York for new parts. By fast work he managed to complete repairs at 9.30 and pushed on to this place, arriving shortly after 1 o'clock in the morning.

Driver Behrens, of Maryland No. 11, saved a penalty to-day by quick thinking. On a long rise near the Delaware Water Gap his motor began to slow down owing to a short fuel supply. Quickly reversing his car to expedite the flow of gasoline from his nearly depleted tank, he backed slowly up the hill and managed to keep his engine going till a good Samaritan among the contestants let him have a spare five-gallon can he was carrying for emergencies.

The excellent roads and the easy schedule were responsible for the comparatively few penalties inflicted on the second day. Two cars, however, were eliminated from the clean-score list—Pullman No. 37 in the third division, which was punished .8 for work on axle bearing and differential, 2.0 for work on clutch, .1 for examining plug, .6 for work on same and .1 for cost, a total of 3.6; and the American Simplex in the fifth division, which suffered to the extent of .1 for starting motor. No. 7 Ford added .3 to its first day's total—.2 for starting motor and .1 for adjusting carbureter. Washington No. 5 received an additional .1 for tightening fender bolt. "Billy" Knipper's Chalmers-Detroit No. 1 added 1.5 to its first day's total—1.2 for work on a broken fender, .1 for cost of material, .1 for oiling and .1 for starting motor, the latter due to a too-quick shut-down to avoid a collision with the chairman's car, which he had been following like a shadow all day. The heaviest sufferer of the day was Croxton-Keeton No. 16, whose 4.3 demerits were made up of 4.1 for work on universal joint and .2 for cost of material (the latter a double penalty for not carrying same in the car). In addition to the 1,000 points penalty for withdrawal, Selden No. 34 had a few tenths handed to it for work and cost of material, but just what they were was not announced.

Committeeman Overpeck

THIRD DAY: MILFORD TO ALBANY

158.5 MILES

ALBANY, N. Y., Sept. 23—The close of the third day of the run saw but an even half-dozen cars figuring in the clean-score class. Maryland No. 11 was ditched near New Baltimore as a result of a locked steering gear. The latter had been strained at Kingston, when Driver Behrens sent his car up a high curb to avoid an accident. While nearing New Baltimore a left turn of the hairpin variety was encountered and when the gear locked

Lining Up on Jerome Avenue, in New York City, for the Procession to the Waldorf-Astoria

Massachusetts State Highway Encountered Before It Had Received the Finishing Touches of the Roadsmaker

the Maryland went into the fence, tearing down half a dozen panels and coming up standing sidewise on the steep incline. It was remarkable that no one was hurt. The angle at which the car stood when finally stopped was so acute that the exertion of but a few pounds would have sent it bottom-side up. Jesse L. Cassard, Jr., of Baltimore, a member of the technical committee, who was a passenger on the car, was projected 20 feet down the hill, but came off unscathed, apart from the loss of nerve natural to such a mishap. He will train it to Boston to-morrow. The car suffered a badly bent axle and additional injury to its steering gear, but it was reported to-night that the crew hoped to get the car out and fixed up in time to get to Boston a day behind the run.

Washington No. 5 was also disabled. The drive shaft kept slipping out at the universal joint until, when Athens was reached, the crew decided to stop at a blacksmith shop and make a part which was necessary to a permanent repair. Observer Howard L. Cole left the car and came on to this place, but it is reported that the Washington will continue as soon as repairs are completed.

Twelve miles out of Newburg Driver McBurney, of Matheson No. 27, was threatened with a shotgun by an irate farmer, some of whose poultry was immolated by an early car. He looked as if he meant business, too, but McBurney, after he got close to him, threw on his high and bounded away, all hands meanwhile ducking to avoid the shot which they thought was surely coming.

The rain, which began yesterday, continued intermittently throughout the day until Catskill was reached, when the tourists ran ahead of the storm, which was apparently headed in the same direction, for in some sections the roads were inordinately dusty. From oilskins and tire chains all the morning to dusters in the afternoon, the transition was so sudden as to excite remark, and the appearance of cars and passengers as a result of the combination was harrowing.

Coming up the Hudson from Newburg, a forage pack train of 73 mules in charge of a squad of United States cavalry was encountered. The mules seemed to object strenuously to the presence of the cars, and several of them gave indication of registering their objections in the manner common to their kind. But the kind-hearted sergeant in charge solved the problem of the passage of the cars past the long line of animated stubbornness by detailing one of his men to convoy each car to the front.

"Billy" Knipper, driver of Chalmers-Detroit No. 1, in which THE AUTOMOBILE man had a seat, showed the effects of his recent Southwestern pathfinding experiences by the clever manner in which he avoided a mix-up with a female bovine with a crumpled horn. As the blue car came along, Bossy, which was one of a "flock," lowered her head and made a rush. "Billy" saw a bull-fight down in Mexico, and, waiting till the proper moment, dodged his car around the astonished cow in a manner which would have made an expert matador turn green with envy. At that, the crumpled horn came near hooking the rear wheel.

Referee Trego received last night from Charles J. Glidden a telegram congratulating him and the other officials on the success of the run up to date and expressing his regrets at his inability to form one of the party.

The only foreign car in the run, the Renault "20-30," is giving an excellent account of itself. Driver Leo Shaab lands his car among the leaders at every control, and withal drives so carefully that he is among the very, very few who have not as yet been compelled to get busy on tires.

The little 18-20 Autocar truck, as usual, was on hand early this evening with the extra baggage. Driver Thacher reports an utter absence of trouble up to date.

To-day, for the first, time began to figure prominently in the penalizations. As a starter, the committee figured up a total of 382.7 for the Columbia No. 15, which accumulated that high total as a result of its Allentown accident. Of this amount 354 points were for late arrival, the remainder being made up of 25.7 for work and 3.0 for cost of material. The little Hupmobile No. 29 added .4 for work in adjusting carbureter. Reo No. 26 left the clean-score class by reason of 4 points penalty for as many minutes' lateness in reporting at Albany.

Pullman No. 12, in addition to 30 points for late arrival at Albany, was penalized 36.7 for work on fanshaft and .6 for cost of material—a total of 67.3 for the day. Crawford No. 24 was another to leave the clean-score class on the third day, its observer's card showing work on lamp bracket to the extent of .3 and .1 for starting motor. Washington No. 31 accumulated 31.2 demerits during the day—31 for late arrival here and .2 for starting motor. The 2.2 collected by its sister, Washington No. 32, were 2 for late arrival here, .1 for starting motor and .1 for work on springs.

Croxton-Keeton No. 16 had spark-plug trouble during the day, which cost it 1.1 points penalty—.9 for work and .2 for cost of material. Matheson No. 27 also gathered 1.1 demerits for the day by reason of work on mud-pan to the extent of .8; labor

An Incident Near Baltimore, Where One Car Demolished a Bit of Fence

on fender, .2, and cost, .1. Pullman No. 37, which failed to report here this evening, was withdrawn, the car being shipped to New York from Saugerties by boat. It is understood that the cause of the withdrawal was trouble with the rear axle.

FOURTH DAY: ALBANY TO BOSTON

194.2 MILES

BOSTON, Sept. 26—The fourth leg of the run was a veritable mud plug. Eleven hours of rain, which increased in severity the nearer the Hub was approached, made the going anything but comfortable to the tourists, although, fortunately, the roads were excellent, being especially good between Springfield and Boston. None of the six clean-score cars suffered penalization, and despite the downpour the drivers were so careful that no less than 17 of the 23 cars still in the run scored clean for the most hazardous day thus far.

Jacob's Ladder, that succession of bumps over the backbone of the Berkshires, came near proving the undoing of several of the clean-scorers. During a furious downpour they were blocked by one of the Washingtons, which slipped into the ditch and partly blocked the road. At one time there were a dozen cars endeavoring either to slip around the obstruction or quietly clinging to their places on the slippery mountain, confident that in the event of lateness at controls a wise referee would absolve them from punishment. Several of them stalled motors endeavoring to get around, the ditch being of such depth that it required the services of man-power to get the wheels on comparatively solid ground again. Even these were let off scatheless.

So heavy was the rain and so muddy the clothes and hands of drivers, observers and passengers, who all helped the ditched car on to terra firma, that the observers' cards were in many instances undecipherable. Referee Trego and his assistants had their own troubles calculating the penalties, but by questioning the observers they managed to get the facts.

Washington No. 31 rolled up 358.1 demerits for the day, due to a skid into a telegraph pole at a right-angled turn in Westfield, outside of Worcester. The resultant bent axle had to be taken out, put in the fire at a nearby blacksmith shop and straightened before the car could proceed.

Unlucky Maryland No. 11 added 118.6 to its already large total, due to a bent axle following a skid. The car did not get away from Coxsackie, where it was ditched, until 4 o'clock Saturday afternoon, and Driver Behrens, who had had no sleep for 36 hours, kept right on, reporting at Albany at 5.19 and at Boston at 6.15 A. M. Sunday, after an all-night drive over the length of Massachusetts.

Columbia No. 15 suffered from a broken connecting rod, which delayed the car over eight hours and rolled up a penalty of 567.3 points for the day. The E-M-F pilot car lost a wheel and was held up for many hours, throwing all the confetti work on its confrere, the Midland. The irrepressible and ubiquitous Spooner, on whom all the photographic work has fallen since the Lazarnick representative abandoned the run at Philadelphia, was compelled to stop work absolutely, owing to the weather, and Joe Matson, relieved of the necessity of stopping frequently, drove "Mike the Tramp" through from Albany to Boston in 9 hours 40 minutes.

Various contestants reported four different runaways, but no fatalities. One farmer, whose motor shied at Chalmers No. 1, is minus a wagon and 80 quarts of milk. Although his horse disappeared rapidly over the landscape, he was fair enough to acknowledge to the tourists that "it hain't your fault; that 'ere skittish mare hain't no good nohow."

When the tourists arrived at Boston, Mr. Glidden took the officials in tow and dined them at the Somerset, and later at the impromptu smoker held by the Bay State Automobile Club for the entertainment of the visitors spoke entertainingly of his ballooning experiences. Saturday afternoon the Munsey people acted as hosts at a shore dinner at the Relay House at Bass Point, Nahant. On the way a stop was made at Fort Warren, where the tourists were greatly entertained by the explanations of coast defense tactics as very lucidly explained by two very pleasant officers. On the trip from the fort to Bass Point the small steamer which was chartered for the trip was shaken up so severely that not a few of the tourists began to feel qualms before the tiny craft pulled into the wharf, and as a result about a fourth of the party returned to the Hub by trolley, afraid lest they might lose the good dinner their hosts had provided.

Despite the storm, penalties were not so numerous as on any of the preceding days. In the third division Washington No. 5 was given .6 demerits—.5 for work on the propeller shaft and .1 for starting motor. The 358.1 rolled up by its sister car, No. 31, was mostly for the delay occasioned by a bent axle—340 points—the remainder being made up of 18 points for work and .1 for starting motor. Of the Maryland's total of 118.6, 1 was due to lateness in checking in, 117.5 for work on a bent axle and .1 for starting motor. Columbia No. 15, which now has nearly a thousand demerits chalked up against it, accumulated over half of that large total on the fourth day's run, the 567.3 bad marks being made up of 493 points for lateness at the Boston checking station and 74.3 for work on a broken connecting rod. Matheson's 1.3 was for work on one of the springs, the cost penalty to be added when the run reaches Washington, the price catalogue having been left at the capital.

FIFTH DAY: WILLIMANTIC, CT., TO NEW YORK

NEW YORK, Sept. 27—Twenty-one of the 23 cars remaining in the contest reported here before dark this evening. When the run pulled up at the Waldorf-Astoria the participants were met with an invitation from Frank Munsey to a banquet in the Astor room at 7 o'clock sharp. As a result there were no penalties posted for the day, the officials declaring after the symposium that they were too exhausted to work on mere details. The banquet was one of the pleasantest entertainment features of the tour. After coffee and cigars, Mr. Munsey opened the speechmaking by disclaiming all credit for promoting what has proved such a successful tour, giving the honors to his lieutenants in the various cities in which the Munsey papers are located. He appointed Robert H. Davis toastmaster, the latter introducing the various speakers in a series of sallies replete with a dry humor which was particularly taking. Chairman Trego told the many non-participants present just what a reliability contest means and how it is conducted. Frank Presbrey, who was introduced as the author of the famous Kansas big corn story, was introduced as "the greatest liar of the century," and proceeded to make good, finishing up by congratulating the promoters on evolving a scheme which gathered together such a fine-looking body of men.

At 8.05 o'clock the Philadelphia *Evening Times*, containing an account of the day's run, was distributed to the banqueters, which brought forth much sarcasm from Toastmaster Davis anent Quaker City slowness. Editor Taft, of the Philadelphia paper, successfully defended his town against the aspersions of the discomfited Gothamite and publicly introduced Drivers Aiken, Matson and Knipper to Mr. Munsey.

E. D. Shaw, editor of the Washington *Times*, called attention to the fact that in 1893 Mr. Munsey had written of the future of the automobile in a vein which, in the light of present-day conditions, stamped him as a prophet. Arthur Newmyer, also of the Washington *Times*, and chief checker of the run, told of the numerous entertainments furnished the tourists en route. Colonel McLane, of Canada, a personal friend of Mr. Munsey, told how the latter "got his nerve" by fast driving during a recent tour in France.

Mr. Munsey wanted it particularly understood that the idea in promoting the present tour was not so much for its advertising value as for its virtue as a journalistic "stunt." He promised a repetition of the run next year and finished by complimenting the participants on their endurance and good humor in the face of elemental conditions that were little short of disheartening.

The "S" Turn Near Laurel, Long Island, that Presented Some Difficulties Even to Experienced Drivers.

CHEVROLET DRIVES 70 M. P. H. IN LONG ISLAND DERBY

RIVERHEAD, L. I., Sept. 29—The Long Island Stock Chassis Derby is now history, marred by one fatality and noted for its exceptional demonstration of speed. Louis Chevrolet in his victory in class 4 with the 30-horsepower Buick, traveled at a speed which was close to 70 miles per hour, this being the greatest sustained flight ever accomplished in an American road race.

The event for big cars was taken by Ralph DePalma, a driver of established reputation, whose Fiat outlasted its opponent and covered the 227.5 miles at a pace of 63.35 miles per hour. It was during this session of the race that Herb Lytle, a driver of long experience besprinkled with numerous close calls, skidded and overturned at a bend in the road, seriously injuring himself, while his mechanic died as a result of the unfortunate affair, very shortly after the accident happened.

Unquestioned interest existed in class 5—$851 to $1,250—which resulted in a double victory for the new Maxwell Q. The winning car went the 91 miles in 53.9 M.P.H., with the second Maxwell not far behind.

Despite the ideal fall weather, the attendance was small, though there was splendid racing. Fifty per cent. of the profit was to have been divided among the winning drivers, who were represented by George Robertson. Unfortunately, there will be a deficit instead of a profit, and, of course, all that the drivers will get will be the cups won in their respective classes.

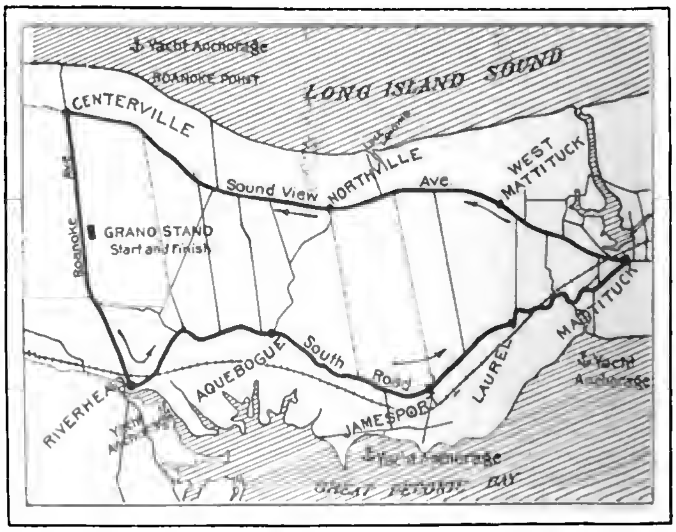
The timing was taken care of by A. P. Warner's time-recording instrument, presided over by the inventor himself, assisted by the members of the New York Timers' Club.

Suffolk County, which adjoins Nassau County, scene of the Vanderbilt Cup races, wanted an automobile contest, and so indefatigable Senator Morgan was prevailed upon to assume the burden of its conduct. A 22¾-mile triangular course was laid out with two 9-mile stretches, and the grand stand located a couple of miles from Riverhead, which had been the storm center of the miniature Vanderbilt. Proceeding thence easterly along the shore of Great Peconic Bay to Mattituck, a sharp turn and a westerly road led along the shore of Long Island Sound to Centerville. From there a three-mile straightaway led past the grand stand, located midway between Riverhead and Centerville.

Five classes, arranged according to price and not piston displacement, were provided for, the sum total of starters being 15, divided as follows:

	Car	Driver
$4,001 and over......	Rainier	Disbrow
	Mercedes	Armstrong
	Fiat	DePalma
$3,001 to $4,000.......	Rainier	Lund
	American	Hughes
$2,001 to $3,000.......	Palmer & Singer.......	Lescault
$1,251 to $2,000.......	Sharp Arrow...........	Sharp
	Chalmers-Detroit	Droge
	Buick	Chevrolet
	Buick	Burman
$851 to $1,250.......	Maxwell	See
	Buick	Finch
	Maxwell	Doorley
	Maxwell	Costello
	Overland	Riess

It was a scantily covered stand that saw the start at 9 o'clock, though the parking place contained several hundred cars. Around



Map of Long Island Derby Course—22.75 Miles the course the spectators numbered thousands, to watch the passing of the speed craft without expense.

Lund's Rainier was protested in the matter of price in Class 2, and while the case will go to the A.A.A. contest board, the car was transferred to Class 1, and its time taken for both 10 and 8 laps.

It was anticipated that the big Mercedes, once the property of W. K. Vanderbilt, Jr., and now owned by candy-maker Loft, would supply the most plentiful speed, which it did with an opening round in 19:01, a race approaching 65 miles per hour. De Palma's Fiat did the circuit in 22:12. Anxiously Lytle was waited for, but came not, and the meager report finally arrived that the Apperson had met with disaster and turned over near Mattituck. Disheartening news ultimately came that both Lytle and Bates were badly injured, the latter fatally. A skid from the partially-crowned road at a bend while traveling at top speed, was the only explanation of the accident which included colliding with a telephone pole. Physicians were quickly summoned but Bates was beyond aid, though an examination of Lytle resulted in the report that his recovery was almost certain.

During its second round the big Mercedes had an innings of tire troubles which made frequent replacement necessary and gave the lead temporarily to Disbrow's Rainier. In the third lap, the German-built car came back with 18:49, which made a lead of over a minute on De Palma's Fiat. In the next whirl, the Italian closed up some of the gap, the two being only 23 seconds apart. In the fifth lap the Mercedes had engine difficulty which caused the passing by the Fiat.

News of the Apperson catastrophe reached the grand stand just as the ailing Mercedes drew alongside its pit. Mrs. George W. Loft had been much upset by the information, and making her way to the car directed that it be withdrawn at once. Barring unusual trouble, this left the Fiat apparently a sure-enough winner, for the others were a long ways behind.

While the big cars were going the greatest distance, the smaller classes were having some interesting fights. In Class 4 the Buick of Chevrolet evolved as the startling winner at a pace which averaged 70 miles per hour. Burman, with another Buick, figured as the runner-up, though only 10 seconds behind.

In Class 2, Lescault's Palmer & Singer proved a winner practically unopposed, its opponent, the American driven by Hughes failing to make much of a fight, owing to cooling difficulties.

The only contestant in Class 3, W. H. Sharp's Arrow, driven by its maker, supplied an average of 63.6 miles per hour, which was an exceptionally good performance.

In Class 5, the littlest fellows of the race, the two Maxwells. captured the first two places, Arthur See's Model Q going the route in 53.9 miles per hour. J. Finch's Buick ran third.

SUMMARY OF RESULTS IN LONG ISLAND STOCK CHASSIS DERBY, RIVERHEAD, L. I., SEPT 29, 1909

No.	Car	H.P.	Driver	1	2	3	4	5	6	7	8	9	Finish
	CLASS 1—$4,001 AND OVER—10 LAPS—227.5 MILES												
3	**Fiat**	45	Ralph De Palma	22:12	46:00	67:12	89:26	110:49	132:39	153:35	176:10	197:16	218:35.6 avge.. 62.35 m.p.h.

SOME NEW BOOKS FOR AUTOMOBILISTS

"Italian Highways and Byways from a Motor Car"—This pleasantly rambling narrative of a rambling automobile tour through Italy comes from the pen of Francis Miltoun, whose work may often be found in these pages. Although the tour and its itinerary form the framework of the story, let it not be imagined that the author has bound himself to a dry recital of incidents and route book details. Far from it; he philosophizes at length, and most enjoyably, on the inner nature of the Italian, his liking for red wine, macaroni and *ravioli,* his roads, inns, and bath tubs. Of the conventional traveler's diary, nothing at all; Mr. Miltoun would far rather discover one new castle than "do" a hundred listed in Baedecker, and he pokes mild fun at the hurried and "conducted" tourist, be he English, German, or American. Also he delights in unearthing bits of medieval history, tales of a robber baron or a stolen bride, which give a romantic charm to each new-found castle.

The book itself is worthy of its contents; strikingly printed on rough-edged, cream-tinted paper, it is illustrated with a multitude of drawings and water colors by Blanche McManus. There are no less than eight full-page colored plates, and any number of full pages in half-tone, besides maps and plans. L. C. Page & Co., of Boston, the publishers, have good reason to be proud of their part of the work.

"Heures du Grand Nord"—The name of Georges Dupuy is familiar to every reader of THE AUTOMOBILE, and the word that he has written a book on his experiences in the United States makes one look forward to more of his delightfully original comment on us and our ways, that happy mingling of good-natured criticism and whole-hearted approbation, which really enables us "to see ourselves as others see us." Unlike the average European who spends a week in this country, and then, returning home, writes a volume of "impressions" or "thoughts" ridiculous in their immaturity and ignorance, M. Dupuy is thoroughly familiar with his subject. He has spent much time among us, is acquainted with our manners and customs, and. if not always approving, at least is sympathetic.

The subject-matter of the volume, to be more explicit, is taken from M. Dupuy's experiences in Canada and Alaska, especially in the gold mining regions. His little stories are related with a naiveté of style, a simple and unaffected realism, which would do credit to many a more famous author. Incidentally, M. Dupuy takes a fling at our roads. One of them he mistook for a drainage canal. The volume contains 280 pages of witty and entertaining anecdote, illustrated moreover with two full-page drawings by Blanche McManus. The publisher is the Société d'Imprimerie, 71, rue de Rennes, Paris.

Some Forest Giants That Are Kin to the California Redwoods

TO the automobilist, the Island of Vancouver offers the most fascinating of all countries for his favorite recreation. There are three basic necessities in automobiling, without which the sport cannot be enjoyed to its fullest. These may be set down in order of importance as follows: good roads, good weather, and beautiful scenery. The question of accommodations is also one of importance, but considering the ability of the average motor car in the way of carrying capacity, it is not of such vital importance as the first three named.

Vancouver Island has the best roads on the American continent. They may possibly be surpassed in mere highway excellence, as roadbeds, in the Old World, but they more than make up for any possible lacking in this respect by the magnificence, variety, and beauty of the scenery along and around them. They are natural boulevards, and the equability of the climate renders the keeping of them in perfect repair a matter of comparatively little labor. New roads are being opened up in a number of different directions, penetrating hitherto untouched cloistered spaces of exquisite loveliness, and it is nothing more than truth to say, that Vancouver Island has in its various highways and grandeur of scenery, the very Mecca of motor car enthusiasts. The roads through the island, starting from Victoria, are almost numberless in extent and variety. The Ocean Beach drive, taking the sightseer to the docks along Dallas road, through the famous Beacon Hill park, and along the beach to Oak bay, and from there back to Victoria by way of Oak bay and Rockland avenue, is a run unequaled in North America. A view of the Olympic range across the Straits of Juan de Fuca, as seen from the crest of Beacon Hill park, is one that, once seen, will never be forgotten. The blue vastness of the straits, dotted here and there by sails, or streaked with the smoke from passing smokestacks, backed by the towering steeps of snow-clad mountains, is a picture of which there is no double in the world. The Orchard drive is another incomparably beautiful drive, taking the traveler through a section of country that is fast being turned into splendid fruit farms. Here and there, the sea and glimpses of mountains add variety to the journey, while the golden blaze of Scotch broom, garlanding the hills, seem like so many wreathes of sunshine, clustering thickly in their yellow splendor.

To Douglas mountain and Cordova bay is another splendid drive, as is also the famous run to Esquimalt, where the navy dry docks are located, and close by the fortifications of Fort Macauley. To North Saanich, Saanichton, and Sidney, is another splendid drive, taking the visitor through a magnificent stretch of agricultural country, with the sea close at hand. To Albert Head by way of the Gorge road, Colwood, Happy Valley, and Metchosin, is another favorite run from Victoria, and here fruit farms and forests, ocean and valley, make a panorama of never-ending beauty. To Goldstream is another magnificent drive. Shawnigan lake, Duncan, Cowichan lake and bay, Maple bay, and other places can be reached on perfect automobile roads, with many excellent hotels and stopping places all along the route. The city of Nanaimo, with its herring and salmon fisheries, its coal and mining industries, is another point of interest very much frequented by the automobiling travelers, and all along and through these latter points, fishing, shooting and sea bathing, can be enjoyed. For a more extended trip, the run to Alberni, by way of Nanaimo, will take the automobile traveler into a country whose beauties far surpass in reality the world famous Alpine scenery of Switzerland. Sproat Lake has been termed the "Lake Lucerne of Vancouver Island," being similar to that lake in shape, but far outstripping it in natural beauty. Grand Central lake, also in the neighborhood of Alberni, is another magnificent sheet of water, and both these lakes are in the close vicinity of some of the most wonderful timber in the world. All through the Alberni district the fishing is superb, and the roads are the finest.

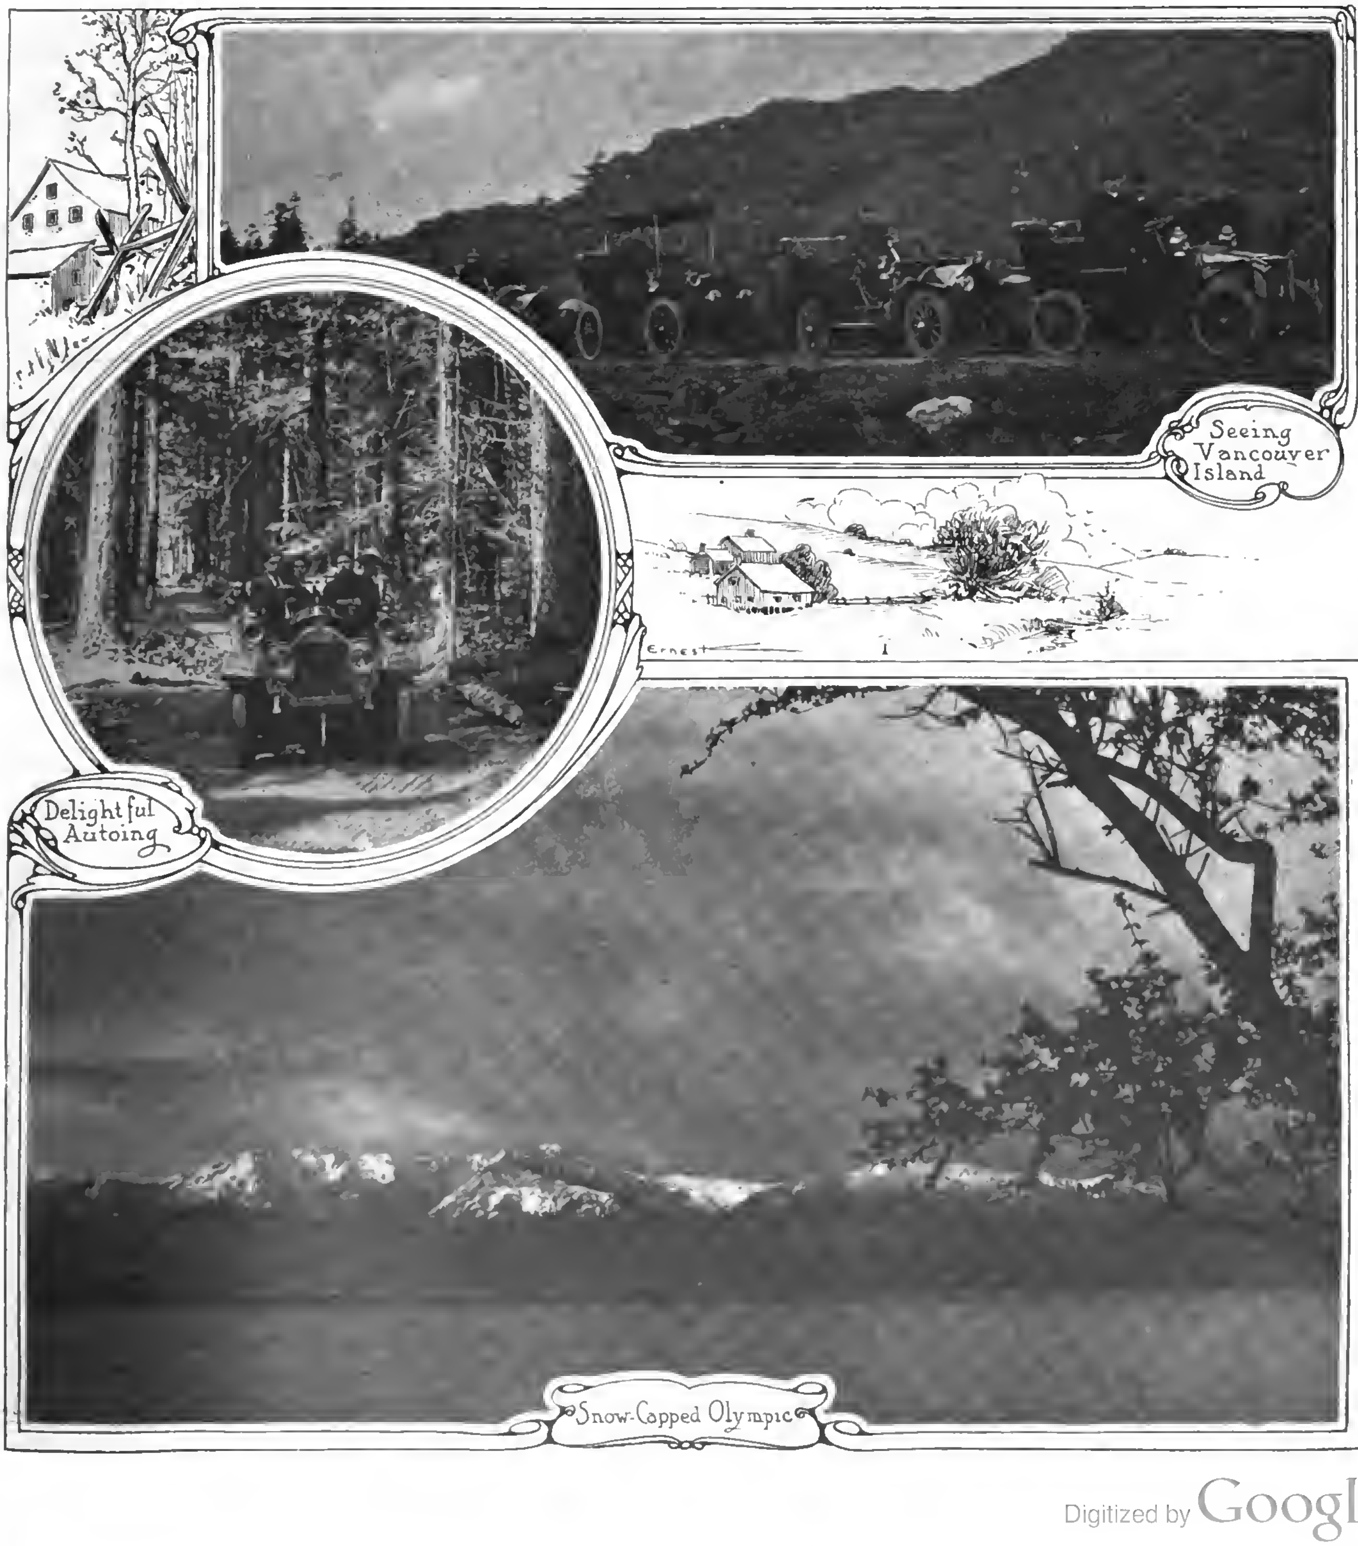
Weather and Scenery All That Can Be Desired

One of the particularly attractive features to automobiling in Vancouver Island is the serenity of the weather. From June 1 to October, the traveler can be almost assured of clear skies and sunshine, while at the same time the nights are cool and pleasant. All through these different districts, also, the traveler will come across the Indian reservations, containing the remainder of the tribes who once dominated the island, and the picturesqueness of their surroundings, and the interest of their condition, now almost semi-civilized, make up one of the unique features of a tour. To attempt to describe the scenic grandeur of Vancouver Island, would require the brush of a Doré, and the pen of a Shakespeare. No possible combination of modern talents, and even genius, can give it its dues. A constant change from seashore to forest, from mountain lake to rushing river, from sparkling streams to deepest depths of woodland silences, from stony wastes to flower crowned summits, all make a kaleidoscopic splendor, which must be seen to be even faintly appreciated. The shining colors of the cock pheasant may be seen strutting proudly through some of the lowland meadows, while the grey reticence of a grouse's wings occasionally flash through the road-side spaces in the timber recesses. Deer crash through the fir and cedar underbrush, while streams and lakes are alive with leaping trout.

The traveler coming from the United States can bring his own car across, provided it has been used by him in the States, without duty, and he will find himself most richly repaid by a trip around and through the island. The scenery of Vancouver Island, in its sublimity and endless surprises, cannot be equalled, much less excelled, anywhere. It may be true that some particular points in Europe may hold more of historic interest, but for nature undefiled, in its sternest and in its most alluring moods, there is nothing comparable from a scenic standpoint to the wonders found here. The traveler-autoist will be able to purchase supplies and all necessary conveniences for a trip, whether long or short, in the various towns and districts of the island, and he will find good accommodations at very reasonable prices, wherever he chooses to travel. There are some portions of the island, of course, where it is absolutely impossible to penetrate with an automobile. Impossible, indeed, to penetrate save on foot, and there are portions of the island now, where neither the mocassined foot of the Indian, nor the hobnailed heel of the trapper or prospector, has ever been set.

It is this very wildness, this essence of the primitive, this pristine glory, which even yet halos those portions of the country accessible to an automobile, which constitute one of the chief charms of a trip through the island. Here may be seen deep fiords, through which the early voyagers sailed. Here still may be seen the carved prows of aboriginal canoes, cutting the water to the strokes of the Indian's paddle. Here the deer and bear roam, the wolf and panther couch and forage, and here the roar of wild fowl wings makes thunder in the Spring dawns and sunsets. This is indeed a land to be visited of all men, by those who can afford the time and expense of an auto trip. The roads, the weather, the accommodations, are all that could be desired. The scenery, something practically indescribable in its extent, variety, and beauty. It is the automobile enthusiasts' greatest opportunity; the threshold of the Pacific, the last and greatest West that has unfolded itself to the world.

With the number of people attracted to the Alaska-Yukon-Pacific exposition, abbreviated A-Y-P, at Seattle, and many of them



Seeing Vancouver Island

Delightful Autoing

Snow-Capped Olympic

automobilists, who have taken their cars along, this description of the natural beauties and beautiful drives on Vancouver Island will come with peculiar appropriateness. To get to the Island from Seattle is not a very long ride on the boats, and even to one disliking the water trip, the 85-mile ride on Elliott Bay and Admiralty Inlet, with the views of the Northwest corner of our great and glorious country, is well worth while.

To make the trip, there is a sail of ten miles on the bay before the Inlet is reached, after which the remaining 75 miles is in a course due northwest to Victoria. This takes a person past Whidbey's, Smith's, and the San Juan Islands on the right or to the northeast, while of the other side, numerous peninsulas of equal natural grandeur are passed by. These latter include the little known Pöint No Point, Port Madison, Port Ludlow, and others, as well as the better known, Port Townsend.

This trip brings one to Victoria, from where Esquimault, previously mentioned as the terminus of a famous drive, and as the location of the Naval dry docks, is but a short ten miles. For those preferring the water, continuing on to the left, but with the direction changed to due west, brings one through the Straight of Juan De Fuca, ultimately to the ocean. Bearing instead to the right and still northwest, after skirting the San Juan group of islands, brings one through the Straight of Georgia to the same end, the blue waters of the Pacific.

AERO SCHOOL FOR YOUNG GERMANS

Berlin, Sept. 10—Germany's first aeronautic school will come into existence October 1, at Friedrichshafen, the working place of Count Zeppelin. Eight pupils will be accepted for the first year, and must sign for a two-year course. All applicants must be under eighteen years of age.

Close to Nature's Heart

Real Road in Wilds

On way to Nanaimo

St. Louis Secures 1910 Good Roads Convention

CLEVELAND, Sept. 24—Seven cities sought more or less assiduously the distinction of being the gathering place for the "Third Annual Good Roads Convention" to be conducted by the American Automobile Association and essentially aided by the National Grange, the American Roadmakers' Association, and the several organizations of automobile manufacturers.

St. Louis won out, and so in the fall of 1910 the good roads workers will participate in a highways fest which the Mound Cityites assert will establish a standard that will require considerable effort to surpass in future events of like character. An inning of talk by men of experience and some demonstrating of up-to-date methods of construction are considered to be just what are needed to show the Missourians how badly they are in the rearguard of commonwealths. Sam D. Capen, of the Automobile Club of St. Louis, had much to do with the selection of St. Louis, his material including an effective orator in Mr. Cannon, an invitation from the Business Men's League, a letter from Mayor Kriesmann, and a telegram from Governor Hadley. That this formidable array of material was effective is best shown in the final result, St. Louis winning out.

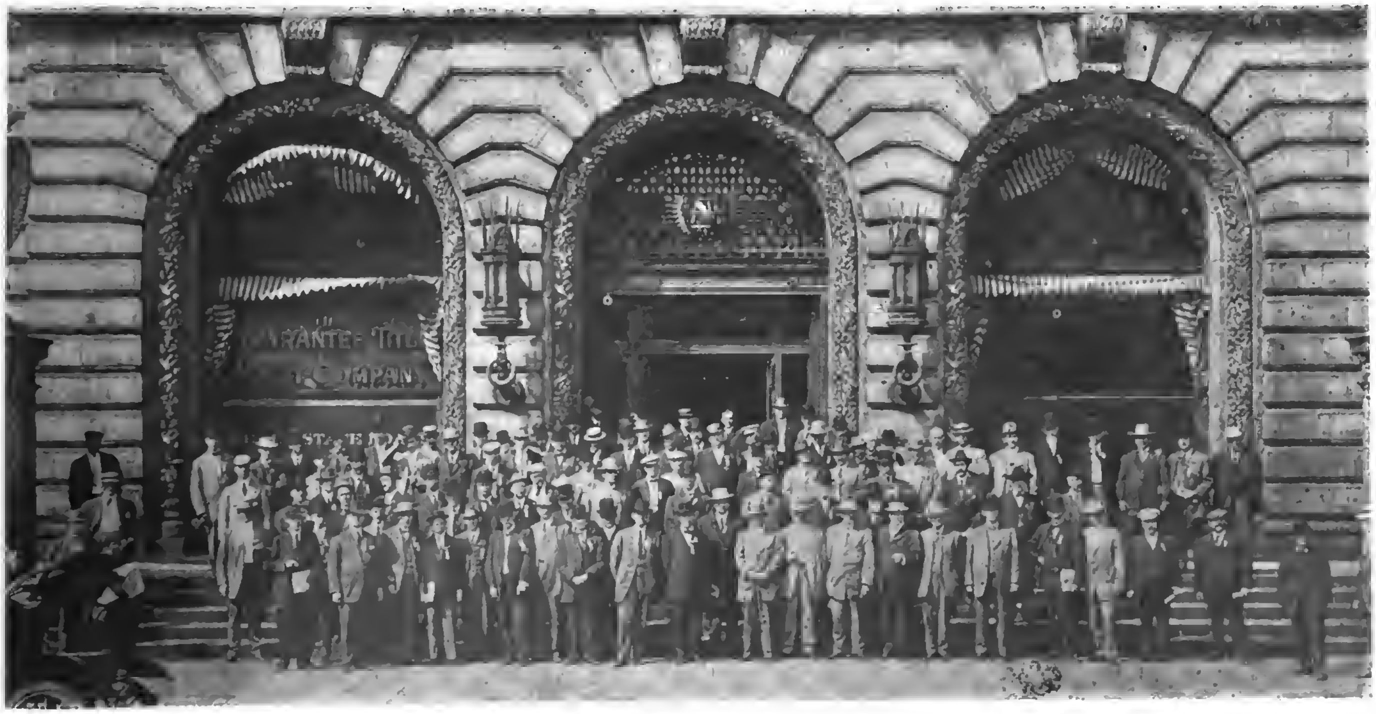
Forty-one States had representatives in the Cleveland convention, which, while less in numbers than the Buffalo gathering, expressed more forcibly the keynote of progress in roads construction. It so happened that Cuyahoga county had in process of building some 165 miles of pavement of a considerable variety, which meant that delegates had an opportunity of learning first-hand of their relative worth and cost. Vitrified brick predominates, even in the country districts, owing, undoubtedly, to the presence of material in plenty for brick-making, in the immediate neighborhood, so as to be quickly available. This point carried weight.

In the report of the committee on resolutions were contained two timely matters, one referring to the need of greater caution in the use of the highways, and the other to the proper marking of all roads and post offices. The following is the resolution which referred to the use of the roads:

RESOLVED, That it is the unanimous sentiment of the representatives of the National Grange, the American Road Makers' Association and the American Automobile Association, in National Convention assembled, that the enormous increase of travel upon the public highways requires that drivers or operators of vehicles shall observe with added care the rights of all users of the roads; and automobilists particularly, because of the greater possible speed of motor cars, are requested to exercise extreme caution and kindly consideration in aiding the general public to become accustomed to this method of transportation. Furthermore, the many law-abiding automobilists are asked to aid in the enforcement of just regulations and assist in the apprehension of the comparatively few offenders who are deaf to persuasion and persistent in disregarding the rights of their fellow occupants of the roads.

The indifferent marking of the roads and the invariable failure to include the name of the town on its post office sign, brought forth the following:

RESOLVED, That this convention calls upon township, county and State officials, where empowered, to see that all roads are properly marked; and, furthermore, where such authority does not exist, to obtain same at the earliest possible moment, in order that this most important work may be carried out with uniformity. Incidental to this plan should come the placing of the name of each village, town or city on its Post Office, for modern travel now embraces a growing use of the public highways, and as a sequence the enlarging of attendant conveniences.



Assembled Group of Delegates to the Second Annual National Good Roads Convention at Cleveland

Secretary James T. Drought and the Wisconsin Delegation

Of course the convention tendered its unanimous thanks to the Cleveland Automobile Club for its aid in making the convention a success, and the plan of Delegate Johnson, of Oklahoma, furthering the good roads cause in that State, was given the stamp of approval. Again was the Currier good roads bill, now pending in Congress and backed by the National Grange, given unqualified endorsement.

In preparation for the 1910 convention, a committee was selected composed of the following or their successors as designated by the organizations which they represent:

Geo. C. Diehl, Buffalo, N. Y., Chairman A. A. A. Good Roads Board.

N. J. Bachelder, Concord, N. H., Master of the National Grange.

Logan Waller Page, Director United States Office of Public Roads, Washington, D. C.

James H. MacDonald, Hartford, Conn., President American Road Makers' Association.

S. D. Waldon, Detroit, Mich., President National Association of Automobile Manufacturers.

Coker F. Clarkson, New York, Association of Licensed Automobile Manufacturers.

Alfred Reeves, New York, General Manager American Motor Car Manufacturers' Association.

Chas. Thaddeus Terry, New York, Chairman Legislative Board, American Automobile Association.

Ralph W. Smith, President Colorado State Automobile Association.

Sam D. Capen, President Automobile Club of St. Louis.

Jas. T. Drought, Milwaukee, Secretary Wisconsin State Auto Association.

Louis R. Speare, Boston, Mass., President American Automobile Association.

Fred'k H. Elliott, New York, Secretary American Automobile Association.

The committee was given power to add to its own members, to the extent of five, the representatives of any other bodies which might be interested in the good roads movement.

The inclement weather of the concluding day made necessary an abandonment of the boat-ride on Lake Erie, and the theatrical entertainment in the evening wound up the convention, though many had been obliged to turn homeward on the afternoon trains. The next time it would appear the best plan to have the entertaining festivities more or less intermingled with the business session.

ROAD SITUATION IN U. S. COMPARED WITH FOREIGN COUNTRIES*

By LOGAN WALLER PAGE, Director U. S. Office of Public Roads.

THE present road situation in the United States may be briefly summed up as follows: In mileage, we have the most tremendous system of roads which any country has ever possessed since the world began. According to a careful road census, the length of all of our roads amounts to 2,155,000 miles. The most liberal estimate of our annual expenditure on these roads, both in money and labor, was a fraction over $79,000,000 in 1904, or about $1.05 per capita. At the same rate, this would be an expenditure of about $90,000,000 a year at the present time. England, with only 150,000 miles of road, spends about $80,000,000 a year, or about fourteen times as much per mile.

According to our road census, we have less than 40,000 miles of stone surfaced road, or about 2 per cent. of the total mileage; we have 108,000 miles of gravel roads or about 5 per cent. of the total mileage. Small as our annual expenditure for roads has been, it has aggregated, during the 30-year period from 1870 to 1900 a total of upwards of $1,800,000. We may, therefore, say that road building in the United States is, considering area, population, and wealth, at the same point at which it stood thirty years ago, and the seventeen hundred and odd million dollars have produced few appreciable results.

When we turn to the subject of road administration in the United States, we find that about half of the states are operating under practically the same road laws as prevailed in England when America was a colony. This system of road administration provides for the payment of road taxes partly in labor, and localizes the work to an extreme degree, by placing in authority the district or township road overseers, or road supervisors, no requirement being made to insure skill or knowledge of road building on the part of these petty officials. With few exceptions no system of accounting is in force so that an intelligent idea may be obtained as to the disposition of the road tax, and no definite lines of authority are established such as would guarantee the wise and equitable conduct of the work.

This is the system which prevailed in all the states until less than twenty years ago. It is, therefore, easily understood why, at the present time, the concrete results in the matter of road building are so few, are confined to a comparatively recent period, and are located in those States which have broken away from the inadequate and ineffective system which I have just described. It can also be understood why, at the present time, road work in those States which have clung to the old methods and the old system is conducted in a wasteful, intermittent and wholly ineffective manner, productive of no good results.

Road administration has either been placed on a sound and practical basis, or steps taken in that direction in about half of the States of the Union, comprising the New England States, New York, Pennsylvania, New Jersey, Delaware, Maryland, Virginia, West Virginia, Ohio, Michigan, Illinois, Wisconsin, Minnesota, Missouri, Kansas, California and Washington. These States have adopted in principle or practice, or both, the system of centralizing under a State highway department the conduct of all or part of the road work of the State, thereby securing uniformity in methods, economy in administration, and skill in supervision. In some of the State highway departments the work is educational and investigative, with a view to ultimately giving these departments administrative powers. Some of the States, notably Kansas, Missouri and West Virginia, have provided for skilled supervision in the counties, through the appointment of county highway engineers. In most of these States appropriations have been made from the State treasuries, or the aid of the State convict force has been given toward carrying on road work throughout the various counties.

It is not possible in a short paper to enter into a discussion of the various systems of State aid in effect in this country. Suffice it to say that the principle of State aid and supervision constitutes the germ of the only road administration which has proven successful in other countries.

This movement is gaining headway at a very rapid rate, and when we consider that it has been little more than a decade and a half since its inception, the fact that half of the States have adopted it in principle and have actually expended from State treasuries considerably over $56,000,000, we may well feel encouraged for the future of road building in this country.

Effectiveness of French System

The striking feature of the French road system is the skilled supervision in every grade of road work and in every unit of the administrative organization. The basis of the system is the school of roads and bridges, one of the finest technical schools in the world, maintained at the expense of the national government. In this school are trained the highway engineers to whom are entrusted the building and maintenance of the roads of France. The course of study lasts three years and the instruction is free.

At the head of the administrative organization is an Inspector-General of bridges and highways, under whom are chief engineers

*Read at the Second Annual National Good Roads Convention, Cleveland, Sept. 23, 1909.

in charge of the road work of single departments and communes. Single arrondissements are under the direction of ordinary engineers and under engineers, the latter being equivalent in rank to non-commissioned officers in the army. The sub-divisions are under the direction of principal conductors and ordinary conductors. Next in line come the foremen of construction gangs, the clerks employed at headquarters, and finally the cantonniers or patrolmen, each having from four to seven kilometers of highway under his immediate supervision.

This great administrative machine working in complete harmony with definite lines of responsibility clearly established, accomplishes results with the precision and regularity of a great clock ticking off the seconds of time. Probably the most important unit in this great army of workers is the cantonnier or patrolman who has charge of a single section of the road. He keeps the ditches open, carefully fills holes and ruts with broken stone, removes dust and deposits of sand and earth after heavy rains, trims the trees and bushes, and when ordinary work is impossible he breaks stone and transports it to points where it is likely to be needed. He brings all matters requiring attention to the notice of his chief. Each cantonnier carries a little book in which the chief cantonnier notes his instructions and checks up the work accomplished. The conductors go over the line at regular intervals and direct the chief cantonniers, and all reports are transmitted to the central authorities, so that any day or any hour the exact condition of every foot of road throughout France may be ascertained. Every year the conductors prepare estimates of necessary expense for the next year, under three heads, namely, Maintenance, Heavy Repairs and New Work, and the parliamentary appropriations are based upon these careful calculations.

There are in France at the present time 23,656 miles of national routes which cost $303,975,000 to build. There are 316,898 miles of local highways built at a cost of $308,800,000, of which the State furnished $81,060,000 and the interested localities $227,740,000. The roads of France are classified into five classes: National routes, traversing the various departments and connecting important centers of population; department routes connecting the important centers of a single department and bisecting the national routes; highways of grand communication, little less important than the previous class; highways of public interest traversing a single canton and connecting remote villages and groups of houses with the more important roads.

How Work Is Done in England

There are at the present time 149,759 miles of road in England, on which the annual expenditure for the year 1905 to 1906 amounted to $78,059,000. It is, therefore, evident that the annual expenditure per mile of road amounts to about $520. In view of the fact that most of the principal roads of England have already been constructed, this large annual expenditure would appear to be devoted in a large measure to maintenance. It would seem that a system which required an annual outlay of $520 per mile for the entire mileage must be ineffective and costly. The explanation of this is found perhaps in the fact that in England the maintenance of the public highways devolves entirely on local authorities, these numbering about 1,900. Jurisdiction over the roads is vested in, first, the county boroughs; second, the county councils; third, the urban district councils; fourth, the rural district councils. The county boroughs are certain large towns which hold charters from the Crown entitling them to the privilege of self-government. In these the maintenance of the highways devolves entirely upon the borough or town council. In counties the maintenance of highways devolves upon urban councils in the urban districts and rural councils in the rural districts. The only exception to the control of the urban and rural district councils is in the case of main roads which are highways between great towns, and the maintenance of these roads devolves upon the county councils.

Revenues are provided by district taxes except for the main roads, for the maintenance of which the county levy is made. The national government aids in the maintenance of the highways by a contribution proportioned to the sum raised by the imperial taxation levied in the different areas.

As to skilled supervision, it may be said that no qualifications are required by law to be possessed by the men in charge of road building and maintenance, but it is the general practice in the important districts to appoint experienced highway engineers for this work. The English system lacks strong central control in each county, there being four different classes of government units, namely, the county boroughs, the urban districts, the rural districts and rural parishes. While the county council exercises some control over the rural districts and the rural parishes, they exercise none over the other two units.

Germany Has the State Plan

Germany is a federation of states, and it follows that road administration is conducted separately by each State of the Empire. The imperial government exercises very little control over the highways, and does not in any way contribute to the expense of their construction and maintenance. The kingdom of Saxony may be taken as a representative State of the German Empire. In Saxony the highways are divided into state roads, country roads and private ways. The state roads comprise those which have been built by the State and are maintained by the State. The county roads are generally termed "communicating roads," and are built and maintained at the expense of the parishes through whose territory they lead.

Richardson, New York; MacDonald, Connecticut; Bonifield, Ohio

A striking feature of the Saxon road system is the practice of planting fruit trees along the roads, the fruit yielding a considerable revenue. About $40,000 a year is obtained from the fruit grown along State roads, while the amount obtained from the country roads represents a much larger sum.

The State roads are cared for by a commission of engineers. The kingdom is divided into seventeen road districts, in each of which there is a road inspector. Under these inspectors are road masters, who are employed constantly throughout the year. Each road master has about thirty-seven miles of road under his direction and a road force of about fifteen men, each man caring for two and a half miles of road.

In the case of the minor roads the direct responsibility is borne by the authorities of the county. They levy the cost of maintenance and collect the revenues. The communities engage the road employees for the continued care of the highways. The technical supervision, however, is exercised by the road masters of the State force. Strict provisions are made requiring skill and special knowledge before road officials are appointed.

Switzerland Has a Local Supervision

The road system of Switzerland is local in character, the various cantons having jurisdiction over the roads within their respective borders. The roads are classified into State roads, built and maintained at the expense of the respective cantons; community roads, built and maintained by the communities, and side, or auxiliary roads, connecting main lines of State or community roads.

Each canton has at the head of its road system an engineer with capable assistants. In the canton of St. Gall, which may be taken as representative, there are under the control of the engineers five inspectors, or road masters, who are assigned to certain districts in the canton. The engineers and their assistants must have an academic education, and possess a diploma from the Polytechnic Institute, while the road masters are required to have a good technical education.

Summing Up the Various Plans

It is apparent from the foregoing that while the units of administration in European countries range all the way from the localism of England to the highly centralized system of France, through varying degrees, skilled supervision is provided by all of the systems, as well as an ample cash revenue sufficient to enable the engineers to carry out adequately their plans for improvement and maintenance. England is the most striking example of extreme localization, and it is a significant fact that England is also the most striking example of lack of uniformity in road work and of excessive expenditure in proportion to mileage. It is also significant that the most perfect road system, conceded to be such by all authorities on highway construction, is that France admittedly has the most highly centralized of all road systems. France, with a total mileage of about 2 1-3 times that of England, expends about the same amount annually for maintenance. Certainly the inference must be plain that centralizing makes for economy and efficiency in the administration of the public roads.

I desire to comment particularly upon what I consider to be the most important point which should engage the attention of American road builders and legislators at the present time, and that is road maintenance. In the years that have past by far the largest portion of our annual expenditures has been for maintenance of our unimproved roads; a maintenance which may justly be considered a mockery, for it has been a maintenance of the roads in almost their primitive condition. Now that we are actually building roads which compare with the best in Europe, it is of the greatest importance that we make provision for safeguarding and maintaining these roads built at so great an expense.

In a careful study of the highway laws which have been enacted within the past fifteen years, I find almost no provision for the maintenance of the roads, although large sums are authorized for construction. The erroneous impression generally prevails that when a so-called permanent road is constructed it is there for all time, and the expense has practically all been met. I have investigated the cost of maintaining roads in the leading European countries, and the figures may almost be said to be a revelation. In 1901 England and Wales maintained 26,589 miles of main roads at a cost of $370.34 per mile. In 1907 England and Wales maintained 27,566 miles of main roads at a cost of $446.74 per mile, or, in six years, the cost of maintenance has increased $76.10 per mile—an increase of over 20 per cent. In France the increase in cost of maintenance of the national roads has been about 5 per cent in the same period. The cost of maintaining main and suburban roads in England and Wales in 1905 and 1906 was $440.47 per mile. In France the cost of maintaining all roads during 1904 was $243.33 per mile. While these last figures are not strictly comparable, one being for 1904 and the other for 1905, yet the mere fact of one year's difference in time fails to explain the difference of $197.14 per mile in cost of maintenance—the natural inference being in favor of superiority of the France system.

In Germany in 1906 the average cost of road maintenance was $214.13 per mile. In Belgium the annual cost of maintaining the provincial roads is $277 per mile.

These figures express most forcibly two facts: First, that even the best of improved highways are not self-sustaining; second, that the cost of maintenance varies tremendously with the degree of centralization of the administrative organization which has the roads in charge. France with its most highly centralized organization is maintaining her roads at about 54 per cent of what it costs England and Wales with a very local and loosely centralized organization. Furthermore, the alarming increase in the cost of maintenance has been far more rapid in the countries with local and poorly organized systems of highway administration. We have just seen that while the rate of increase in maintenance from 1901 to 1907 in England and Wales was over 20 per cent, it was only about 5 per cent during the corresponding period in France. In England the maintenance is often intermittent and varies: in France the maintenance is continuous and highly specialized.

Many of our States have spent and are spending large sums of money on their highways with but little thought or provision for maintenance. This, if the experience of European countries is of any value, must prove disastrous in two ways: First, granting that the roads constructed at so great cost will not be allowed to go entirely to ruin, the cost of maintenance will be higher the more local and loosely centralized the organization for maintenance; and second, systems of intermittent maintenance are sure to increase in cost from year to year as they have in Europe. It is high time that our legislatures take note of these facts and provide ways and means so that our roads once constructed can be maintained efficiently and economically and not allowed to go to ruin, and that exorbitant sums need not be expended on fruitless efforts to maintain them unsystematically and in an unscientific manner.

It must also be evident from a study of expenditures in Europe that our road revenues are entirely inadequate. While $80,000,000 seems a large sum, it is only about $38 per mile to meet all new construction, bridge building and every class of maintenance.

We need, and must have, more money for roads, definite provision for maintenance, a system of continuous repair and a centralized, skilled supervision.

INFLUENCE OF AUTO ON "BACK TO THE FARM MOVEMENT"

By HAYDON EAMES, General Manager Studebaker Automobile Company.

J. J. HILL'S address before the meeting of the Bankers' Association of Chicago, is most refreshing, and gives the ordinary business man considerably more confidence in the mental grasp of those who control our financial affairs.

There is one point, however, in regard to which Mr. Hill seems to be misinformed: the favorable influence of the automobile upon the very conditions which he would like to bring about—increase of agricultural as compared with urban population.

It looks as though the vast affairs with which he is concerned have compelled him to view the farmer collectively rather than individually, and he seems to be correspondingly unfamiliar with the change the last six or seven years, and the advent of the automobile, has made in the details of the farmer's life. Nor does he seem to recognize the large part which the automobile has, and can be made to play in justifying the extension of his own railroads and in the preliminary work of opening up new territory with that ultimate object in view.

We wonder if he recognizes the extent to which the individual farmer is beginning to specialize in the apparatus which he employs on his farm. No small number of agricultural implements now used by the farmer have their functions so combined with those of other implements which have heretofore been of general application, as to supersede the latter, and, consequently, materially specialize the type of apparatus and vehicles which he uses for other purposes. The advent of the automobile, while not directly responsible for it, has tended to facilitate this process.

At one time there were a dozen uses for a certain kind of wagon which might be described to-day as an unspecialized type. To-day a number of agricultural implements accomplish in themselves a part of the services which were heretofore accomplished by such wagons; and, with one exception, the remainder of the services performed by that wagon is now found to be better performed by a more specialized type; that exception is the transportation of the farmer and his people from one point to another. The new specialized type is not convenient for this purpose, and the farmer resorts to the automobile. He goes to town every day perhaps, and spends very little time in doing so, instead of every week at the expense of an entire day and service of "a team."

The automobile makes the quarter-section farmers near neighbors and develops a sense of community in agricultural districts which was utterly impossible with the former methods of transportation. It makes the farmer's life and surroundings much more liberal, and, under many conditions, far more attractive even to the young people than the life of the city.

As an example of the part the automobile is playing, and can be made to play, in the affairs with which he is concerned, it may be interesting for Mr. Hill to know that at the time the Belgian steel operators were migrating to the Baltic provinces of Russia in great numbers, the resulting reduction in the population of some parts of Belgium was such that underwriters of certain extensions of the Belgian railways seriously considered availing themselves of the use of the automobile to protect themselves against what would have been a decidedly unprofitable execution of that part of their obligations which called for the extension of the railway in the partially deserted districts.

The broad principle underlying this is, of course, equally applicable to any sparsely populated territory, irrespective of the cause of that sparseness. We venture the opinion that if the dissection of the census of 1920 is such as to reveal it, it will be found that the migration during the preceding decade will have been from the city to the country, at least in a large part of the United States. We are not so sure that the census of 1910 might not already reveal a tendency of this kind, provided the concentration of immigration in cities does not entirely obscure the question.

Mr. Hill should recognize the automobile not as a disadvantage to the agriculturist, but as one of the most potent factors cooperating with his own splendid efforts and accomplishments toward agricultural development.

In spite of this somewhat minor criticism, we cannot but feel that it will be a good thing if Mr. Hill's address were published in pamphlet form as a text-book in the schools.

Iowa's Gumbo Was Found Deep and Sticky

Many Impromptu Receptions Held En Route

BAY STATERS IN A DOUBLE TRANSCONTINENTAL TOUR

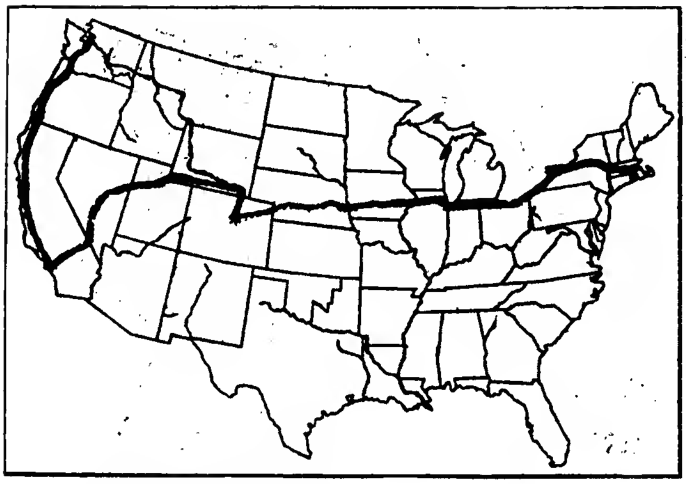
SEATTLE, WASH., Sept. 20—From Lowell, Massachusetts, to Seattle, Oregon, is a far cry by train, but it is still farther by automobile, and especially so if the route selected wanders over most of the boundless West before reaching its destination. It is not always the volition of the tourist which impels a roundabout course, but more often because of the absence of roads and of bridges, with a result that can be imagined only in part. Over 5,100 miles of all kinds of country can be traversed in journeying from the Bay State to the shores of Puget Sound when the itinerary includes a run of 3,700 across these wide United States, and another important item of 1,400 miles from Los Angeles to the North. This is the westbound outline of a transcontinental tour recently completed at this point by Ira H. Morse, Mrs. Morse, and a mechanic, Omer Deschenaux, all of Lowell, Mass., in a Pope-Hartford runabout, with full traveling equipment.

For two and a half months they and their car were constant companions in making this long run from ocean to ocean, and nearly all of that time was spent upon the roads, for the intention at the start was to make the trip for pleasure entirely, and not for a record. Since the eighteenth of May they have been experiencing every conceivable kind of roads, some of them not worthy of the name, interspersed now and then by some fine highway traveling. No one who has ever made a long tour can fail to appreciate the difficulties which they encountered, but those were all expected, and were far overbalanced by the pleasures, the interesting points seen, and the jolly good time "in communion with nature in her visible forms." For instance, can there be anything more pleasing to the average person than to camp out, with a good tent, a flowing stream from which fresh fish can easily be obtained, and perhaps not another person within a score of miles to break in upon the scene?

Early in the spring Mr. and Mrs. Morse decided that they would like to try desert driving and real mountain climbing in a tour to the Pacific Coast, and forthwith made their plans. Both had been over the ground in trains, and knew somewhat of the conditions which would confront them, and even went so far as to plan a return trip, thereby going better than the average transcontinentalists—those who ship their cars back home. The affair was purely a private venture, and not in the slightest manner connected with factory or agency. The car is a regular stock Model M runabout, with a four-cylinder motor of 35 horsepower. The rear was arranged to carry baggage. the tent, supplies of food and fuel, and so for the chauffeur a small seat was placed on the left running board—really the most comfortable place to ride on any car. A complete camping outfit was obtained, with blankets, cooking utensils, and boxed supplies; and for use, if needed, were added firearms, fishing tackle, block and tackle, heavy hickory sticks for prying, and a spade. The machine had previously been driven on long trips into the wildest portions of Maine and Canada, and in all had traveled over fully 18,000 miles of all kinds of roads. All the members of the trio are skilful drivers.

Bridge-Building on the Prairies of Colorado

Wyoming Roads Were Often Steep and Rough



Transcontinental Route of I. H. Morse and Party

Thus prepared for one of the longest continuous automobile trips ever made, the party left the City Hall garage, in Lowell. on the morning of May 18, and immediately headed west. The route chosen was the usual one, crossing to the valley of the Hudson, and passing through Albany, Syracuse, Buffalo, and Cleveland, reaching Chicago on May 27. In nine days the car covered 1105 miles, despite the fact that heavy downpours necessitated a longer stop than usual at Valparaiso, Ind. Three days later they were in Marshalltown, Ia., when Mr. Morse wrote in his log book, "Since Chicago the traveling has been very slow. The hard showers at night have made these black gumbo swamps, for which Iowa is notorious, hub deep, and the mud sticks to the car like glue, probably 200 pounds not being an exaggerated estimate of the amount collected. The car is acting to perfection, not a skip in the motor, and with power enough to plow through black mud for 100 miles yesterday. We were in some bad washouts, too, and in one case there was a long steep hill which had been washed for its entire length. The sand was about three feet deep, it seemed, and ours was the first vehicle of any kind to go over it since the rains." Iowa was crossed by June 2, for on that day Mr. Morse and his compaions reached Council Bluffs, and the uppermost thought in his mind is well shown by the following expression: "If one wants to find out what the car is made of, it is only necessary to come out here and buck these gumbo swamps when it is raining. Our car is a great one. People here say that we have 500 miles of fine roads to Denver, and we hope to make it in three days. We will try the route via Kearney."

Could Not Take Glidden Tour Route

This, however, proved to be by far too sanguine a view of what was in store for them, and the tale is impressively told by the following extract, dated Denver, June 14: "When I wrote last I thought that I had been running over some pretty hard roads, and with tough experiences, but they have been beaten since. For 70 miles the bridges have been washed away, and after trying the short southern route to Denver—the way the Glidden tour expects to come—we had to give it up, retracting part of our course to reach that of the longer northern trails. These led, via Cheyenne, 120 miles longer than we had counted upon. One day there were seven streams to ford where the bridges had been washed away. In two cases where the water was four feet deep, old floating bridge timbers were used to make a new bridge on which to cross."

From Denver it had been the plan to take a southerly course, through Colorado Springs, Pueblo, Trinidad and Raton, entering New Mexico, and visiting Las Vegas, Albuquerque, and thence turning westward through Arizona, touching at Canon Diablo, Flagstaff, Williams, and the Needles. The last named is just across the line in the Golden State. Then there would be the Great Desert confronting the tourists, and Mr. Morse was rather dubious about crossing it, but he hoped to get through and then to Daggett, San Bernardino, and Los Angeles. But planning on paper is far different from the realization of those on the road. South from Denver the route was well-nigh impassable on account of rains, and there was absolutely no use attempting the trip. It was necessary to return to the mile-high city, and then go north to Fort Collins, Col. The middle route over the mountains was taken through Laramie and Evanston, Mont., and through some wonderfully beautiful scenery. Salt Lake City, Utah, and the towns of Ely, Tonopah, Goldfield, and Bull Frog, in Nevada, were those on this route, but the difficulties in reaching them are little suggested by that simple line-up of peculiar nomenclature. Los Angeles was reached on July 1, and a delegation of the automobile club met the real tourists at the outskirts of the city. The newspapers were much interested in the party, both as they approached the city and on their arrival, so that quite a hearty reception was accorded them and their Pope-Hartford. The odometer then registered 3,700 miles, but the strenuous grind had had no evident effect upon the machine, and it was simply filled with gasoline and oil in preparation for the run up the coast.

Quicksand Will Readily Engulf an Auto

More quotations from Mr. Morse give descriptions of the run from Denver to the Pacific. He writes: "We have had experiences varying from an exciting brush with prairie wolves to digging the car out of quicksand. The lack of bridges is the serious drawback to the use of the auto in the West, for beyond Colorado there is no pretense of constructing them. It is a case of ford. If the car becomes enmired the walk for horses may be a good many miles. Once when we had pulled ourselves out of two streams within a ten-mile run, we were informed that there were a dozen more in the next 30, so it was impossible to make more than about 40 miles a day. Last night we were caught in the quicksands and the car went in up to the body. The more we tried to dig the deeper it sank, so I walked 17 miles to town, secured four mules and went back. The car was so deep that the mules could hardly get it loose, but by prying up a wheel we were able to get it started. We were rather surprised and very much gratified to find that, in spite of the great heat and extra amount of work, that our engine did not get hot, and only once did we add to the radiator supply from our tank during the day. In Nevada we saw many cars, and there was really a nest of Pope-Hartfords there, all doing good work. I never saw so many Pope cars among so few people as at Ely, Tonopah, and Goldfield."

Several days were spent in visiting around Los Angeles, and then began the ride to the North, along the coast, toward San Francisco and Seattle, a jaunt of 1400 miles. Frisco was reached on July 20, having found fair roads for 200 miles, and then excellent for 300, in the run from Los Angeles. Another start was made on July 23 toward Portland, Ore., over bad rocky roads, with some very steep ascents, but the car was equal to all requirements, and reached Portland on August 1. Seattle, the westward destination, was reached on August 4, with the party in the best of spirits and highly enthusiastic over the journey, declaring that those who ride in trains miss about 75 per cent. of the beauties of the land. In addition, the open-air living is bound to benefit everyone, especially when a good camping outfit is carried.

A short stay in this city was planned, in order to see the Alaska-Yukon-Pacific Exposition, and to take some side trips to points of general interest, and then the return journey to the Atlantic began. A different route as far as Cheyenne was considered for the return, going directly eastward instead of toward the south. Spokane, Wash., Livingston, Mont., and the northwestern part of Wyoming formed the important directions on the outline. Montpelier, Ida, Granger, Rock Springs, Rawlins, and Cheyenne were on the map in that direction, with a run down to Denver as another. From that city the same route used in coming out was considered best for the return.

Detachable Wire Wheels Must Prove Worth

By Rolland C. Laurie

Wire Wheels Proved Worth at the Mont Ventoux Climb

NOW that interest is being aroused in the detachable wire wheel following various excellent articles on the question, it perhaps would be of interest to learn how the general public regards the detachable wire wheel from a practical buying point of view. The writer is connected as sales manager with a company manufacturing light automobiles, embodying in its design a detachable wire wheel, giving an option on a detachable artillery wheel. This wheel is built upon somewhat similar lines to the Rudge-Whitworth, with the attaching, of course, free from anything complicated in design because of the low price of the car.

The company experimented extensively with this wire wheel, had no cause for complaint and no breakages to report, and it was adopted only after serious consideration of the merits of a wheel of this type.

Now we come to the particular point: the placing of this before the public; and it is interesting to hear the various opinions of private purchasers and agents. The public generally seems to regard the wire wheel with distrust. First, a great many jump at the conclusion that the wire wheel lacks lateral strength, as Mr. Mackle pointed out in his article. This point has been disproved time after time in actual practice, and we can believe that a conservative nation like the British do not take up a design such as this unless really tangible advantages are clearly shown.

In a personal letter to the writer from S. F. Edge, the well-known British motorist, Mr. Edge says: "I have been using these wire wheels for over five years and nothing would induce me to return to the old artillery pattern." Such testimony coming from an authority is invaluable, but the extraordinary point is, taking the general public and averaging the majority of opinions, after they have been persuaded into thoroughly believing the truth of the superiority of the wire wheel, they come back to the appearance question and say that they do not like the looks of it. This is a point which I should like to emphasize. Throughout this year a great many callers have expressed the same opinion, and yet, when on a visit to England, I noticed that the wire wheel hardly struck one as being anything out of the common in design, so prevalent was the usage of it. Indeed, for appearance, taking the same car first with artillery and then with wire wheels, there is not the slightest doubt that once the eye has become accustomed to the appearance, the general aspect of the wire wheel is far more pleasing.

Daily, agents call upon the writer and say that they have full belief in the advantages which are claimed for the wire wheel, but that they fear to exploit a machine so fitted before the public because of the heavy "missionary work" involved. The public is slow, as a general rule, to grasp the significance of any step in the right direction in design, even if it does not bear upon the mere question of appearance. It took years for the magneto to be recognized as an improvement, but, in the end, the magneto won out, and is now universal.

When we have a great many leading foreign cars fitted with wire wheels, and proving the advantages thereof, there is no reason why wire wheels should be looked upon with suspicion. As for a detachable wheel, the advantages speak for themselves. The only criticism is, that instead of the usual British practice of carrying the same in a slot in the running board quite exposed to public view, it would be preferable to have some kind of a case designed to contain the whole wheel, as this would look somewhat neater. Obviously some kind of a looking pawl, such as a Rudge-Whitworth, is the best form of attachment for such a wheel, but this is somewhat costly to manufacture, and can only be included in the higher priced car. The attachment for the detachable wire wheel which has been on the market for nearly a year, and to which I indirectly refer from a practical standpoint, is merely effected by a central pinned bolt which passes through a drilled hole in the hub shell.

From a selling standpoint, until the public become educated to the wire wheel through the medium of advertisement, the road for the pioneer in this respect will be a stony one. Having had experience in the matter, I can speak from a practical standpoint. It is extraordinary to note the attitude of a buyer when he views this wheel. I have had the wire wheel termed a "bicycle wheel" by a would-be buyer, and the only recourse of my company was to place on the road demonstrating cars fitted with the alternative, artillery wheels; and, generally speaking, the public vote for this wheel every time, in spite of the fact that even *they* are willing to admit the superiority of the wire wheel from a point of view of correct design.

Generally a private buyer fears to be driving a car fitted with anything out of the ordinary in design which may stamp it as "cheap," and this can be easily accounted for from the fact that some of the earlier forms of light automobiles were fitted with inefficient and badly designed wire wheels which gave trouble and earned a bad reputation. Of course, I am only speaking from an experience of this wheel in conjunction with a light runabout. It is yet to be experimented with by any well-known manufacturer, as this might make some difference if applied to heavy touring cars, for here one reaches a different class of buyers, the greater number of whom have probably seen this wheel abroad and therefore already know its merits.

But for the manufacturer of light automobiles of the runabout type I may say from experience that the work of introducing such an improvement is uphill in the extreme, because of the lack of cosmopolitan element among purchasers of this type of car. The majority with whom I have come in contact have never even heard of the success of the wire wheel in England. All they have to judge from are the examples of the old type of wire wheel, which undoubtedly was imperfect in design and again was not the detachable variety. Certainly the public appreciate quick detachable wheels, and the advantages thereof; that I have found from experience; but until this matter has been experimented with by a manufacturer of touring cars, the maker of runabouts has no chance, because of public prejudice.

Cannot Pawn Automobiles—The French Government pawnshops have declined to make any further advances on automobiles, for it has discovered a peculiar action of certain owners. Parisians who pass two or three months of the year at places where automobiles have little use have found that to pawn them is a cheap way of having them well cared for during the summer.

STANDARDIZATION GATHERS FORCE IN BODY WORK

ADVANTAGE is realized at no inconvenience when account is taken of general practice in body work as well as in mechanical designing. There may be no apparent direct gain in following in the path blazoned by a previous worker in the same vineyard, but experience is always a cashable asset, and things done are natural models to go by.

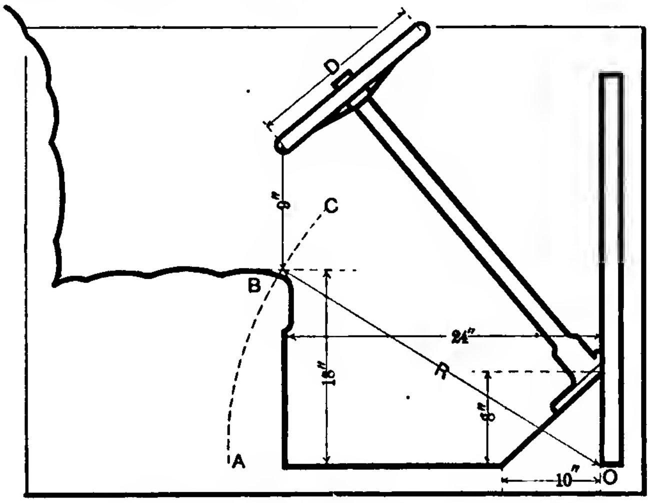


Fig. 1—Diagram showing seat and steering post dimensions

Take the driver's seat, for illustration. Why should a motorist have to get used to a different set of dimensions when he climbs out of one car into another? Referring to Fig. 1, it will be observed that the distance from the back of the "dash" to the front of the seat is 24 inches; this dimension obtains to a great extent in various cars, and if it is a sufficient distance, why should not motorists have the benefit of this measurement in all makes of cars? If it is not enough, why should body makers use this dimension? In the same figure the slant of the foot-board is that due to an elevation of eight inches, and ten inches back. If this is a convenient slant, why not standardize it? If it is not a good slant, why use it?

If the seat is 18 inches from the deck, when the distance back from the dash is 24 inches, is it not self-evident that the seat should be moved back to the radius R, on the arc A C, cutting the point B when the seat is less than 18 inches up from the deck? If the distance from the rim of the steering wheel at its low point is nine inches as a rule, would there be any objection to having this dimension fixed, so that autoists would become accustomed to the position and feel "at home" in every car at a moment's notice?

Granting that there are good reasons why all cars should not have the same length of wheelbase, even so, this does not make it necessary to employ hybrid lengths of bodies; surely a body can be some one of a regular set of lengths. Fig 2 shows the prevailing lengths expressed in metric measurements for even values, with English equivalents. The differences are represented by about five-inch increments and it would be a positive advantage to a buyer of a car were he in a position to purchase a new body in a year or so, when the style changes, as it frequently does, thus bringing his old car up to date in point of appearance at any rate, and with standard dimensions it would be possible to explore the open market, procuring a body from stock, quickly, and at a reasonably low figure.

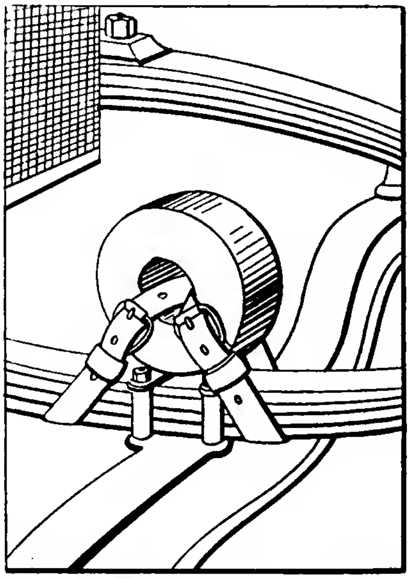

Fig. 3—Suggested standardization of clearance for frames

That the clearance should be minimized is one of the fixed principles of designing on the count that the lower the center of gravity the better will be the behavior of the car. Certainly the center of gravity will not be lowered by perching the body high in the air; the distance C, then, remains to be fixed on a basis such as will afford an adequate clearance, and no more. Under the circumstances it would appear to be the height of good sense to standardize the clearance, taking into account a reasonable vertical bounce of the body, when, if the springs are not up to a suitable standard, the idea depicted in Fig. 3 represents the cure.

SOME OBSERVATIONS ON THE STEERING GEAR

By THOS. J. FAY.

OWNERS of cars naturally consider that the steering gear is of even greater importance than the motor, for if the motor fails to work, it will have to be fixed before the car will be capable of rendering service, but if the steering gear fails while the car is in motion, the speed may be high enough to engender serious consequence.

It is not necessarily true that there are more accidents, due to defective steering gear, than was formerly the case, although there are more inexperienced autoists simply because there are more cars in use. Defects in steering equipment, from original causes, are probably on the decline, so much so, in fact, that the large increase in the number of cars in use has not led to a vast number of accidents directly traceable to defective gear. Still, the problem is a serious one, and the remedy lies in the use of well-made linkages. levers, and a steering wheel of undoubted competence.

Even if the equipment is of the very best possible to devise, it is likely to go awry in the hands of a man who fails to appreciate the enormity of the task involved in holding a car to the straight and narrow path, when the path is rough, and the speed of the car is high, with many turns around which the car is allowed to spin. If autoists will attend to the main question, which is a matter of keeping steering gear in good working order, and drive with prudence, especially when the road is rough and the turns are many, the number of accidents due to defective steering gear will sink so low that the "news value" of the automobile will fall below a noticeable standard. In the meantime, the preference, when cars are being purchased, will go to the class in which steering gear is given a fair measure of designing attention.

Certain Points of Design Uppermost—Of the points which should command the attention of users of cars, lost motion in the steering gear is of the first importance. It may be due to a bolt, or a nut, adrift, which will cause trouble of a serious nature. If there is more lost motion than would seem to be desirable, it may be that the worm and sector, if the gear is of that type, is not held in the proper relation. Fig. 1 depicts a

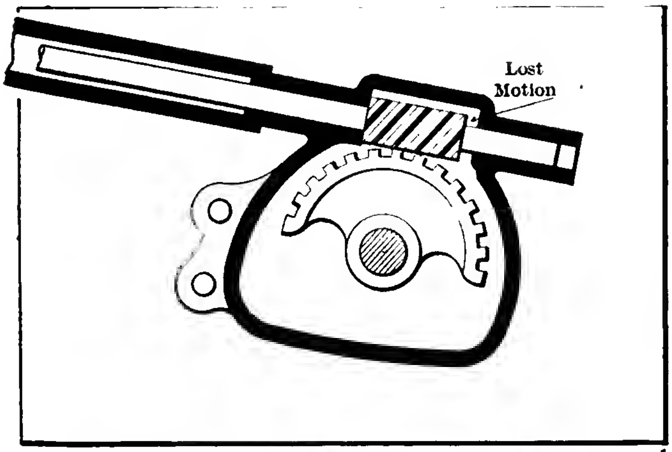

Fig. 1—Possibility of lost motion should be avoided

worm and sector type of steering gear, in a diagrammatic way, intended to show just where the lost motion, if such there is, will be of the greatest detriment. When the wheel is turned, if there is a little end play (far less than the figure indicates), the wheel-shaft will respond, but the sector will fail to do so. Until all the end-play is taken up, the sector will fail to rotate. and as strains come on, from the road wheel, the sector will then rotate, causing the shaft of the steering wheel to reciprocate, and the road wheels to wobble from side to side, in an alarming manner. To overcome this trouble, it is necessary to replace the thrust washer, if one there may be, and if necessary, introduce a washer, made of phosphor bronze, of suitable thickness to take up all the end shake of the steering wheel shaft.

Some lost motion will follow if the worm is not set on the pitch line, in its proper relation to the sector; this will be true if the bushings are worn, and when a new thrust washer is made and fitted into place, if the lost motion is still in greater presence than is desired, the only thing remaining is to replace the bearing brasses. When the gear is dissembled, it will be possible to dimension the same and determine by measurement if there is any great amount of journal wear, thus rendering the task less troublesome, since the brasses may be replaced without waiting to determine the remaining lost motion through actual trial.

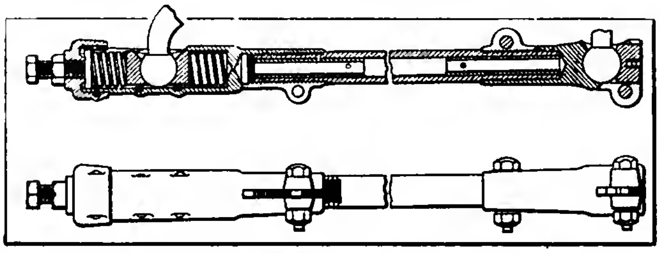

Fig. 2—Drag rod construction which shows merit

As a rule, it will be found that the lost motion is due to end shake, just as the illustration shows, and not to worn-out journal brasses on which the wear is far less than it is in thrust. If the gear is irreversible, or nearly so, as it is in many automobiles, a little lost motion is to be expected owing to the smallness of the angle of the worm, which can only be irreversible if the angle is such that a little lost motion will be present and unavoidable.

Drag and Cross-Rod Should Be Well Designed—Fig. 2 illustrates a type of drag-rod, which is of the greatest value in actual service, due, in a measure, to the use of a buffer spring. so placed that shock cannot be imparted to the materials of which the parts are made, not only in the rod, but in the rest of the steering equipment as well. Besides aborting shock, the design is such that great reliance may be placed on the parts, due to the use of good material, and the methods of design which assure permanence. The socket forgings are of a fine grade of steel, drop-forged and heat treated to render them hard over the bearing surfaces, and dynamic, which is the property that assures long life under conditions of shock loading.

The socket forgings are accurately machined, threaded to match threads cut on the tubing, and when they are screwed on, proper means are provided to lock the forgings, so that to screw them off, it is necessary to unlock them; under these conditions, for the parts to come off while the car is in motion, is quite out of the question.

Brazing Works When It Is Well Done—Many workmen labor under the impression that a brazing job cannot be done unless the parts are a loose fit, in order, as they say, to allow the brazing material to enter and form a bond. The result is. when they do the work, the parts are a very loose fit, with accentuated shearing tendencies in the section of the brazing material, and if the brazing happens to be poorly done, the result is anything but good, since, in the absence of brazing, there is not even a good mechanical bond.

A good mechanical bond is possible to procure without, in any way, interfering with the brazing process, since the parts. if they are well fluxed, will take a coat of brazing material, even when the recess is but a thousandth or two. In brazing, if the work is to be up to a sufficient standard to use in steering gear. it is necessary to clean and brighten the surfaces in a most thorough manner. This will best follow by mechanical scraping

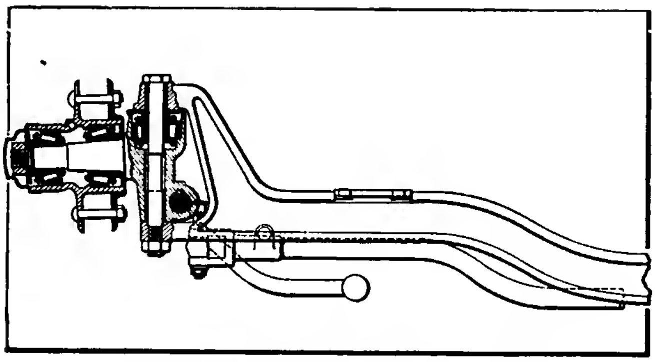

Fig. 3—Large pivot bolts make for long life

rather than by dipping in some corroding material. Dipping may be of value as a preliminary, but a file, and scraper, in the hands of a man of competence, will go a long ways toward success.

When the parts are well brightened and the grease is thoroughly removed, by the use of soda water, benzine, or equally good solvents, it remains to flux the parts with borax, and then apply the heat, either by a forge or from a Bunsen burner; if fire brick, or clay, is used to build up around the parts, the heating process will be attended with less difficulty, and the work will be in better fettle at the finish. A rather hard brazing material may be used; this may be purchased ready for use, and there is no reason at all why a motorist of but slight skill can not make a good job of brazing.

Steering Knuckles Should Be Carefully Examined—Even if the class of work found in a car, when it is purchased, is up to the very highest standard, it is the height of good judgment, on the part of every motorist, to examine the gear and the knuckle details, at regular intervals. Fig. 3 depicts a regular make of steering knuckle, in which the design features are up to a fitting standard, and all that the user can be expected to do is to keep the parts free from dirt, lubricate with regularity, and on occasions, ascertain if lost motion is creeping in. As will be observed, a pivot bolt, of excellent proportions, passes through the forging; is provided with a head to prevent it from dropping down, and a castellated nut, on the under side, holds the pin.

This knuckle pivot bolt, while it serves to center the Timken roller bearing, as shown in Fig. 3, also serves to hold the plain bearing, at the bottom, and being of a fine grade of steel, it is of the greatest advantage from the point of view of strength and safety in service. Looking at Fig. 4, it is to note a knuckle, made of steel casting, in which a knuckle bolt is not used, and if the knuckle fractures, as it may in service, the absence of a through bolt is attended by dire results. Of course, there is a great difference between the use of die-forged knuckles, of selected grades of steel, which marks the construction of the steering knuckle as depicted in Fig. 3, in contrast with the steel casting product as shown in Fig. 4. Absolute safety would dictate the use of the finer material, which is no license to do without a knuckle pivot bolt of competence and bearings such as will take thrust in addition to radial pressure.

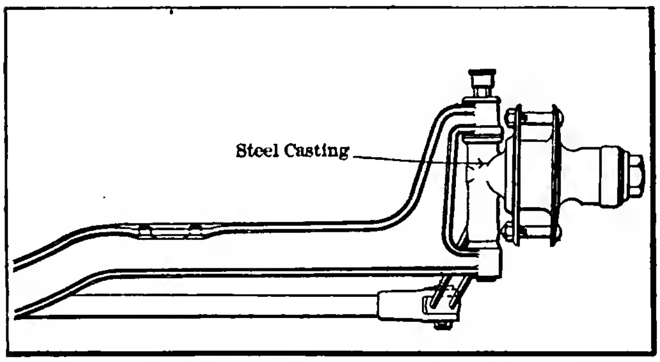

Fig. 4—Absence of a through bolt is dangerous

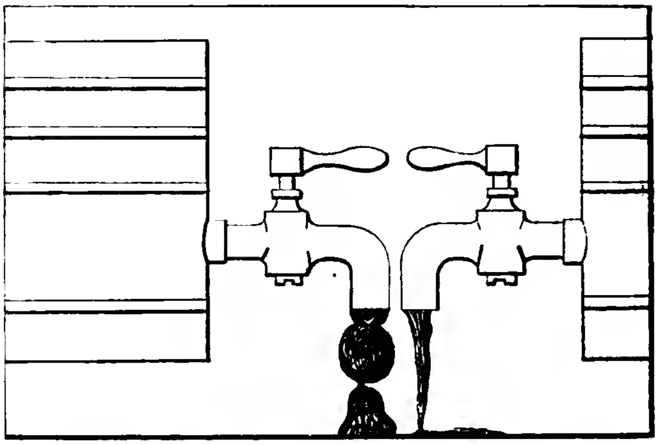
Arrangement and number of the bearings as well as the type of bearing used have much to do with the success or failure of any form of front axle, with which failure the best of steering gears is worthless. This is a matter that should be looked into, not superficially, but with care and great thoroughness, for not only is it a matter of moment, but a source of great danger as well. The same thing applies, although with lessened force, to the steering gear bearings. With the worm or similar type, there is a very heavy thrust load, which must be taken care of by means of a thrust bearing, since an ordinary radial-load bearing will not suffice. As improper mounting of this may cause it to seize, the whole design should be critically examined.

Materials also should receive the attention of the careful man who is buying his first car, particularly if he cannot afford to pay out a lot of money for repairs. Thus, it might be said in a general way, that other things being equal, a piece made of a forging is superior in strength to a piece which has been cast. Any metal which has been worked under the hammer, either hand or power, has been improved in quality of grain and strength, as well as reliability, if the metal has not been burned in the various heating processes.

VISCOSITY OF GASOLINE INTERFERES

Viscosity, which is a well recognized property in connection with "molasses in January," also impedes the flow of gasoline, in extent, depending upon temperature. The illustration, as here afforded, is a little far-fetched, yet even so,



Effect of Temperature on Liquids, as Molasses and Gasoline

it may be of more than ordinary value, particularly if it will accentuate the point to be made.

It is a mistake to assume that, because gasoline does not noticeably thicken up, it is not interfered with in its flow through the nozzle of the carbureter. Taking gasoline of a specific gravity of 0.71, it has been shown that the amount which will pass through a nozzle of a carbureter under a given pressure will increase as the temperature is increased in the manner as follows:

Temperature in ° F.	50	59	68	77	86	95
Relative flow	1	1.073	1.145	1.212	1.27	1.335

Since nozzles in carbureters are not adjustable readily, and with any degree of certainty, it follows that such a great difference in the weight of fuel ejected, considering the differences in temperature named, is bound to lead to a certain amount of carbureter inefficiency of the kind which does not readily bow to treatment. This source of trouble goes to indicate that some means of maintaining a constant temperature is of the greatest advantage, and in a measure it argues for the adaptation of water (hot) jacketing, not around the depression chamber, as is usually the practice, but around the gasoline (float) bowl, in order to maintain a constant temperature of the liquid gasoline as it flows through the nozzle.

HOW ONE AUTOMOBILE WAS BUILT

As striking proof that the family constructive ability is not confined to the older heads of the family, nor to the ability to make a good piano, an automobile recently constructed by two of the younger members of the Steinway family in New York City is a worthy example. This as presented on this page by a series of photographs of the finished car, was what is called an assembled product, in that the large units were purchased and assembled at the Steinway factory, Fifty-third street and Park avenue. The two young men responsible for the car, as shown alongside of it in the first picture are William R. and Theodore Steinway, who are grandsons of the founder of the piano business, and have served a four-year apprenticeship in the factory.

For the power plant, a Brownell was selected, this consisting of an engine, clutch, and transmission unit, the lower part of the cases being one piece. The engine is of four cylinders, 3½ bore by 4-inch stroke, rated conservatively at 17 horsepower, and is hung from three points, two forward arms and a rear pivotal point. The transmission is of the selective type affording three speeds forward and a reverse.

In selecting the running gear and frame, the pleasing lines of the B. L. M. type of frame, as made by the Merchant & Evans Company proved most attractive, while the rest of the running gear, as well as the steering gear, was obtained from the Stoddard-Dayton people. In placing the latter in the frame it was given considerable rake, while the large steering wheel lends the whole rather a racy appearance.

Ignition is of the double type, Bosch magneto furnishing the current in one case. A single set of plugs is used and they are placed in the side of the cylinder casting, thence projecting into the combustion chamber. The square-tube honeycomb radiator, their own design, was built by the A-Z Company, New York City.

The elimination of the usual rear seat or rumble allowed of making the frame very short, the 92-inch wheelbase, in combination with the narrow, 50-inch tread, making it possible to turn around in the narrow city streects. Back of the seats is carried the seamless steel gasoline tank, which holds 10 gallons, this being sufficient fuel to travel more than 150 miles.

Wheels are of the wood artillery type, 30 by 3½-inch, fitted with Goodrich quick detachable rims and Republic Staggard tread tires. The ratio of the gearing of the live axle is such that a speed of 35 to 40 miles per hour may be attained.

Other small and special parts, necessary to fit the various units together into a symmetrical whole, were designed by the constructors, and either forged or cast right in the factory. Aside from the help afforded by the machinist, all of the work was done by the two Steinways, so that the car as finished is actually "home-made."

AEROPLANE STABILITY

Editor THE AUTOMOBILE:

[2,027]—In an article which appeared in "The Automobile" of September 2 there was a statement to the effect that as yet there had been no device of any kind incorporated into an aeroplane which would automatically balance it, when in flight.

In your estimation what would be the prospect for an appliance which would positively and automatically balance an aeroplane?

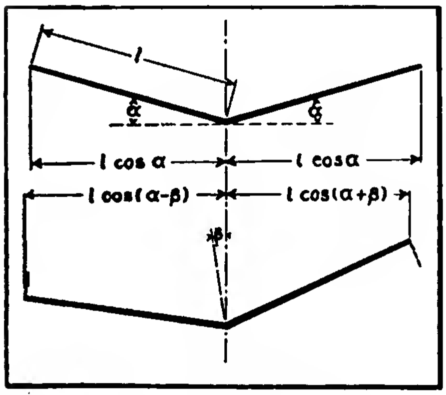
What is the pressure required, approximately, to warp the planes of a Wright aeroplane to their fullest extent when the machine is flying at its greatest speed?

Ottawa, O. L. R. B.

The statement that no device had yet been incorporated in an aeroplane to maintain its stability automatically should have been made with a reservation. The construction of practically all aeroplanes is such as to materially aid in maintaining stability. When the center of gravity of the machine is below the center of support, it has a natural tendency to remain upright. If the weight is hung too low, however, it has a tendency to act as a pendulum and rock the machine. Another idea, best exemplified in the Antoinette monoplane of Latham, is to set the wings at an angle with each other. If the machine tips to one side, the surface on that side increases and on the other decreases. This will be made plain by the diagram.

Either or both of these plans, however, appear to be insufficient to resist a sudden and violent disturbance of the air currents. Thus even the Antoinette has, in addition to its slanted planes, a system of auxiliary wings like those used by Curtiss; and the Bleriot monoplane No. 22, in which the low center of gravity is particularly prominent, uses the wing-warping system of the Wright Brothers. The statement of the previous article, therefore, is correct if understood to refer only to the control of the auxiliary wings or of the warping, which resists disturbances otherwise likely to overcome the machine's natural stability.

There is undoubtedly a great field for an appliance which will positively and automatically balance an aeroplane; obviously aeroplanes cannot be a safe and dependable means of transportation as long as they depend for their stability on the strength and skill of a single man. But the problem of inventing such an appliance is by no means as simple as it might appear. The inventor's first thought is to use some application of inertia, either the pendulum or the gyroscope. The pendulum, however, has proved too sensitive to the acceleration of the machine, which has the same effect on the hanging weight as an inclination. The gyroscope seems more promising, and it is likely that some form of it will ultimately be used.



Explaining Aeroplane Stability

If absolute stability can be secured by the construction of the machine, without the use of special contrivances, so much the better. It would naturally occur to one to try a combination of slanted planes and low center of gravity; and this line was followed by M. Santos-Dumont last winter. He was then working on the forerunner of the machine with which he recently flew five miles at the rate of 56 miles an hour. This experimental machine carried both the engine and the operator on an underslung frame; that is, at least two-thirds of the total weight at a distance of some three feet below the center of support. At the same time the planes were sharply inclined, at an angle of about 10 degrees. Now, in the machine which was the result of experiments with this trial model, both these principles were abandoned; the motor was placed on top of the planes, nearly as far above the center of support as the aviator is below, and the planes were set flat. Although we have no knowledge of M. Santos-Dumont's reasons for the change, the inference is that the original construction was found unsatisfactory. This apparently leaves a clear field for the man who will invent an automatic control for the auxiliary planes or warping.

In answer to your final question, we have no exact means of determining the pressure necessary to warp the planes of a Wright aeroplane. The only way to find out would be to apply a spring balance to the operating lever while the machine is in flight, and we doubt if Mr. Wright could be persuaded to try the experiment. However, it is quite simple to find an approximation which the necessary pressure at least could not exceed. The maximum force which a man can exert horizontally on a lever is about 25 pounds, and as the leverage between the controlling handle and the planes appears to be in the ratio of about three to one, this would give 75 pounds, directly applied, as the maximum possible force. The true figure is probably considerably smaller.

Mr. Curtiss has worked out an ingenious method of operating the lateral control, by a harness around the aviator's shoulders. The instinctive swaying of the body thus moves the auxiliary planes.

THE VACUUM AIRSHIP

Editor THE AUTOMOBILE:

[2,028]—In the August issue of "Machinery" I noticed an article recommending the development of the vacuum airship. The author has apparently made careful calculations for a ship 750 feet long and 150 feet in diameter; I checked over the figures and found them correct. He states that the envelope would contain 420 tons of air, which would be exhausted sufficiently to obtain a lifting effort of 370 tons. The airship itself would weigh 270 tons, leaving 100 tons for passengers and freight. The project seems very plausible, and I, for one, cannot see anything wrong with it. Perhaps the readers of "Letters Interesting and Instructive" would be interested in a discussion of this project. I notice that your magazine has always given much more attention to aeroplanes than to airships. J. B. WINTHROP.

Brooklyn, N. Y.

We read the article to which you refer with considerable interest, and, like you, checked over the author's calculations without finding any flaw. There are two very important objections we wish to raise, however. The first relates to the practicability of building the ship as light as 270 tons. This objection is passed over in the article with the comment that "the entire system has been worked out to the final detail, and has been attested by engineers of national reputation." We are hardly convinced by this statement. This point is crucial in the argument; the question of weight has been raised against the vacuum airship each time it has been proposed before, and has never been successfully answered. Yet the author casually says that he has solved this difficulty, and does not even give the names of the engineers who have supported him. A few calculations would have been better.

Moreover, it is not alone sufficient to provide that the framework shall resist the normal pressure of the air; it must also be calculated to resist very considerable bending moments and buckling stresses, due to being forced through the air by its engines.

Our second main objection rests on the possibility of obtaining as high a vacuum as is counted on. Exhausting 370 out of 420 tons of air corresponds to a vacuum of 30 inches, which is the highest that has ever been attained in steam turbine practice. Anyone who has ever observed the infinite precautions necessary to obtain and maintain this degree of vacuum in a turbine plant will be skeptical of obtaining the same in an airship, where both weight and space must be economized. In our opinion it will be absolutely impossible to make the numerous joints in the 0.018-inch steel sheets (the size specified in the article in question) sufficiently tight to hold this vacuum.

However, the article is completely discredited by the statement that the airship is designed for a *minimum* speed of 100 miles an hour, a ridiculous claim.

MORE OIL COOLING

Editor THE AUTOMOBILE:

[2,029]—I would like to learn through your department of "Letters Interesting, Answered and Discussed," if a light oil, such as Havoline, would be safe to use instead of water in the radiator of a car with a four-cylinder vertical engine, of the thermo-syphon system of cooling? Last winter I used a mixture of one-third alcohol, glycerine and water, but found it troublesome, owing to the evaporation of the alcohol. I am inclined to try oil this winter, and want to know what you think of it. J. A. RENÉ.
Superior, Wis.

This is a point that was covered in the letter (2019) of E. W. J., which was published in our Sept. 16 issue, except for the thermo-syphon point. This latter will be sufficient to bar the use of oil, as the latter is so heavy that it will not circulate except through the energetic action of a good pump. If you are in a position to add a pump to your circulating system, oil will do very nicely, as brought out in the letter referred to. We cannot give you a table of the properties of oil at low temperatures because no such table is available.

In case you did not like the mixture used last winter, why do you not try a calcium chloride solution, with which any desired temperature within reason may be obtained, and which is free from the objectionable evaporation you mention? That is, when using this, only the water evaporates, and this may be replaced by simply adding more water. Then, about once a month, the specific gravity of the mixture should be checked up. The only reason for this lies in the fact that if allowed to get too strong, the calcium chloride will precipitate out and this precipitate, in the form of a white powder or crystals, will clog up the system and prevent the remaining liquid from circulating. As the accompanying diagram of the freezing points of various strengths of calcium chloride solutions will show, the temperature desired may be attained by varying the amount of calcium.

The best way to make the solution is to first make a saturate solution of the chloride, and then use this, by adding water to it until the desired mixture is reached. This is done by taking half a gallon of water to 8 pounds of chloride for each gallon of saturate solution desired. It is a good idea to make a gallon or so extra to have on hand. You can tell if this makes a saturate solution by the fact that some of the crystals must remain in the bottom undissolved. If this is not the case, add more crystals until some of them will not dissolve. This solution is made applicable to the cooling system by adding to it more water, and finally when the right proportion is obtained, a handful of lime to render it slightly alkaline. The latter is done as this solution is said to have an acidic action on the metals of the whole cooling system. As the latter has never been proven, the simple precaution of the lime will counterbalance it. The diagram shows plainly what temperatures may be obtained by this solution.

SAVANNAH WINNER'S SPEED

Editor THE AUTOMOBILE:

[2,080]—Will you kindly publish in the next issue of your valuable paper, "The Automobile," the average speed of the winner of the heavy car race at Savannah Thanksgiving Day, 1908? JOHN A. HAMILTON.
Columbia, S. C.

At Savannah, the heavy car race was won by Wagner driving a Fiat. He covered the 16 laps of 25.13 miles each, a total of 402.08 miles, in 6 hours 10 minutes and 31 seconds, which is an average of 65.08 miles per hour. It might be interesting to you to know some of the details of the car. It was a four-cylinder motor of 155 mm bore by 160 mm stroke, practically 6.1 by 6.3, and was rated at 120 horsepower. The car had 50-inch tread, 107-inch wheelbase, and weighed 2,750 pounds. The tire and wheel equipment was 105 by 870 fronts and 120 by 880 demountable rear tires, all being Michelins. These sizes converted into inches and fractions are: 4 1-8 by 34 1-4 fronts and 4 3-4 by 34 11-16 rears. The car has double chain drive and Bosch magneto.

USE OF UNIVERSAL RIMS

Editor THE AUTOMOBILE:

[2,031]—Will you please inform me on the following matters? I have regular clincher rims on my car. If I have universal rims put on can I use my same old casings with safety, there, of course, being no lugs on the universal rims? W. SEVERANCE.
Stanford, Ky.

Yes, when universal rims are fitted to wheels for the express purpose of using old clincher tires on those rims, special flanges are supplied which hold the clincher tire safely on the rim. Then when the old clincher type of tire is worn out, and new ones are purchased, it is possible to obtain another set of different flanges which will hold the regular style of tire intended to be used with those rims. That is, with the exception of the flanges, which represent a very small expense, the universal rims are just what the name implies, universal, any kind of tire may be used with them, and, of course, used with safety, which is implied

WANTS LARGER TIRES

Editor THE AUTOMOBILE:

[2,032]—I have a car which is several years old and equipped consequently with very small tires. I have added a number of things to the extra equipment, as well as changing several parts of the mechanism. All of these changes have added to the weight of the car, so that now I feel that the weight per tire is too large for the tires now on the wheels. This contention is carried out in driving by the very low mileage which I obtain from the various tires. Now, I need another set of new tires and instead of getting the same old too-small size, I want to get the new larger sizes. To do this without buying new wheels, which I do not care to do now, I must use odd sizes. Can you give me a list of the odd sizes now obtainable, as well as a list of makers who make them, and local dealers who handle them? G. J. O'HARA.
New York City.

Your decision to use larger tires is a very wise one, and is to be commended. The so-called "odd sizes" have not been made very long, and even now are not

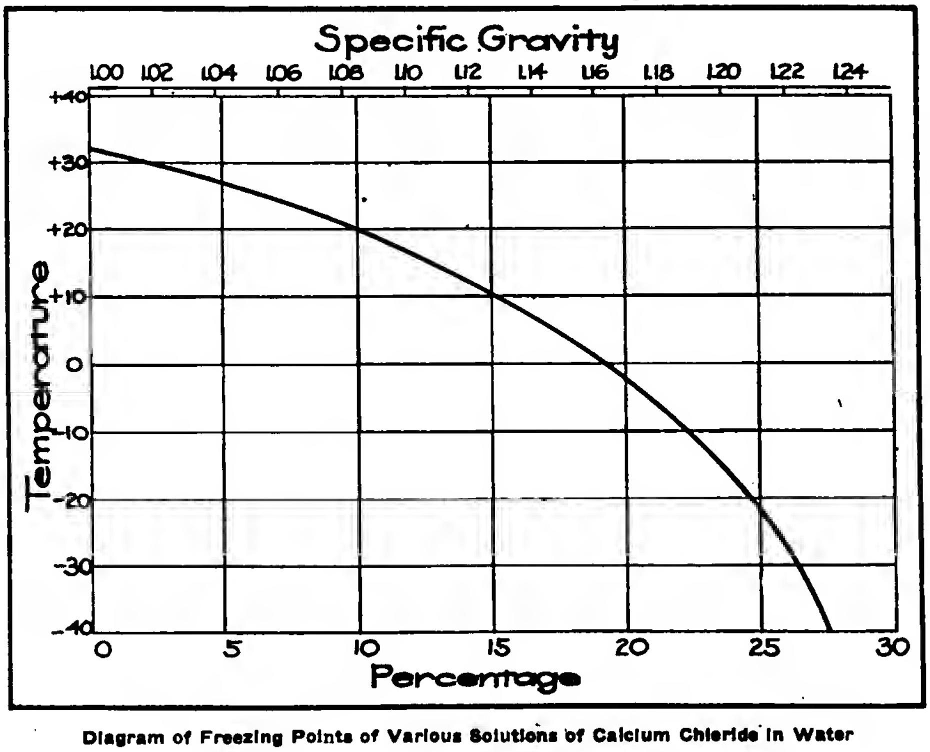


Diagram of Freezing Points of Various Solutions of Calcium Chloride in Water made by all makers. In fact, we would not care to give you a list of either makers or dealers who make or handle them, for we are not at all sure how many manufacturers have taken to them. On the other hand, we can help you to the extent of giving you a list of such sizes as have been made, and probably are made now. These are:

New Sizs	Old Rim Which it Will Fit
28 x 3 1-4	28 x 3
31 x 3 1-2	30 x 3
31 x 4	30 x 3 1-2
33 x 4	32 x 3 1-2
35 x 4	34 x 3 1-2
35 x 4 1-2	34 x 4
35 x 5	34 x 4 1-2
36 x 5 1-2	34 x 4 1-2
37 x 4	36 x 3 1-2
37 x 5	36 x 4 1-2
38 x 5 1-2	36 x 4 1-2
39 x 5	38 x 4 1-2
41 x 5	40 x 4 1-2

In making the change, it will be advisable to go to the largest size you can get for your rims as the table above shows.

VALVES MAY CAUSE IT

Editor THE AUTOMOBILE:

[2,033.]—I desire to express my appreciation for your answer and opinions to my letter No. 1,990, published in "The Automobile" of August 26. Have followed out your suggestions, but have been unable to detect any thing at fault with the water-circulating system. I feel quite positive that the source of trouble does not lie there.

Could not the trouble described, however, be caused by defective valve action? The valves sticking in their guides, due to a too close fit, or lack of lubrication here, or because the valve stems have become encrusted with carbon or gummy oil. Would not a heavy oil be apt to help in causing this trouble?

These questions show the line on which I have been working. I am not sure that I am correct in my deductions yet after the valves had been cleaned and ground, no trouble arose in taking the hill that I mentioned in the former letter. The unfortunate part of it all is, however, that after the car was driven about 600 miles I again attempted to take this hill and had a recurrence of the old trouble. Anything that you have to comment on this subject will be most thankfully received. SUBSCRIBER.

New York City.

Any one of the troubles mentioned might cause heating, that is, if the valve action is incomplete or sluggish, for any reason the engine is liable to overheat. For this reason manufacturers generally advise against the lubrication of valve stems. The argument in favor of this is that the necessary clearance is provided in the machining of the parts, and checked up or proven in the assembling of the engine. If oil is used after this it may be too thick and gum up the stem so that the valve does not function properly. If you grind in the valves to a good seat, and at the same time clean the stems and guides very thoroughly with kerosene, you may be sure that further immediate trouble of the same kind is due to some other and different cause, which will require a different treatment. On the other hand, if this stops the trouble you will know where to look for it next time.

The reason why the sticky valve stem causes heating is this: Gummy or sticky oil holds the valve against the action of the cam which tends to open it. Now, if this action is very strong it may even prevent the valve from opening at the time it was designed to and similarly cause it to be held open too long. The former in the case of the inlet would not furnish the engine sufficient fuel. Opening the throttle wider would furnish a richer mixture but the valves would not allow any more of it to enter. The two in combination would cause heating, as would also either one of them alone. Then, holding the exhaust valve closed after it was supposed to be open, would retain the heated gases in the cylinder and cause it to heat. This is a prolific cause of heating and one that marks the difference between the old and the up-to-date engine.

Formerly designers laid out the cams and valve motions so as to open the exhaust at the lower dead center. Later on experience taught that an earlier opening gave much better results. This latter might be paraphrased thus, if you are going to throw away the gases with their attendant heat, why not do it in a hurry?

As time passed and this method was proven right, the angle of advance or lead given to the exhaust opening increased until to-day it is possible to find very high speed motors in France having an opening as early as 62 degrees before the lower dead center. Angles as high as 45 and 50 are quite common, although no one angle could ever be said to be universal, designers differing very widely on this point.

HOT WALLS EXPLAINED

Editor THE AUTOMOBILE:

[2,034]—Your comments in a recent issue on the subject of hot cylinder walls indicate that you fail to grasp the full value of hot walls. I have had many people tell me that they knew a cool engine would pull better than a hot one because their engine lost power when it got hot. This is undoubtedly true. I have seen lots of men who could not fly, but the fact that one or more men have successfully flown demonstrates that flying can be done. So a single proof that a hot engine will develop more power than a cold one is sufficient. If one can do this, others can. Heat is the working medium in an engine. Take the heat away from the gases as fast as it is formed by the combustion and no increase of pressure results. Take away half of the heat and half the available power is lost. This can not be denied. It should need no argument to prove further that loss of heat through the walls is loss of power.

But if further evidence is required, attach an engine to a known load, a prony brake, or a fan, and work it at full power. If properly designed and lubricated, it will continue for hours. But turn cold water into its jacket and you at once cut down its power. This is due to cooling the walls and not only taking away heat, but also stiffening up the oil. The cooling of the charge can be shown by the indicator. It can be heard in the exhaust which, having less pressure, has less noise. And since there is less pressure at the end of the stroke it should be evident that there was less to work with during the stroke, unless some other reason than wall temperature difference exists. You are quite right that it is the aim of every designer to start with a high pressure and work it down to as low a point as possible before exhausting it, but no designer who knows his business will purposely reduce pressure by needless cooling before he is done working with the hot charge. No steam engine builder would think of putting a cooling jacket on his steam cylinder and it seems strange that gas engine builders will cool their cylinders needlessly low. That auxiliary valves are used to get rid of the gases quickly does not bear on the question. It is certainly right to throw away what cannot be used and to throw it away as quickly as possible.

Modern practice is much better in the matter of cooling temperatures than even a few years ago. There are several other things to be said in favor of hot walls. They mean faster heat radiation to get rid of the "excess" and so less radiator or cooling flanges needed. (That word "excess" is misleading. It does not mean that there is too much heat in the charge, but that the walls absorb more than they can stand and they must get rid of what they have absorbed in excess of their ability. Their ability is measured by the oil used, the likelihood of warping and the danger of their heat igniting the next charge too soon.) Heat radiates about as the square of the absolute temperature. So running the cylinder a little hotter permits a large reduction in cooling surface needed. This is along the line of reduced weight and cost. I look forward to the day when engines will be run much hotter than at present.

Your editorial on "Body Design" deserves a second reading. "Utility is the larger half of art" is a truth that cannot be told too often. Too many buyers in the past bought not to use but to show to their neighbors. No wonder second-hand rigs are cheap now. And no wonder that many people still hesitate about buying an automobile.

Reading Pa. CHARLES E. DURYEA.

ADDRESS OF FRENCH MAKERS

Editor THE AUTOMOBILE.

[2,035]—Will you please favor me with the addresses of the following French firms, or give me the name of some French publication which I can get in this country: Lion-Peugeot, De Dion-Bouton, Panhard & Levassor, Anzani, Gnome?

The above are the makers of the special long-stroke motors and aeronautical engines. J. D. MOONEY.

St. Paul, Minn.

The addresses which you request are as follows:

Lion-Peugeot, Les Fils de Peugeot Frères, 33 1-2 avenue de la Grande-Armée, Paris.

De Dion-Bouton, De Dion, Bouton et Cie., 36 Quai National, à Puteaux (Seine), Paris.

Panhard & Levassor, Société Anonyme Panhard et Levassor, 19 avenue d'Ivry, à Ivry (Seine), Paris.

Anzani, Anzani, 71 1-2 quai d'Asnières, Asnières, Seine.

Gnome, Société des Moteurs Gnome, 49 rue Lafitte (Seine), Paris.

In case you wish to look into the matter of aeronautical motors, and that only, it would be wise to consult all of the French constructors, although there are a number of firms in this country making a motor applicable to this work. However, we are adding a number of addresses of French motor constructors to your list. The additions are as follows:

Antoinette, Société Antoinette, 10 rue des Bas-Rogers, Puteaux, Seine.

Astsr, Société de Constructions Mecaniques, l'Aster, 74 rue de la Victoire, (Seine), Paris.

Buchet, Usines Buchet, 49 rue Greffulhe, Levallois-Perret, Seine.

Esnault-Psltsrie, Esnault-Pelterie, 49 rus de Silly, Billancourt, Seine.

Farcot, J.-A Farcot, 9 boulevard Denain, Paris.

Renault, Renault Frères, 139 rue du Point-du-Jour, Billancourt, Seine.

Sizaire & Naudin, Etablissment Sizaire et Naudin, 79 rue de Lourmel, Paris.

WHAT CAUSED MISSING

Editor THE AUTOMOBILE:

[2,036]—Thinking your readers might be interested in a puzzling case of missing fire, I send the following: I had just installed a magneto and overhauled my Haynes car. It worked finely for a time, but all at once began to miss fire on two cylinders. I went over the wiring and cleaned out the carbureter, but no improvement. Finally, while leaning over with head close to carbureter I heard a whirring sound, and traced it to a one-inch slit where the packing between cylinder and carbureter pipe had come out. This inlet, of course, spoiled the mixture.

Hoping this may be of service to some troubled motorist.

WILLIAM SEVERANCE.

Stanford, Ky.

PROGRESSIVE methods are bound to find an outlet, and the growth of the business of the Anderson Carriage Company, Detroit, Mich., makers of the Detroit electric carriages, is ample evidence of the support the buying public most heartily gives a well conducted enterprise. For 1910 the company proposes to extend the line, more than double the output, and introduce such refinements in point of detail as the past year's experience with more than a half a thousand cars would seem to warrant.

The title figure will afford something of an insight to the art side of the electric situation as it is coupled up to Detroit electrics, and it is needless to say that the output of this progressive company is garbed in the several very excellent designs of bodies in keeping with the requirements, and at the command of the patrons. The body situation, then, will not have to be discussed at great length, and it will be enough to point out that the line includes everything from the little "piano box" to the most luxurious type of town car.

A Regular in the Detroit Line.—The Model D chassis is shown in the lower illustration on this page with the battery divided in two sections of two trays each and located at front and hind end of the chassis, thus bringing the body in the mid position, which makes for easy riding, and places the battery where it may be examined readily, at will. The weight of the battery is distributed in such a way that half comes on each set of springs, and this is quite an important point, making the spring problem easy and reducing wear and tear on the car.

When the Model D car is fitted out as a brougham it presents a neat and distinctive appearance, rides remarkably well, and is an easy going car with a remarkable ability for mileage, according to experiences gained. Some of the leading specifications of this model are as follows:

Wheel base, 79 inches.
Tread, 51 inches.
Wheels, 32 inches front and rear.
*Tires, 32 x 3½ inch.
Battery, 24 cells, 13 M. V. size.
Speeds, five, graded to 5-8-13-17-22 miles per hour respectively.

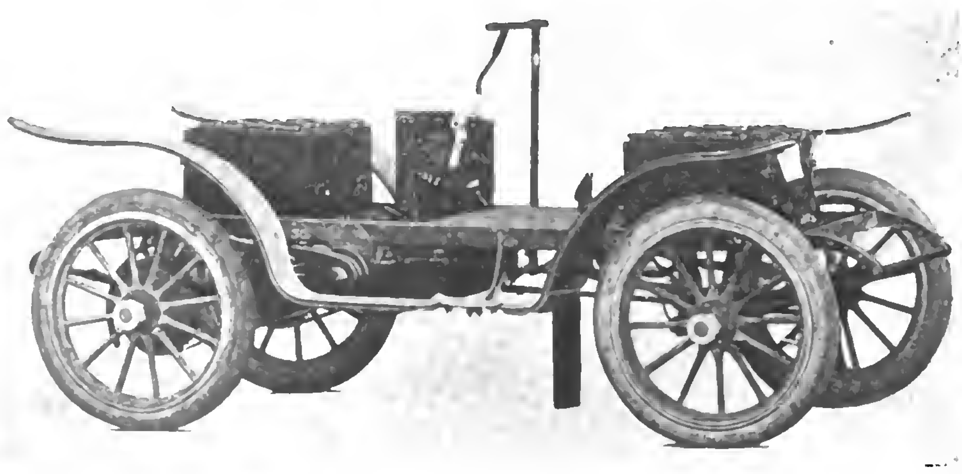
This car as a brougham weighs about 2,300 pounds, has a side lever steering gear, is equipped with two sets of brakes, one of which is on the motor and the other is on the rear wheels, of the internal expanding type.

The motor of Model D is of the enclosed type, series wound, and has a high torque characteristic, which assures the ability of the cars so fitted, will be maximum when it comes to hill climbing, soft going, and other unusual road conditions. Then, as will be well appreciated by those who may have given the matter thought, the speed of the car will be high when road conditions permit, which is to a certain extent an automatic condition.

The motor is of liberal rating, has a low temperature coefficient, will stand heavy overloading for a considerable period of time, and the commercial efficiency under average loading is very high indeed, thus insuring that the fixed losses are a minimum, while the high overloading ability is a guarantee that the copper losses are reduced to the lowest limit. These are all matters of the greatest moment to an owner of a car, and on account of the careful manner in which the electrical problems are worked out the battery "draft" is maintained at a low ebb and the radius of action is therefore on a very satisfactory basis.

Difference Between Now and Yesterday—Time was when electric carriages were not quite so satisfactory as was the wont, due to the relatively short distance that could be made on a single charge of the battery. The difference, which is now very great, when reference is made to mileage per charge of bat-

*Goodrich-Palmer web double tube clincher, 10 layer fabric.



Model D Chassis, Showing Equal Distribution of Battery Weight

Model D, 1910 Controller

tery, or better yet, per kilowatt of capacity of the same. In divers other ways the situation has undergone improvement, such as the controller, which is more simple and reliable.

But this same simplicity has been carried into the car as a whole, and by a process of elimination all the little sources of trouble have been removed. This is instanced in the rear axle for Model D car, to which is attached the distance members of the lattice form. The axle is fitted with Timken roller bearings, thus caring for friction and lateral thrust. The internal expanding brakes are of good diameter, and the shoes, which show on the axle, are faced with Raybestos, a fabric of asbestos interlaced with copper. This material is quite strong, having a tensile strength of about 2,800 pounds per square inch, and at 1,000 degrees Fahrenheit it is immune from trouble, while the coefficient of friction is better than .20 when the material is properly applied, as it is in this case.

Renold Silent Chain and Flexibility—An examination of the Model L type of motor shows more clearly than usual the aims of the designers to accomplish the main purpose, which is to assure that the mechanism of the transmission system will be flexible, efficient and durable. This particular example, with the covers removed, opens up to view the double reduction system, utilizing Renold silent chains to make the transmitting connection between the motor and the live rear axle.

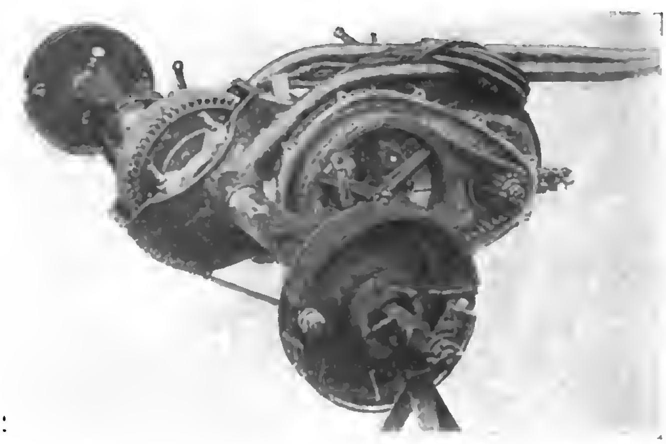
The end of the live shaft is exposed, showing a square, with a nut, castellated to accommodate cotter pins, and with the hubs of the rear wheels broached to fit tightly over the square shaft. Considering a long bearing, the results are very satisfactory. This view also presents the internal expanding brake shoes in such a way as to indicate great rigidity, which is essential to good work.

An Eye for Detail Makes for Success—Glancing over the cars in a general way at the plant of the maker discloses in a thousand ways the closest attention to detail. The batteries are received in the "green," and under the guidance of men of skill they are most carefully handled. The "trays," which hold the cells of battery, are made of selected grades of oak, properly seasoned, and so put together by dovetailing that they would stay in shape were no other fastenings used. The brass screws used to further bind the crates are countersunk, and the jars which hold the elements composing the cells of battery are so closely and properly nested that there is no likelihood of cell breakage, which form of difficulty was once so prevalent as to be a great nuisance and a source of considerable expense.

Motor Equipment, Model D, Detroit Electric

The electrical wiring is nicely done, the sizes of wire used being adequate to assure a minimum "drop," even under an excess draft from the battery as when the cars are accelerated on a grade under inferior road conditions. In a mechanical sense the cars are carefully constructed, using selected grades of material throughout, all fits are carefully made, involving suitable limits of tolerance, and of noise there is positively none.

In the steering gear all the links and levers are made of fine grades of steel, the shapes are such as to assure an adequate factor of safety, and the means for locking are standard in every way. Ball and socket universal joints are used in every case demanding them, and the bearing surfaces are so great, due to the use of large diameter balls, that wear is a minimum, yet even so, adjustment, to eliminate lost motion, may be made at will by the user without having to display a large measure of skill.



Silent Chain, Double Reduction Drive Used on Model L

POPULARITY OF ELECTRICS INCREASING

By W. C. Anderson, Pres. Anderson Carriage Co.

Enormous increase in the volume of business now being done by electric automobile manufacturers, certainly must be accepted as being first-class evidence of the degree of interest which the public is beginning to take in the electric automobile.

The utility of an electric car has never been as great in the past as it is to-day, and, therefore, it is bringing to the defense of the electric auto a class of well-posted buyers, who certainly do the industry great credit. To-day, the man who buys an electric in preference to any other style of propelled car, is not one who would either be considered as lacking in judgment.

Originally electric autos, were very much like they say religion is, namely, mostly indulged in by the ladies, and while there has not been a spiritual revival possibly among the men, there has certainly been an electrical revival, and the number of converts who are now showing their confidence in the permanency of the electric auto and its desirability, is really beyond the belief of a person who has not carefully noted this fact. As surely as every effect has a cause in any other phase of life, the same is true in the electric automobile. Its popularity will widen with the future of its development because of the natural love people have for a clean method, and a safe method, of being conveyed. So often it is better expressed by the people who come to buy an electric when they make the remark, that they want something that is "sane and simple," and therefore they investigate the merits of an electric car. The larger mileage has not escaped the notice of those who contemplate the purchase of some kind of an auto. Judging from demands, the interest of the public in the electric car cannot be overestimated.

UNDER the corporate name of the Metzger Motor Car Company, Byron F. Everitt, William Kelly and William E. Metzger will soon place upon the market a new car to be known as the Everitt Thirty. These men, it will be remembered, in company with W. E. Flanders, formed the E-M-F company, selling a car of that name. This concern was purchased on May 1 by the Studebaker Automobile Company, Mr. Flanders remaining as general manager. All of the men are well known in the trade.

The car will be a four-cylinder machine of the shaft driven type, designed by Mr. Kelly. This will be equipped with but two forms of body, a runabout and a five-passenger touring car. The latter, shown at the head of this article, is seen to possess pleasing lines. The wheelbase is long, the wheels are large, and in combination with a good spring suspension, should result in a very easy riding car. The spring suspension is seen to be: semi-elliptic springs in front and full elliptic scroll-ended springs in the rear. The former are fixed at the front end and shackeled at the back, while the rear springs are attached to the under side of the frame, which is upswept back of the tonneau entrance for this purpose. The combination gives a low center of gravity, and a low step, without losing anything from the very important clearance. Not only is the rear end upswept, but the frame has another drop just forward of the dashboard, making it what is known as a "double drop" frame. This is the form that has heen adopted by the best foreign makers, so that its use in a moderate - priced domestic car represents an unusual value, and one not heretofore offered in this class of car.

The power unit is carried well back from the front end of the chassis, rather farther than usual, in fact, the front line of the radiator being behind the front axle. The latter is of the popular I-section, and the material, steel. Spring seats are forged integral.

Pressed steel is used very freely throughout. The fenders, fender supports, steps, and many other parts are pressed from this material, which offers at one and the same time strength and light weight, an unusual combination. The fenders are both carried down to the frame on the inside, which enclosure prevents any mud or dirt from the road splashing up on the occupants.

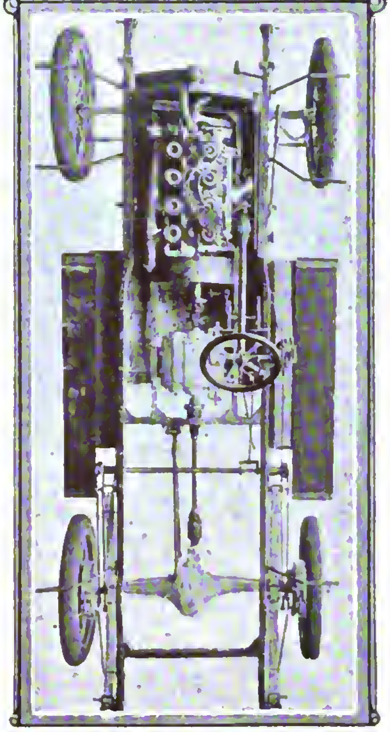
Back of a radiator of the Mercedes type, under a long hood, is located the engine and clutch. Behind the dashboard a liberal space is allowed for the driver's foot room, this being a point in the comfort of the driver. The steering wheel is given a large rake, which lends to the whole side view of the car a low, fast appearance, not at all distasteful. A large diameter steering wheel affords the driver excellent control over the car regardless of whether he uses one hand or both. Below the wheel, on the driver's left, are placed the spark and throttle levers.

Two foot pedals of the piano type are provided for control purposes, both working on the push forward principle. Besides these, there is a foot accelerator for the sudden control of the car in heavy traffic, such as in the crowded city streets, or in an emergency of any kind. The side levers are short, the emergency brake lever being placed on the outside. This is held in any desired position by a ratchet on the under side of the quadrant bar, which is notched for this purpose. The inner lever is the change speed operating means, and is the shorter of the two. While the new car has not heen placed on the market, several cars have been built and tried out on the Detroit streets.

About thirty days ago the company purchased the factory of the Jacob Meier Company, trunk manufacturers, located at Milwaukee avenue and the Grand Trunk Railroad, as shown by the cut on this page. The plans call for the manufacture of 5,000 cars during 1910.

Large and Commodious Plant in Detroit to be Occupied by Metzger Motor Car Company

What the K-10 Pullman Is Like



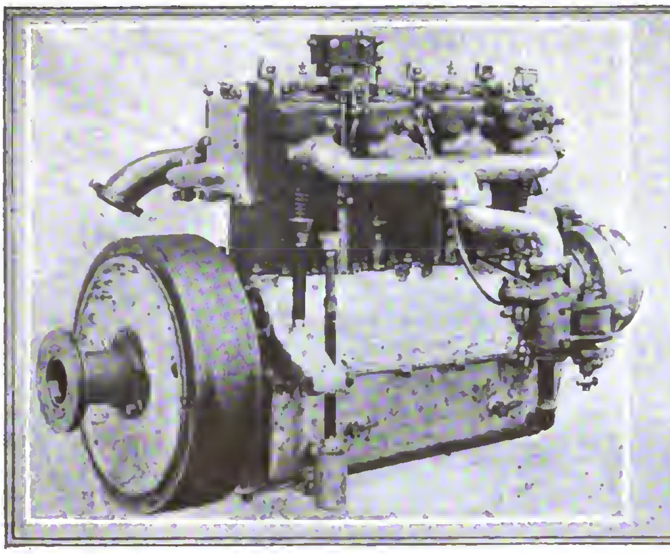
FOUR models, in many styles of body, and with three differing sizes of engines will constitute the output of the York Motor Car Company, York, Pa., for the coming season. Of these, the model bearing the mark K-10 will be the leader, and since the construction of the others follow this one in nearly every particular, it will be sufficient to describe that. The four models are: K-10, a four-cylinder car, to be had with runabout, baby tonneau, or five-passenger touring car bodies; 4-40, a four-cylinder car of greater power and speed, which is turned out with but one body, a gentleman's roadster; M, a touring car with a large and powerful motor; and finally, a new car, to be known as Model O, the details of which are not ready yet. This latter will be a high-class, light car, to sell at a lower price than Model K-10.

Probably the most interesting part of the car is the motor. This is of the four-cylinder type, with cylinders cast individually. Each cylinder has a widefaced flange cast on each end, these being machined so as to fit together. Then, in assembling, the adjacent flanges are bolted together, making the power plant as a unit. It is argued in favor of this construction that it has all of the advantages of the block construction with none of its disadvantages. In addition, this method allows of the use of five bearings on the crankshaft. This makes the shaft very stiff and strong, since the power impulse from each cylinder is taken by a pair of bearings, equally spaced on each side. Not only is rigidity of the shaft itself gained in this way, but the danger of lack of alignment is reduced to a minimum, and lubrication is improved.

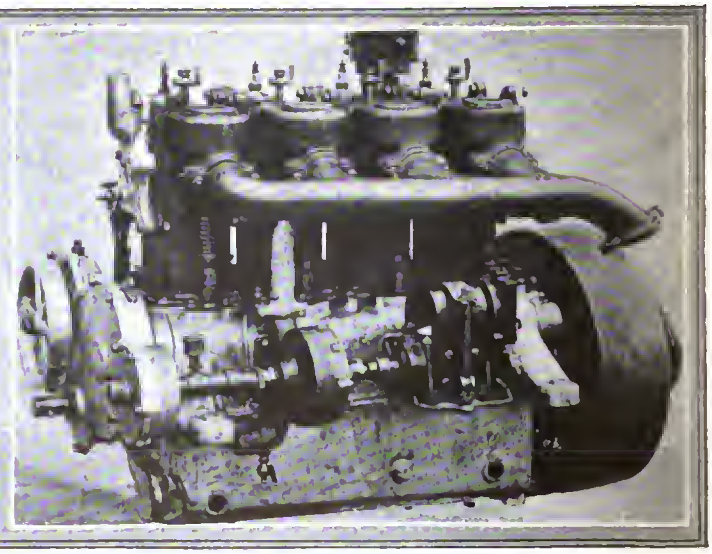
Cylinder Dimensions Increased—The size of the cylinders has been changed over that of last year, that is, the stroke has. The sizes now are 4½-inch bore by 4¾-inch stroke. In the lengthening of the stroke is to be seen the working out of the most modern tendency in engine construction, namely, the leaning toward long strokes. While this particular engine is not unusually long, the ratio being but 1 to 1.05, it denotes the movement now being made to take advantage of the superior power afforded by the "long" motor. The valve sizes have been increased, not only to care for the additional cylinder capacity, but still more than that, to allow of a better running, higher powered engine. So it is that, although the bore is not changed, and consequently the power rating by formula would not change, the output of this motor has been increased until it actually develops more than 35 horsepower on the test block. For this reason the company will call the engine a 35-horsepower unit.

Other details of the motor remain the same as in previous years. These include the well-known T-head cylinder form, with valves located on opposite sides. This symmetrical construction results in the placing of the inlet on the right side and the exhaust on the left. The right-hand placing of the inlet and carbureter puts this important adjunct where it is very convenient to the driver for adjustment or repair. Similarly, it takes the heated exhaust pipes out of the way of ordinary roadside work. The valves are located high up in valve pockets, which are well water-jacketed. The large flanges at the ends of the cylinders allow of the use of unusually large core prints at that point, which results in more accurately located cores, and also allows of the more complete removal of the core sand. Both points conduce to better cylinders. The same opening is used as the basis of the water circulating system, the pump feeding the liquid into the rear or hottest cylinder, from which it works its way forward through the interior of the cylinder water jackets to the front cylinder, the core hole cover plate there carrying an upward extension in the form of a pipe, to which the hose from the radiator attaches. This makes the system very simple.

Ignition System Most Complete—To insure perfect ignition, insofar as it is possible to have it perfect, two separate and distinct methods of firing the charge are fitted to the car, either one being complete in itself and self-contained. The source of current for the one is a high tension Bosch magneto, while batteries, acting through a single coil and distributor, furnish the



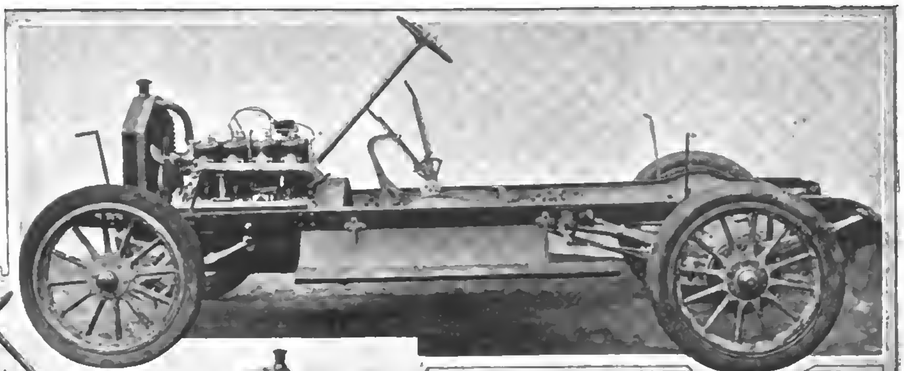
Inlet Side of Motor Shows Carbureter to Advantage



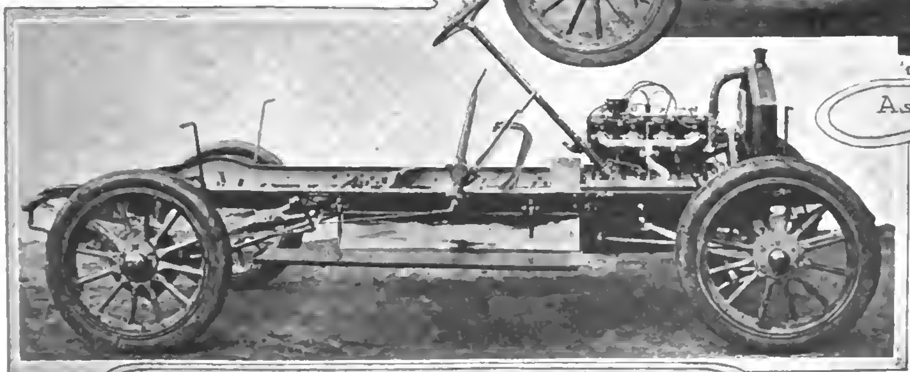
Accessories Are Grouped on the Exhaust Side alternate. The plugs for the magneto set are located in the top of the valve caps, over the inlet valves, while those for the battery-distributor system are placed in the side of the combustion chamber, projecting just above the inlet pipe.

One very marked feature of the engine is the oiling arrangement, which is distinctive. This is so designed as to furnish perfect lubrication at all times and under all weather conditions, and also to insure a continuous, perfect level, regardless of engine speed. The system includes an eccentric-driven pump located on the rear of the subbase, which receives the oil from the lower compartments of the base and delivers it to the upper compartments, provided wtih reservoirs. From these the oil is delivered to the base proper, where the splash lubrication takes place. The height of the oil in this base is controlled by eccentric valves, with stems extending outside of the base and with hands pointing to a dial marked in spaces one-fourth of an inch apart. The oil is raised or lowered by moving the hands. In other words, this is splash lubrication, with an oil reservoir in the bottom of the engine base and with eccentric pumps to raise it to the splash lubrication level.

Frame of Pressed Steel Shows Merit—The alloy steel frame of channel section with the open side turned in, shows a number of sterling features. The forward portion is narrowed by two inches to give a large steering lock. The rear end is arched over the rear axle, so as to provide



As the K-10 Pullman Appears from the Left.



Right Side of Pullman K-10 Chassis

plenty of clearance for the rising and falling action of the rear axle and springs when surmounting an obstacle. The frame has been lengthened over last year by 7 inches. This makes the wheelbase 112 inches and allows of the use of a more commodious body than before. Both front and rear springs are semi-elliptic, fixed at the front end and shackeled at the rear. The front axle is an I-section, drop-forged, while the rear axle is of the full floating type, mounted upon Timken bearings. The brakes are mounted on the rear wheels and are of two types, internal expanding and external contracting. These are of large diameter, lined with removable heatproof lining, and operate through equalizing devices, which insure an equal pull.

Almost every part of the car is now made in the Pullman factory, this including axles, steering gears, bodies, upholstery work, tops, all sheet metal work, as well as the more usual engine and transmission. This is a point well worth consideration, for it means that in case of trouble, spare and repair parts can be shipped instantly, which is not the case with an assembled car. The equipment of the cars is very complete. The factory figures for the 1910 output show that 2,000 cars will be completed, these being divided over the four models.

The crankcase is in two parts, the upper and the lower. Both of them partake of the shape of a box, the upper half being of a tapering section, while the lower is more nearly square. The material is aluminum, and it is heavily ribbed for strength. All of the accessories but the carbureter are grouped on the left or exhaust side. The shaft on this side, for the purpose of driving them, is jointed in several places so that any one accessory may be removed at will, without disturbing the others. The centrifugal pump is nearest to the front, being located midway between the first and second cylinders. The magneto is located farther back, being placed opposite the last cylinder. It is strap-held in place, a single bolt with a pivot at the bottom holding it. By loosening the nut, the bolt may be revolved out of the way, and the magneto picked right out.

CLASSIFICATION OF GASOLINE FRACTIONS

Generally, automobile fuel, which is in liquid form, is capable of classification, in the manner as follows:

(a) Olefiant hydrocarbons;
(b) Aromatic hydrocarbons;
(c) Alcohols;
(d) Combinations of the three.

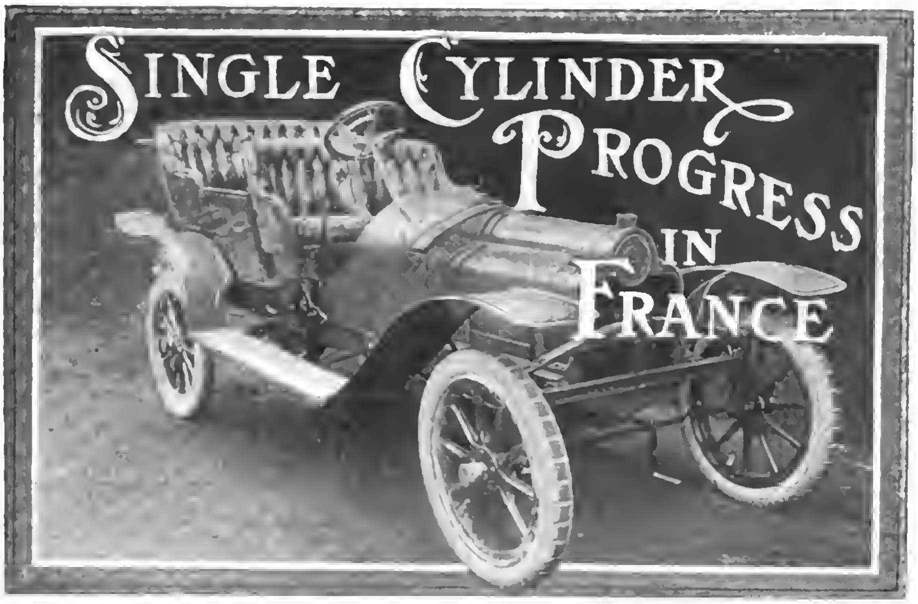
The olefiant class belongs to the series which form, or produce an oil; specifically designated as colorless, gaseous hydrocarbons called ethylene.

The formula of ethylene is C_2H_4, and the compound may be produced by the action of concentrated sulphuric acid on alcohol. It is an unsaturated compound and combines directly with chlorine and bromine, to form oily liquids (Dutch liquids) hence the name, "olefiant." The same compound is also called ethene, elayl, and formerly it was known as bicarbureted hydrogen. The aromatic class include a long series of hydrocarbons such as may be derived from benzine, the formula for which is C_6H_6.

SOUTHERNERS INVESTIGATE GOOD ROADS

Providence, R. I., Sept. 27—The party of Southerners, who, as the guests of B. F. Yoakum, of the Rock Island-Frisco railroad, are touring New England to study its systems of roads, arrived here Sunday in four Packard cars, in the midst of a driving down-pour of rain. The party has now been ten days on the road. They came down from Boston by way of Plymouth and Fall River. Poor roads were encountered between Plymouth and Fair Haven, and the machines skidded badly in the mud between New Bedford and Fall River. There were no mishaps, however, and the party was not forced to stop at any time.

The party consists of representatives from Louisiana, Arkansas, Texas and Oklahoma. Mr. Yoakum, who is an enthusiast on the subject of good roads, suggested the tour in a speech at Shawnee, Okla., August 17, and is paying the expenses. The state road officials have co-operated by giving frequent talks on the construction of the roads met on the tour. The sustained interest has surprised every member of the party.



PARIS, Sept. 24—The high price of gasoline, together with special methods of taxation and, in a smaller degree, the state of the highways, have all tended to the development and popularity of the one-lunger type of car in France. Conditions are so different in America that doubtless the one-lunger will never attain the same importance as in France. It is nevertheless interesting to note what has been done by specialists on this side of the water.

The first rule that was laid down was that the single-cylinder car must look like a four. This was not difficult to arrive at, and has been so generally copied that from an examination of the lines only it would be impossible to say whether the bonnet housed a one, two or four-cylinder engine. Frequently to aid in the deception without losing too much space the gasoline and lubricating oil tanks are fitted on the dash.

The next point was to make the engine so silent and easy running that it would be impossible for the ordinary man to declare how many cylinders were at work. This was a more difficult problem, as was shown by the fact that many a car from a good factory looked all right when it was motionless, but revealed its number of lungs as soon as the starting crank was pulled over. Such improvement has been made during the past year or two that there are now two or three makes of cars with only one cylinder that can be throttled down so low and made to turn so quietly that only an expert placed six feet away could certify to the number of cylinders. It is understood, of course, that the type of engine can be detected if it is raced, but it is a fact that if throttled down to run at the slowest speed such engines as the latest models of Sizaire-Naudin, De Dion and others that might be mentioned are not only so quiet that they cannot be heard a few feet away, but would put to shame some fours which would object to being called bad. On steady running, too, the difference between the one and the four has been made so slight as to be hardly noticeable; and it is only when it comes to varied work with much gear changing that the real inferiority is felt.

Taking the Sizaire-Naudin as one of the best examples in the one-lunger class, we find a vertical cylinder of 4 7-10 by 5 1-10 inches bore and stroke, with superimposed valves, the exhaust being operated from below and the intake from overhead. In accordance with modern practice, the valves have a large area even on the standard models, while on the semi-racing and full racing models it reaches the abnormal. There is nothing of special interest about the exhaust, but the operation of the intake, which is immediately above it, is of greater interest. The lift of the valve is varied by the displacement of a helicoidal cam, operated from the lever on the steering wheel. There is no control direct on the carbureter, the amount of lift of the valve of course regulating the amount of mixture that can be aspired. The rocker arm is a short lever with spherical ends, one of which fits onto the projecting stem of the inlet valve, while the other receives the end of the vertical push rod. It pivots on a crossbearing above its center, against which it is pushed by both the valve stem and the push rod. A wrench allows the entire valve-operating mechanism to be dismounted in a few seconds.

A light steel piston, with only two compression rings at the top and a guiding ring at the base, is employed. The piston is of more than usual length. Like the piston, the connecting rod is made as light as possible consistent with strength. Compression is high and very heavy internal and external flywheels are empolyed. The carbureter is placed very close to the cylinder walls—in fact almost touching them—in order to obtain all necessary heat without jacketing. It is an ordinary float feed type, with flow from the dashboard tank by gravity, and the air inlet at the base of a venturi tube, below the single jet nozzle. The tube mounts straight to the top of the cylinder, gradually widening as it mounts. The additional air inlet is almost direct over the inlet valve, the air being admitted through an automatic valve.

Water cooling is by thermo-syphon, the flow being through a plain copper tube radiator, with a large circular water tank immediately back of the head of the radiator. For the size of

Unusually simple steering gear — **Dashboard, lubricator, and single pedal** — **Plate clutch and spring**

Some of the Mechanical Details of the Single-Cylinder 12-Horsepower Sizaire-Naudin Car, Shown In Title

the motor the water pipes are of large diameter and are altogether devoid of bends, thus allowing a flow of water without any obstruction whatever. Ignition is by high-tension magneto with timing gears exposed. Provision is made for double ignition, but it is very rarely indeed that it is fitted. The exhaust port is of very large diameter, as is also the exhaust pipe. The use of a long and efficient type of muffler makes the exhaust absolutely noiseless. The absence of chug-chugging from the exhaust is somewhat remarkable, though there is nothing secret in the manner in which this silence is obtained, it being no more difficult to fit an efficient muffler on a one-lunger than on an eight-cylinder engine.

Lubrication for the motor is by splash, there being a couple of drips on the dash, one leading to the engine and the other to the rear axle. Some of the other features of the car are a transverse, inverted, semi-elliptic spring in front and shaft drive with differential and change speed mechanism combined in the rear axle, with direct drive on all three speeds.

A feature of unusual interest is presented in the steering gear. This consists of a coarse pitch worm of great depth, into which a hardened finger is set. When the worm is rotated in the usual manner, the finger is constrained to move, but being made a part of the steering shaft, must move in the arc of a circle.

Large Water Tank Is Hung on the Radiator

FRENCH COMPETITION FOR AERO MOTORS

Paris, Sept. 25—The light-weight motor, developing great power and being absolutely regular in its running, being at present the greatest need in the aviation world, the Automobile Club of France announces another motor competition similar to the one held in its laboratory last spring.

Several lessons learned in the first event are being put to profit. Thus instead of a minimum and maximum horsepower being given, the weight of the motors only is limited. Under the old Gordon Bennett rules, when the chassis weight was fixed at 1,000 kilos it was found possible to increase the power from about 25 to 120; it is believed that by fixing a weight limit in the same way for engines the power developed can be increased considerably.

The weight limit is 330 pounds per motor, complete with everything necessary for running. Fuel allowance is 13 ounces of gasoline and 2 ounces of lubricating oil per horsepower-hour. If this amount is exceeded the weight of the excess will be added to the total weight of the motor; if the consumption is less than this the weight of the difference will be deducted from the weight of the engine. A three hours' test will be made under full load. No engine can be classed which weighs more than 8 4-5 pounds per horsepower.

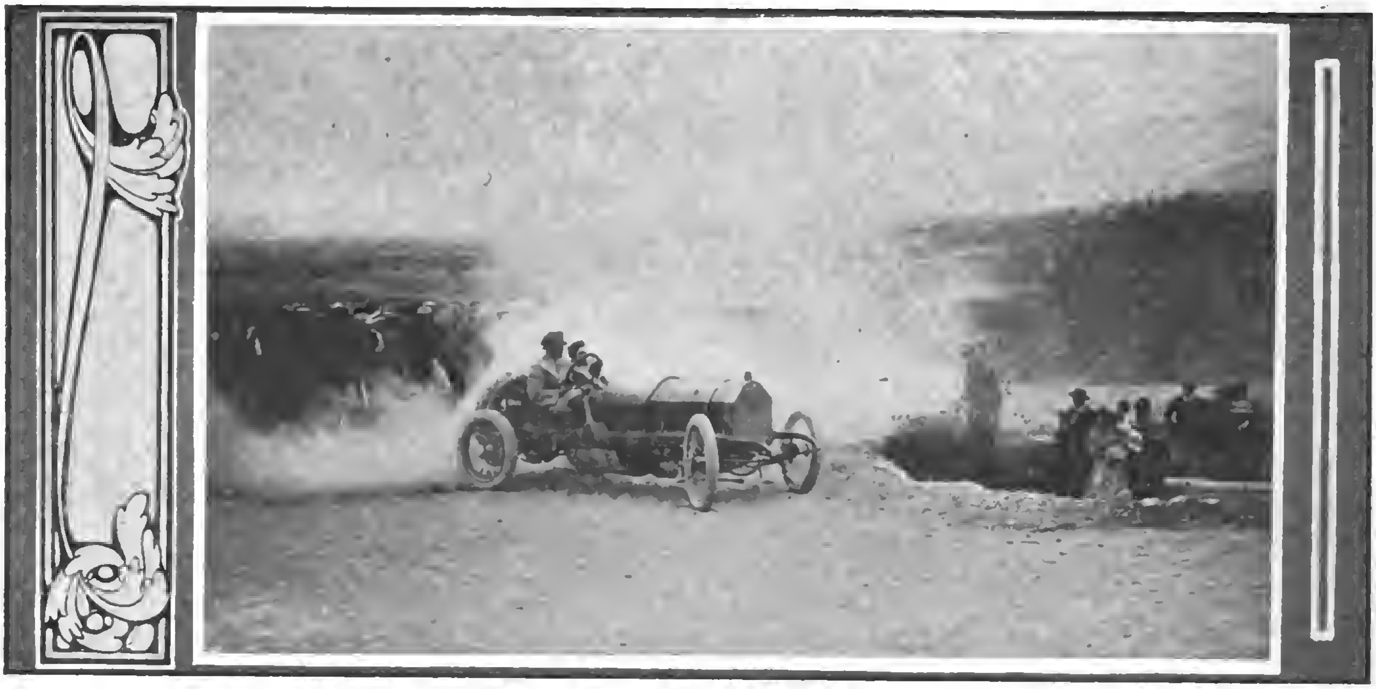
It will be endeavored to make the conditions of the test approximate as near as possible those under which an engine has to work when on an aeroplane. Thus, an air-cooled motor benefiting by a blast of air from the propeller when on a flying machine, will be allowed to use a fan, the weight of which will not be taken; the power necessary to drive the fan will be added to the effective power of the engine.

Considering the disadvantages under which water-cooled engines are placed during a bench test, a radiator, water tank and fan will not be weighed. All piping, as well as the water pump will be included in the weight of the motor. In place of the ignored cooling organs each motor will have to bear a supplement in the shape of 1 1-10 pounds per horsepower, according to the average power developed during the three hours' test. Piping will be fitted to carry the exhaust out of the testing room, but will not be included in the weight of the engine.

Since the last motor test the suggestion has been made that the engines should be mounted on a spring base. It is considered, however, that as the framework of an aeroplane has very little elasticity, this should not be allowed. The suggestion has also been made that the engine should be mounted on an aeroplane, but this has also been rejected on the ground that the aeroplane attached to the floor or a bench in the testing room would not be in the same conditions as when in the air. The flexibility of the frame, in addition, might cause the breakage of the crankshaft or the rupture of the universal joint between the engine and the brake.

The tests will be held during the month of December at the Automobile Club laboratory, near Paris. Entries are received at the rate of $20 per motor. Out of the subvention offered by the Minister of Public Works a prize of $200 and two prizes of $100 each are offered.

Entries for the light-weight motor competition are not likely to be lacking, for there are at least a score of firms that have studied this problem. Brasier, admitted one of the finest motor designers in France, has a four-cylinder aero motor ready to put on the market; Bayard-Clement has a new light-weight six; Gabriel Voisin has just designed a simple light-weight four; Buchet has produced a six; Renault, in addition to the eight-cylinder air-cooled model has an interesting four for aeroplane work, and Anzani has a new four with the cylinders placed in V. These are all engines that have not yet been fitted to any aeroplane. The number of those in daily use for flying machines is very much greater.



One of the Difficult and Trying Turns in the 13½-Mile Course Up Mont Ventoux

HISTORIC CLIMB OF MONT VENTOUX

Avignon, France, Sept. 24—Mont Ventoux, the longest and most difficult hill-climbing course in Europe, was again conquered in record-breaking time. Between the little village of Bedoin and the observatory on the summit lie 21.8 kilometers (13.5 miles) of narrow road with an average grade of 9 per cent. As in last year's meet the hero was Bablot, driving a Brasier. He drove his car up the steep and winding course, through a fog which made it impossible to see twenty yards ahead, in the remarkable time of 18:41. Bablot had the advantage of an intimate knowledge of the course, and without goggles, he took the dangerous turns at full speed. Pierron with the Motobloc took second in the same class with the time of 19:42, feeling the handicap of the fog much more than his speedy rival. Lochner with an Opel, Tangazzi with a Lancia and Ceirano with a Scat each won their respective classes. The voiturette trials on the first day resulted in a double victory for the Hispano-Suiza, a Spanish car, and Bablot also scored with a small Brasier. It is noteworthy that both this year and last Bablot succeeded in breaking the record in spite of unfavorable weather conditions, and the French sportsmen are eagerly looking forward to next year in hope that, at last, he will be able to show his best speed.

FRANCE MAY BECOME PARSIMONIOUS

Paris, Sept. 24—Automobile tourists to France, who have run over the sandpapered roads of the republic and left a fertile stream of dollars at hotels and holiday resorts, without ever being called upon to pay for the use of the highways, are now about to learn that there is a revenue officer in this land of travel. Next year's budget proposals provide for the taxation of automobiles brought into France for temporary use. It is not decided what the tax will be, the official statement being that it shall be in proportion to the length of stay, and on the same ratio as is paid by home cars. The proposal is not received with anything like joy, even by the natives, for though the foreign visitors may do a little to scratch the fine surface off the roads, it is calculated that the money they bring in is worth far more than the damage they do.

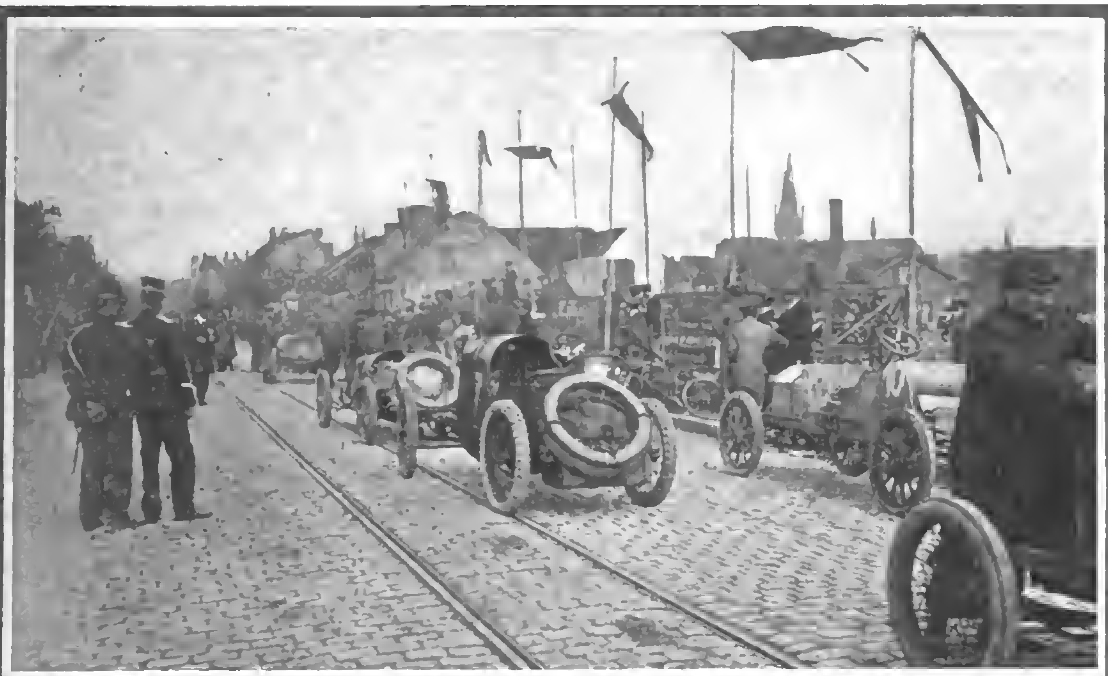
But the home autoist has not escaped attention. If he is the possessor of a car modestly rated at less than 10-horsepower he will not be called upon to open his purse strings any wider. If he has a more powerful vehicle the increase may be as high as 42 per cent. He must pay a fixed tax of $8 for a two-seated car and $15 for a four-seated vehicle, if he habits any town other than Paris, in addition to a tax per horsepower increasing from $1 per horsepower up to 10 horsepower until it reaches $6 for every horsepower above the eighty-first. If the owner lives in Paris he will have the pleasure of contributing an almost equal amount to the city authorities in addition to his State tax.

LONDON POLICE REGULATE MOTORBUSES

London, Sept. 25—The new police regulations for motorbuses show several important changes, especially in limitations of weight and speed, tire section, etc. The maximum weight unloaded is specified at 3½ tons, with an option of 6 tons loaded, in which case 4 tons must be on the rear axle and 2 tons on the front axle. The maximum number of passengers is 16 inside and 18 outside, and in estimating loaded weight 140 pounds must be allowed for each passenger, as well as the driver and conductor. The total length of the vehicle must not exceed 23 feet, nor its breadth 7 feet 2 inches; the clearance between the front and rear axles must be a minimum of 10 inches loaded. Tires must be of resilient material. All 'buses must be so geared that their maximum speed shall not be greater than 12 miles an hour, or else be fitted with a device to give an audible warning as long as that rate of speed is exceeded.

MAINTENANCE COST OF LONDON TAXICABS

Figures showing the number and cost of replacements on the taxicabs in use in London have been collected by *Motor Traction*, an English magazine principally devoted to commercial vehicles. The most valuable are those pertaining to the 10-12-horsepower two-cylinder Unic cabs, which have been in use for three years. That part of the mechanism of these cabs which wears out first is the second speed countershaft gear. This must be renewed after 10,000 miles, at a cost of $9. The sliding member of the change-gear lasts from eighteen months to two years; it costs $24, with its two pinions. The bevel driving pinion lasts 18,000 miles, and entails an expense of $10 for renewal. All the other gear wheels of the cabs were in good condition, without having been renewed, after three years' running. The total expense for replacements averaged $.003 per mile.



Contenders on the Course at Ostend, Where the Little Cars Provided an Exciting and Fast Race

FRENCH VOITURETTES RACE AT OSTEND

Ostend, Belgium, Sept. 18—The Coupe des Voiturettes, the only road race held this year, proved a complete success, and the absence of the big racers was scarcely noticed. In fact, the little cars are as fast as the big ones were two years ago, as everyone had to admit when Collomb made the fastest lap at the rate of 62 miles an hour. Lion-Peugeot added another to its long string of victories by taking first place. Giuppone was the winning pilot. Thomas, on the Le Gui, took second, being the only other contestant to finish the 248.6 miles called for. Collomb on the Corre-La Licorne took the lead from Giuppone on the third lap and held it till the sixth, when his car overturned. All contestants except Giuppone and Thomas dropped out before the tenth lap. Lormelle, driving a two-cycle Darras, was one of the last to quit, his trouble being a broken wheel. Giuppone's time was 4:33:28, an average of 54.4 miles an hour. The other two Lion-Peugeots had trouble early; Boillot cracked a cylinder and Goux burst a tire after he had used up all his spares. The race was characterized by the usual good management and was a great success as a sporting event.

EX-CHAIRMAN THOMPSON IN GERMANY

Jefferson de Mont Thompson, ex-chairman of the A. A. A. racing board and Vanderbilt cup commission, has been spending most of his summer in German touring. In the course of a long article, the Dresden *Daily Gazette* quotes Mr. Thompson on the Long Island Motor Parkway, and then continues:

Mr. Thompson for the past three years has almost continually been touring Europe en automobile, inspecting road conditions and other matters of interest to automobilists. His judgment on the Saxon roads will be read with pleasure, coming as it does from such a source. "I find the Saxon roads," he informed us, "by far the best in Germany, if not in all Europe. The materials to hand in this country are particularly adapted to road-making requirements, and the yellowish gravel used in Saxony is now recognized as the best material known to exist. I have been profoundly impressed by the superb engineering that is everywhere visible as I motor through Saxony, up finely graded hills and over perfectly smooth mountain roads."

Mr. Thompson also had many pleasant things to say of the courtesy and consideration which he invariably meets with now at the hands of German customs officials and other frontier officers. Up to eight or nine years ago, he said, conditions were very different, and an American tourist entered Germany in some trepidation. Now he comes in the full conviction that he is welcome, and as a consequence American tourist traffic, particularly en automobile, is almost doubling every year. "I always recommend the German tour to my American friends," continued our informant, "and I frequently meet over here acquaintances whom I previously advised to give the Fatherland a trial. I like to advertise the qualities of Germany everywhere I go because I get along so extremely well with the German people and German customs."

Mr. Thompson is one of the founders of the Aero Club of America and is a delegate to the aeronautical international convention to be held in Italy during next October. "We in America," he said, "are greatly interested in aviation, and at present there are six members of our club who fly at least as well as the brothers Wright."

In conclusion Mr. Thompson told our representative that this is his eleventh summer as an automobile tourist in Europe, and, "although I fear you will hardly believe me, I have never had an accident of any kind."

According to another paragraph in the Dresden paper, Mr. and Mrs. Thompson were entertained by Consul-General T. St. John Gaffney and Mrs. Gaffney, who afterwards accompanied them on an automobile trip through Saxon Switzerland.

WHY MADRID IS DISCARDING AUTOS

Vice-Consul Maddin Summers, of Madrid, furnishes the following information concerning the use of automobiles and carriages in the capital of Spain:

For the last four or five years the use of automobiles in Madrid has almost overshadowed the carriage trade. Autos became fashionable, both for excursion purposes and for use in the city. It was argued that their running expenses would be less than the maintenance of horses and carriages. This, however, has proved a mistake, as far as Madrid is concerned, as repairs and separate pieces are very expensive, owing to high duties, freight, commission, transportation, etc., very much the greater number of the machines being of foreign manufacture. Then the price of gasoline is double what it is in France. The consequence is an automobile crisis, and many persons are selling their machines very cheaply to get rid of them, while the carriage and horse trade, on the other hand, is looking up.

There are practically no American automobiles and few carriages in Madrid, for the reason that intending buyers want to see the machine or carriage before purchasing, so that they may know exactly what they are buying. The principal foreign automobile manufacturers have branch houses here, with machines to show interested persons. They also have on hand the repair parts, etc., so that the purchaser knows what he is buying.

Santos-Dumont in His Record-Breaking Flight at St. Cyr, France, Making Speed of 56 Miles per Hour

SPEED RECORDS ANNIHILATED BY SANTOS-DUMONT IN FRANCE

PARIS, Sept. 25—Maurice Guffroy and his attendant mechanics were working in their aeroplane shed by the side of the "Salt Hole," a few miles out of Versailles, when the noise of an open exhaust attracted their attention. The sound did not come from the highway, which runs by the shed, but was furnished by a motor up aloft and advancing rapidly over the plateau. A few minutes later and the aeroplane had settled down, Santos-Dumont had stepped out and Guffroy had lost his bet.

A few months ago, Guffroy, the Rep pilot, and Santos-Dumont, the steersman of his own aeroplanes, each built sheds twenty miles to the west of Paris, Santos-Dumont selecting a spot in the valley near the town of St. Cyr, and the Rep pilot pitching on a plateau six miles away. Santos-Dumont made a bet that he would pay a visit to Guffroy in his aeroplane.

Messrs. Santos-Dumont, Darracq and Ribbeyrolles

Months passed and the affair seemed to be forgotten, for the diminutive Santos-Dumont flyer had given but indifferent results at the trials. Then a new motor was procured—a simple two-cylinder, horizontal, developing 30 horsepower and weighing 110 pounds—which was found to be so satisfactory that after one preliminary trial the aeroplane was steered direct for the Salt Hole, six miles away, high up on the hill.

Santos-Dumont rose after running less than thirty yards on the ground, and with a favoring breeze behind traveled at the rate of more than fifty miles an hour. He had to rise high, almost two hundred feet above the ground, in order to clear the telegraph wires and tall trees. Seven minutes later he had settled down without breaking a spar, having accomplished a high speed cross-country flight with the smallest aeroplane in existence.

The Santos-Dumont monoplane is only 20 feet from tip to tip, compared with almost twice that area on the majority of monoplanes. It has a light bamboo backbone, at the extremity of which is a tail and the rear rudders, and has the general appearance of a large dragon fly. The motor is a two-cylinder opposed horizontal of 5.12 by 4.73 inches bore and stroke, without flywheel, and of very simple, even ordinary design. It is the first of this type that has been built at the Darracq factory, but has given such satisfaction that a series will be commenced.

While winning his bet with Maurice Guffroy, the Brazilian aviator won another with Henry Farman, who had declared that an aeroplane of such small dimensions would never be able to fly. It has not only flown, but proved itself very much faster than any other machine in France. It is believed that an aeroplane of this type could be built for $1,000. Santos-Dumont declares that he has no intention of entering the business, but that anybody is at liberty to copy his design who desires to do so and build for themselves. He is satisfied to have created the "baby" type of aeroplane.

Santos-Dumont Also Gets a New Starting Record

Not satisfied with making a cross country trip of six miles on the smallest aeroplane in existence, Santos-Dumont returned from Buc to his shed at Saint-Cyr, landing within a few feet of his own doorway. After the trip out, the aeroplane passed the night in the Rep shed on the Buc plateau; the next afternoon the areoplane was brought out, the motor started and the home trip across the open fields, woods and streams was commenced. Seven minutes were occupied in making the journey, the increased length of time being accounted for by the presence of a brisk head wind.

The next exploit was to beat the starting record established by Glenn H. Curtiss in Italy. This Santos-Dumont succeeded in doing, getting into the air in 6 1-5 seconds, after a run of 229 feet on the ground. Curtiss had only been able to rise after 8 seconds, during which time he covered 246 feet before getting clear.

The attempt was disappointing to the aviator, for he had imagined that he could get away in half the distance necessary for the Curtiss machine, that is in a little over one hundred feet. Several attempts were made, one of them being on the highway, but it was not possible to get a shorter time than 6 1-5 seconds. It will be interesting now to watch the machine in a speed test round a course such as that at Rheims. It appears to be faster than either the Curtiss or the Bleriot flyers, but estimates even of experts are apt to be so far from the reality that an officially timed test should be made. The aeroplane, which is only 30 square feet in area, is fitted with a Darracq two-cylinder horizontal water-cooled motor, developing 30 horsepower for a weight of 110 pounds.

LATHAM FLIES ACROSS BERLIN

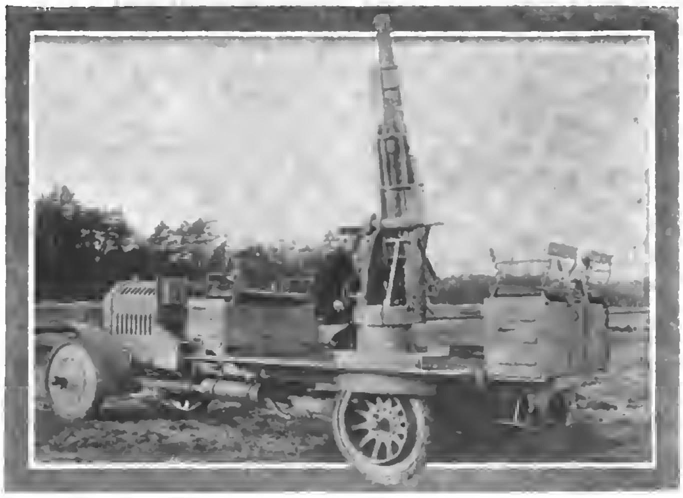
Berlin, Sept. 27—Hubert Latham to-day made a brilliant flight across the city from the Tempelhof Field to the aviation field at Johannisthal. The distance travelled was about ten kilometers and the time seven minutes. The wind was favorable, and Latham soared for most of the distance at a height of 100 meters. His machine was an Antoinette monoplane.

The aviation meet here has been disappointing. Yesterday only the speed contest was begun, and none of the contestants covered the minimum distance of eight kilometers. Leblanc, on a Blériot monoplane, turned a somersault on alighting, but was not injured. To-day Henry Farman made eight rounds of the field, covering twenty kilometers in eleven minutes. Blériot made five rounds. Orville Wright is not participating, and his failure to appear has done much to spread the feeling that the meet was incomplete. The public turned out in large numbers to see the "bird-men" and was consequently greatly disappointed.

WRIGHT THREATENS FOREIGN AEROPLANES

Two aeroplanes arrived in New York last Sunday on the *Chicago,* and caused no little worry to the customs officials. One was the machine Curtiss used at Rheims, and the other the Farman biplane brought over by J. W. Curzon, of Jackson, Miss. Wilbur Wright has threatened to enter a suit against Mr. Curzon on the claim that the Farman machine infringes his patents. Mr. Wright also threatens a suit against Hayden Sands, of New York, who has purchased a Blériot machine, which is expected to arrive in a few weeks.

The owner of the latter, as well as the French builder have given expression to opinions to the effect that the Wright patents are worthless, and say that they will fight the case out to the limit. It promises to be a very hard fought case.



Krupp Gun Designed to Annihilate War Airships

GERMAN AUTOMOBILE AIRSHIP GUN

Frankfort, Germany, Sept. 27—The Krupp Company is exhibiting at the Frankfort Aeronautical Exposition an ingenious automobile gun for fighting airships. The chassis has a 50-horsepower motor which drives all four wheels, in order to maneuver more easily on rough ground and steep grades. The platform affords room for five men and sixty cartridges. The gun is mounted on a steel pedestal, and can be trained through an arc of 360 degrees horizontally and 180 degrees vertically. When it is to be fired the platform is secured by struts to take the shock off the frame and axles. The projectiles weigh 11 pounds each, and leave a trail of smoke in the air to assist the gunner in finding the range. The gun and car complete weighs 4315 kg. (9500 pounds). The maximum range horizontally is 9100 meters (5.64 miles), and vertically 6300 meters (3.9 miles).

CLEVELAND INVENTOR HAS BALLOON GUN

Cleveland, Sept. 27—Dr. S. W. McLean, of this city, has built an airship gun which has received some preliminary tests mounted on a Baker electric truck. The gun itself appears to be the usual naval type of semi-automatic, firing a six-pound shell. It is capable of delivering 200 shots per minute. The mounting has been altered to allow of a maximum elevation of about 45 degrees According to Dr. McLean, the difficulty is to devise a missile which will damage the airship, even if it does hit it. The ordinary shell will not explode under less resistance than that offered by a one-inch pine board. The idea of the new gun is to riddle the dirigible or aeroplane by a number of shells, not depending on their explosion. For this purpose mobility is the prime requisite.

American Weapon Built to Destroy Aerial Fighters

NOW KILL AERIAL GORDON-BENNETT

PARIS, Sept. 24—The cry, "Kill the Gordon-Bennett," has again gone forth. This means the trophy just won by Curtiss at Rheims. The French review, *L'Automobile,* has uttered the cry of death in the following note:

"It appears to us that French aviators have nothing to gain by taking part in this event, and that it is calculated, indeed, to do much evil to the French aeronautical industry. The reason is simple. There are at present not less than ten aeroplane constructors in France. What do we see abroad? Two Americans took part in the competition at Rheims and no other competitors existed anywhere. What is more extraordinary would have been to see Farman fly for England, for he is of English nationality, while at the same time being essentially Parisian. In any case he is a member of the French school, and in that respect as much French as Bleriot or Levasseur. Suppose Farman had won the Gordon-Bennett cup; every foreigner would have declared that the English aeronautical industry was at the head of the world and that the French product was inferior.

"America is the only country that can meet us in aeronautical matters. The Wrights have presented series of machines which class them among the best constructors. As to Curtiss, the winner of the cup, he has only one machine of this type. In France there are various constructors, among them Bleriot, Antoinette, Farman and Voisin, who are daily selling machines to the public. Elsewhere only the Wrights are in this position.

"Under these conditions we are playing the rôle of dupes in taking part in a competition in which equal importance is given to the industry of various nations. We are about to repeat in the aviation world what was done in the automobile world, where France played into the hands of the German, English and Italian industry, by putting on the same footing the fifty French factories and the rare foreign factories.

"The cup has been gained by a compatriot of the generous donator. It has gone to America. Let it stay there forever. It is to be hoped that our constructors will see the danger at once, and that they will inform the Aero Club that they have no further desire to take part in such an event."

Had Blériot, who placed such importance on the winning of the cup, been successful in his attempt, it is certain that such a wail would never have gone forth. This causes the whole affair to look very unsportsmanlike, because the French are losing.

THEORIES AS TO LEFEBVRE'S DEATH

PARIS, Sept. 24—Juvisy, the Paris suburban aerodrome, should provide a series of good races from October 3 to 17, if numbers of participants count for anything. The entry list has been closed with 34 names, many of which, it is true, are those of newcomers never having been aloft, but at the same time including a number of veterans. Among the important pilots are Hubert Latham, Leon Delagrange, Henry Fournier, Comte de Lambert, Jean Gobron, Louis Paulhan and Henri Rougier.

After an examination of the wreckage of the Wright biplane and a close inquiry into all the conditions, two theories are put forth regarding the unfortunate death of Eugene Lefèbvre, the Wright pilot. One is that the front elevation rudder controls either broke or jammed while the planes were in position for descending. The motor running and continuing to run, the fall of the apparatus took place at a terrific speed.

The other theory, put forth by the constructors, is that after the smash the controls were found to be bent, but were not broken. Thus the machine must have been overturned by a gust. At the moment the rudders were set for a downward sweep a gust of wind caught the machine from above. The apparatus quickly passed its central pivoting point, and nothing that the pilot could do could bring it back to an even keel within the thirty feet drop at his disposal. Had he been at a height of 100 feet it would have been possible to get on an even keel before striking the ground.

FRENCH DIRIGIBLE BURST IN FLIGHT

NEVERS, FRANCE, Sept. 25—The military dirigible *République* burst while in flight near here to-day. Four army officers, who formed its crew, were instantly killed. It is believed that the accident was due to the breaking of a propeller, the pieces of which ripped through the envelope. The torn remnants failed to form a parachute, as they often do in such cases, and the wreckage fell straight to the ground, a distance of 300 feet.

French Aviator Victim of Accident

BOULOGNE, FRANCE, Sept. 22—Captain Louis Ferber was killed at the end of a successful flight near here to-day. His machine was a Voisin biplane. In landing, one of the wings struck the ground and caused the machine to turn a somersault.

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

Nov. 6-13	Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers, Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.
Dec. 31-Jan. 7	New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
Jan. 8-15	New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
Feb. 5-12	Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.
Feb. 22-26	Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.
March 5-12	Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.
Nov. 12-20	London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

Races, Hill Climbs, Etc.

Oct. 5-9	Danbury, Conn., Stock Car Races in Connection with Danbury Fair.
Oct. 8-9	Louisville, Ky., Endurance Run, Louisville Automobile Club.
Oct. 7	Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City M. C.
Oct. 15	New York City, Brighton Beach Track, 24-Hour Race (postponed from September 24), Motor Racing Association.
Oct. 16	Denver, Col., Start of "Flag to Flag" Reliability Run, G. A. Wahlgreen, Manager.
Oct. 23	San Francisco, Road Race, Automobile Club of California.
Oct. 28-30	Dallas, Texas, Three-Day Track Meet, Dallas Automobile Club.
Oct. 30	Vanderbilt Cup Race, Long Island Motor Parkway, Motor Cup Holding Company.
Nov. 8-9	Savannah, Ga., Georgia Highway Reliability Contest to Atlanta, Savannah Automobile Club.
Nov. 9	Atlanta, Ga., Track Races, Atlanta Automobile Association.
Nov. 20-21	New Orleans, Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary-Manager.
Dec. 29-30	Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.
Feb. 4-6	New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

What the Clubs Are Doing These Days

NEW CONNECTICUT LAW IS UNPOPULAR

New Haven, Conn., Sept. 27—The directors' meeting of the Connecticut Automobile Association last week made it apparent that the new automobile law does not meet with universal approval. C. M. Robinson, chairman of the legislative committee, made a report on the work with the last legislature. He said that it was the practice of the committee on roads of the legislature to agree to suggested measures and later to ignore the agreements and bring in a different report. "We could have obtained just as much by letting them go ahead and draw up any old bill they saw fit, instead of trying to be reasonable and meet them half way. The whole thing was run by politics." He strongly advocated that the association contest the new law, on the ground of unconstitutionality. In this he was supported by Joseph P. Tuttle, the association's attorney.

In the general discussion which followed it was agreed that although the taxation was unjust, automobilists should be willing to contribute a reasonable amount since the money is to be devoted to road improvement. The general opinion seemed to be that 40 cents per horsepower was all right, but that making the rate 50 or 60 cents was "rubbing it in." In the absence of President Fuller, Vice-President Staples, of Bridgeport, presided.

HARTFORD CLUB IN NEW QUARTERS

Hartford, Conn., Sept. 27—The Automobile Club of Hartford is now located in its new home in the Allyn House Annex, 201 Trumbull street. At the recent house warming and formal opening nearly the entire membership attended, and Mayor Hooker, who is a prominent member, was present to carry out his part of the program. The rooms have been newly fitted up with mission furniture and with every facility to make it pleasant for members to drop in frequently. The hotel café connects with the club quarters, and the members can thus have the house service at any time. The list now has about 300 names of active participants.

Road maps, touring information, and a clerk to attend to the wishes of touring autoists in this particular, are important parts of the new programme of the club. Accurate touring directions may thus be obtained, and special care will be taken to keep posted on all road repair work, so that detours may be made, if necessary, en route.

JERSEYITES TO HAVE CLUBHOUSE

Newark, N. J., Sept. 25—The proposition of securing a club house came up for general discussion at the third dinner of the New Jersey Automobile and Motor Club last Wednesday evening, at the present quarters on Park place. The banquet was one of the most elaborate of the season, and more than fifty members were present. The club requires more room for social functions than is afforded at the present location, and it seemed that its interests would be best served by the change. The matter was finally decided favorably, and a new location will be secured.

SEA ISLE, N. J., HAS AN AUTOMOBILE CLUB

Sea Isle City, N. J., Sept. 27—The Sea Isle City Motor Club has been permanently organized by the automobilists of this city. Over thirty members have already been enrolled, with prospects of securing eighty by the end of the season. The following officers have been elected: Charles Woertz, president; Bismarck Kiessewetter, vice-president; Walter Brooks, secretary and treasurer. A committee on constitution and bylaws was appointed, consisting of Messrs. Coyle, Beckett and Bell, and it was decided to apply to the A. A. A. for a charter.

PHILADELPHIA ROADS AND SIGNS IMPROVE

Philadelphia, Sept. 27—The Philadelphia Automobile Club deserves the good-will of every automobilist who has used the roads in the vicinity of the Quaker City this summer. Apart from its signboarding work—which benefits everybody who travels the roads—and its maps and routes, the club has been getting down to the actual work of putting the roads in shape, or at least of providing the means therefor. There was one bad stretch in particular on the New York-Philadelphia route which no one seemed in any hurry to improve. The club bought a King split-log drag and so interested the turnpike company that it put a top dressing of stone on the bad stretch and ironed it out with a steam roller. The method of the chairman of the club's good roads committee is to take the road supervisors out in his car and show them just where the roads ought to be improved, and it is working to perfection. The authorities get busy immediately after this ocular demonstration, and the result has been the elimination of any number of bad spots on the turnpikes leading into the city.

BALTIMOREANS TO CONFER WITH LAWMAKERS

Baltimore, Sept. 27—Members of the Automobile Club of Maryland are anxious to have an amicable agreement with the Automobile Commission in regard to the proposed bill which the commission will present to the General Assembly next January. It has been decided to invite Governor Crothers, Mayor Mahool of Baltimore, the Baltimore County Commissioners and the members of the Automobile Commission to attend a special meeting of the club within the next few weeks. The club members wish to have some agreement reached regarding the special tax and a more liberal speed limit than the present 12-mile one.

Osborne I. Yellott was appointed to head a committee to cooperate with the Baltimore County Commissioners for the placing of road signs about the state. It was also decided to have the club publish a road map for tourists.

NATIONAL SIGNPOSTING DAY SUGGESTED

Columbus, O., Sept. 27—Members of the Columbus Automobile Club are enthusing over the prospects for the establishment of a national signposting day. The club has been very active in this particular during the present season, and appreciates the value of a plan along more extended and uniform lines. Many of the members have offered to assist in erecting guides on all the roads of the central part of the State. A nuisance which will be fought is that of vandals who destroy the automobile club posters, and it is probable that an effort will be made to have the Legislature constitute this a misdemeanor, with suitable punishment. This is a despicable trick and the club is being commended on every side for the firm stand which it has taken, even by people who do not drive an automobile.

COLUMBUS, O., PLANS "OLD PEOPLE'S DAY"

Columbus, O., Sept. 27—"I am over 70 years old and I have never ridden in an automobile," said an aged man in front of a Columhus business house recently. W. E. Heskett, a member of the Columbus Automobile Club, heard the statement and immediately got busy. After conferring with the officers of the club a movement was started for an "old peoples' day," similar to orphans' day. It is proposed to give all old people over threescore and ten a long automobile ride and entertain them at the clubhouse some time in October. The movement is finding support on all sides and already many members of the club have volunteered the use of their cars.

THE AUTOMOBILE

GERMANY:—A. Seydel, Mohrenstrasse 9, Berlin.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

WHAT SHALL THE MATERIALS BE?

Following the establishment and fitting out of many and very complete laboratories comes the natural sequence, the results obtained therein. These take divers forms, some following along and amplifying present and past knowledge, others simply bearing out what has been said in previous years before complete testing equipments were available, and on the whole adding nothing to our knowledge. Then there is a third class of results, which have had a startling effect. These are the tests which have upset previous theories in many cases.

In cases of this sort there remains much work for the laboratory to do in the way of repeating the proof, and verifying it, until the newer idea has been placed upon a firm footing. In the line of materials there has been much room for this sort of thing, and the forehanded manufacturer has gained not a little by the work of his chemists and testers.

As noteworthy of the whole range of special metals, for which it may be said that the automobile has developed them, is the ultra-lightweight metal, aluminum. When first brought out, this was hailed as the successor of cast iron, and in some cases of steel and malleable iron, for motor car use. Time proved that the strength was lacking for the two latter uses, although it persisted as a substitute for the first named. Now, it would appear as if the growing feeling that it was too treacherous a metal to use has been proved by modern laboratory tests. Coupled with the tendency to lower prices for cars, and the still later medium-priced car, it appears as if the metal for automobile use is on the downward path.

Any mention of the price of the latter-day cars, in particular the very low-priced runabouts, shows that the metal is, there at least, out of place. To put it otherwise, what place has 60-cent-a-pound metal, and unreliable at that, in a car listing at $950?

STATUS OF SPEED CONTESTS

The year has been remarkable for the number of racing events which have taken place in this country. No less than four road races of national importance have been run or are scheduled, besides many local ones. One large automobile track has been opened, and another will open within six weeks. In addition, there have been about the usual number of races on mile tracks, in spite of the agitation against this form of the sport.

Several conclusions may be drawn from this unexpected abundance of speed contests. First, that automobile racing has a firm hold on the great mass of the people, the class whose support is necessary to the success of such costly enterprises as have recently been undertaken. Second, that the races are now on a commercial basis. The good of the industry has ceased to be the consideration. Much as we may regret the passing of the picturesque old days, it cannot be helped. Perhaps the reason is that the industry is too big to be coddled.

PROGRESS CLAIMS ITS VICTIMS

The progress of the sciences of aviation and aerostation has claimed, during the past month, the sacrifice of six human lives. To the names of Lilienthal and Selfridge must now be added those of Etienne Lefèbvre, Captain Ferber, Captain Marchal, Lieutenant Phaure and Sub-Lieutenants Vincenot and Reux. Such wonderful advances have been made this summer in the practice of these sciences that the worst danger seemed past. We now realize how scant is our knowledge, in comparison with that which is yet to be learned.

The lessons which misfortune can teach should not, however, be neglected. These accidents have discredited two theories which formerly were widely believed. It had been contended that, if the envelope of a dirigible should be punctured, allowing the gas to escape, that the envelope would still act as a parachute to retard the descent. This has happened several times in the case of spherical balloons, but the disaster to the *République* shows that dirigibles do not act in the same manner. On the other hand, there have always been dire prophecies of the danger of an aeroplane's motor stopping in mid-air. Several such incidents have now demonstrated that no consequences need be feared in such cases except the curtailment of the flight. The accidents to both M. Lefèbvre and Captain Ferber took place with the motor running and the machine flying low. On the whole, we think that the advantage has been with the aeroplanes. Just what the future will bring forth to prove or disprove the worth of either form remains to be seen. From the viewpoint of the present day status of the two, the balance seems to favor the birdlike form.

ACCESSORY ALLOTMENTS FOR ATLANTA SHOW

ATLANTA, GA., Sept. 27—Forty members of the Motor and Accessory Manufacturers' Association have taken space at the Atlanta automobile show, which is to open November 6, and practically all the leading parts and accessories makers in the country are included in the list. The allotment of space among the members of the association was completed Monday by the show committee of the M. and A. M. and contracts are now being mailed. More than 7,000 square feet of space has been disposed of in this distribution.

One of the features of the show, according to the latest reports, is to be a collection of oil paintings illustrating automobile scenes. These paintings, the work of well known artists, will be 8 by 24 feet in size, and a score of them will be used as decorations around the elevated platforms. The use of such paintings shows the pains taken to make the show a success.

The following is a list of the members of the M. and A. M. A., who will be represented at the show:

Ajax-Grieb Rubber Co.
Badger Brass Mfg. Co.
S. F. Bowser & Co.
Byrne, Kingston & Co.
Conn. Telephone & Electric Co.
Diamond Rubber Co.
Jos. Dixon Crucible Co.
Dow Tire Co.
Electric Storage Battery Co.
Empire Tire Co.
Federal Rubber Co.
Firestone Tire & Rubber Co.
Fisk Rubber Co.
G & J Tire Co.
B. F. Goodrich Co.
Gabriel Horn Mfg. Co.
Goodyear Tire & Rubber Co.
A. W. Harris Oil Co.
Hartford Rubber Works Co.
Herz & Co.
Kokomo Electric Co.
Jones Speedometer Co.
Leather Tire Goods Co.
C. A. Metzger Co.
Michelin Tire Co.
Morgan & Wright.
National Carbon Co.
Never-Miss Spark Plug Co.
N. Y. & N. J. Lubricant Co.
Oliver Mfg. Co.
Randall-Faichney Co.
Republic Rubber Co.
C. A. Shaler Co.
Stromberg Motor Devices Co.
High Wheel Auto Parts Co.
C. F. Splitdorf.
Sprague Umbrella Co.
Veeder Mfg. Co.
Weed Chain Tire Grip Co.
Hartford Suspension Co.

TIRE PRICES ARE AGAIN INCREASED

AKRON, O., Sept. 27—The increased price of crude rubber is alarming tire manufacturers. The Goodyear Tire & Rubber Company has announced an increase of 15 per cent. in the price of its finished tires, and similar announcements are expected from the Goodrich, Diamond and other companies, in addition to the increases made several months ago. The best grade of crude rubber was quoted last week at $2.10 per pound, and rubber men say that tires now cost to make 25 to 30 per cent. more than a year ago. The only hope the manufacturers see of checking the steady rise is that the cultivation of rubber will be made practicable, and all attempts to do this so far have been in vain.

Sixty branch managers and tire salesmen of the B. F. Goodrich Company were here for two days last week, and were in conference with the officers of the company. Among those present was A. E. Lumsden, the European manager, who makes his headquarters at London.

"AROUND LONG ISLAND" POSTPONED

The New York Automobile Trade Association has thought it advisable to postpone the "Around Long Island" tour, originally scheduled for September 28 to 30, to a later date, because of conflict with the Hudson-Fulton celebration. The members of the association, while ostensibly enthusiastic over the prospects of the tour, had developed an embarrassing unwillingness to absent themselves from the metropolis on those three days. In addition, the sanction from the contest board of the A. A. A. was not forthcoming, as expected, because several features of the A. A. A. rules had not been embodied in the Trade Association regulations. The delay will give time for the adjustment of this matter, and will also allow the members of the association to take part in the general festivities.

While the postponement has caused much disappointment, it is in line with many other similar changes of dates caused by the celebration.

DO WOMEN MAKE SAFE AUTO DRIVERS?

MILWAUKEE, WIS., Sept. 27—There has been some agitation in this city toward prohibiting the operation of automobiles by women in the downtown district, but the council probably will not take any notice of the matter. A majority of automobilists oppose such action, reasoning that women make better drivers than men; that they do not take chances, are the least reckless, and maintain the speed limits more conscientiously than men. No cases are on record in Milwaukee of accidents to cars operated by women. In view of these facts, it is likely that the agitation will be short-lived.

EXPORT TRADE DISCUSSED BY COUZENS

"No American maker should look for foreign trade with the idea that it is to be obtained easily," said James Couzens, of the Ford Motor Company, when he landed from the *Caronia* after a six weeks' trip through England, France, Germany and Switzerland. "There is an opportunity abroad to sell a great many American cars, and the field is constantly enlarging. In order to obtain the business, however, European conditions must be carefully studied." According to Mr. Couzens, 115 Ford cars were sold in France this year, and the French agent, Henry De Passe, has ordered 300 for 1910. A branch has been established in London at 55 Shrewsbury avenue. The French are expecting great things of the new car manufactured by the Darracq Company, a 20-horsepower four-cylinder machine to sell at $1,000.

VANDERBILT CUP ENTRY BLANKS OUT

With the receipt of word from Buffalo recently, to the effect that Chairman F. B. Hower had granted a sanction for the Vanderbilt cup race, on Long Island, Oct. 30, the last obstacle has been removed. The Motor Cups Holding Company immediately opened offices in the Long Acre Building, at Seventh avenue and Forty-third street, from where entry blanks have been issued.

Boxes and seats in the grandstand have also been placed on sale at the offices, and so great has been the interest displayed to date, that the offices will be kept open nights. Enough entries have been already made or promised to insure a good, fast race.

N. A. A. M. STARTS TRAFFIC DEPARTMENT

Information on any matter pertaining to the shipment of automobiles can be obtained from the traffic department of the National Association of Automobile Manufacturers, 7 East 42d street, New York. In order to give dealers the fullest benefit of its work, the executive committee of the association has notified them to this effect. The service of the traffic department will include advice as to correct freight rates, and the collection, without charge, of claims against railroads for overcharge, or for loss or damage.

OHIO LICENSING SEEMS PROFITABLE

COLUMBUS, O., Sept. 27—The report of State Registrar of Automobiles Caley for the month ending September 15, indicates an increase in the number of automobiles registered and also the usual number of renewals. Owners have registered new cars to the number of 603, bringing in a revenue of $5,277. Manufacturers and dealers to the number of 20 paid license fees of $1 each, and 225 chauffeurs were registered. The total revenue of the department for the month was $8,192.

Arrival of Mitchell Transcontinental at San Francisco

Presenting Major-General Wood's Despatch to Major-General Weston at Pacific Coast U. S. Army Headquarters, Presidio.

GOOD ROADS HELP SALE OF AUTOS

CLEVELAND, Sept. 13—"Millions for good roads" is the slogan of the middle West and the further West, according to O. B. Henderson, sales manager of the Baker Motor Vehicle Company, who has just completed a tour of that part of the country. For two months he was visiting the sections where the automobile business is rapidly increasing, and he says: "The good road ideas are spreading remarkably. One county in California, alone, has appropriated a million dollars; Seattle is cutting down its hills; cities are constructing boulevards; States are pushing out splendid highways, and improvement is evident everywhere. It is a prophecy which the wise dealers are heeding, and modern, substantial buildings are going up in many places. Foresighted business men are securing the agencies for well-established automobiles, and all of this is caused by the growing demand for better roads.

"I find the sale of electric vehicles increasing immensely, for years of steady growth have been followed by a sudden desire for this type of automobile. I found electrics in many places where a year ago there were none. City men are realizing the field which these cars have that in no way conflicts with the one of the gasoline cars, especially for family use or when women wish to operate their own machines. The most remarkable development is the introduction of the gasoline automobile in the farm life of the middle section. Farmers do their traveling in this way and this will be a bonanza year for automobiles.

MINNEAPOLIS AUTO MAKERS ENLARGE

MINNEAPOLIS, MINN., Sept. 25—The continual growth of the automobile industry in the Northwest is becoming noticeable in many directions. The retail trade has increased by leaps and bounds and now comes the anouncement of interesting doings by the manufacturers of this district. This city will become an important factor in the automobile and truck manufacturing lines, for the local concerns engaged in this work have recently been reorganized to handle a much increased amount of business. Between 3,200 and 3,500 machines will be turned out during the coming season.

The Wilcox Motor Car Company has been put upon a million-dollar basis and is arranging to construct 3,000 touring cars and about 100 trucks. P. W. Strong, for many years the sales manager of the Welch Company at Pontiac, Mich., has been secured to handle the pleasure car end of the business, and John H. Shields, the present sales manager, will take care of the commercial department. The president of the new concern is Harry E. Wilcox, the man who has been most influential during the past three years in bringing success to the company. C. H. Davidson, of Carrington, N. D., and John F. Wilcox, of this city, are principal financial backers of the Wilcox Company. It is the impression that a car which will sell for about $1,500 will be produced, following in a general way the design of the former Wilcox cars. It will have 16 inches road clearance and double side-chains.

The Minneapolis Motor & Truck Company has recently been organized to market its own product consisting of trucks and pleasure cars designed especially for the use of the farmers. The firm is capitalized at $100,000, and is engaged now in building a factory. Its first models have appeared and have met with favor.

Jersey City, N. J.—One of the finest garages in New Jersey will be the new home of the Crescent Automobile Company in September. The new building is on the site of the old one, at the Boulevard and Duncan avenue, and will be three stories high, 70 feet wide and 100 feet long. The first floor will be used for offices, show rooms and garage; the second will be used for storage purposes; and the top, for a repair shop. The agency for the Cadillac, Peerless and Pope-Hartford is held.

Baltimore—A handsome garage at 1113-15 East Mount Royal avenue has just been completed, and is occupied by the Zell Motorcar Company, formerly on Morton street. The building is of steel, concrete and brick, 50x100 feet, three stories high. It is attractive in appearance, with a front of tapestry brick.

How Two Enthusiastic Maxwell Owners Solved the Vacation Problem in a Unique and Enjoyable Manner.

With a family of moderate means the vacation problem is always a perplexing one. The illustration shows how R. L. Shipman and F. C. Edminister managed to have the best time ever, touring Central New York with their families, the party including three adults, six children, and the dog "Flip."

1. Admiral Robley D. Evans Rounding Cape of Good Hope, Grossmount So. California

2. Adm. Evans, Col. Fletcher, and "King Edward" Gross, whose likeness to the British Soverign gets him into trouble every time he visits London.

AUTOING ROUND "THE CAPE" WITH AN ADMIRAL

By JAMES A. CRUIKSHANK

FIFTY years at sea have only served to make Rear Admiral Robley D. Evans, the beloved "Fighting Bob" of the American navy, the keener lover of the beauties of the land and the joys of speedy travel over perfect roads. For a man who has seen and participated in all the great naval progress of the past half century, the Admiral is one of the most progressive enthusiasts over the newer method of land cruising that could be found. Last Winter, after the cruise of the Atlantic Squadron from Hampton Roads to San Francisco, the Admiral, relieved of his command by the stern decree of his doctors, began an overland cruise from the Pacific coast to the Atlantic. This was partly in response to requests for lectures and addresses and partly for the purpose of seeing many sections of the United States which he had never before visited.

He did not take his departure for the East, however, until he had spent many weeks in Southern California. That region is indeed an automobiling paradise, and no single spot there is better adapted to the pleasures of the sport than the charming little city of San Diego. Some of the trips to be found in that vicinity are unsurpassed by anything of their kind on the continent; for instance, the journey to the Old Mission, or the day's run about exquisite Point Loma, where the Theosophists have their headquarters. Such distinguished people as A. G. Spalding, the baseball magnate; John D. Spreckels, the sugar king, and Lyman J. Gage, ex-Secretary of the Treasury, have settled here, and world-famous stretches of road are being built of disintegrated granite.

But without doubt the most interesting trip in this region is to the summit of Grossmount, some twenty-five miles to the west of San Diego. Such, at least, was the opinion of Admiral Evans. Grossmount is primarily the result of the daring engineering skill of Col. Ed Fletcher of San Diego, a Westerner with faith in himself and his wonderful country, who saw the place, scaled its heights in hobnailed boots and came back with a road drawn on his cuff. It was not long before that road began to eat its way into the solid rock of that titanic upheaval, amid which the luxuriant vegetation which only California knows grows as in a garden. In association with Col. Fletcher came another Californian, "King Edward" Gross, whose striking resemblance to the sovereign of England gets him into trouble every time he goes to London. These two men finally drove that wonderful piece of road-building clear to the inspiring heights of the summit, providing their city and its visitors with one of the most superb views on the continent. Mile after mile of checkered farm land lies at the feet of the spectator, and to the far east and north rise the snow-capped peaks which are the perpetual delight of the dweller in the sunshine below.

This road is so tortuous, so daring in its swings around the edges of precipitous cliffs and jagged ravines, that it has the superlatives crowding the expressions of the traveler every half mile. It is as smooth as a billiard table, being made of that disintegrated granite, which, next to the shells of the sea, makes the finest road mankind has so far discovered. The apotheosis of this superb climb is found in the "rounding of Cape Horn," a jagged bunch of geological odds and ends grouped close to the summit of the peak. Here the wind gods hold high carnival, and the road is so narrow that but one machine can use it at the time. But a true Westerner never knows when to slow down. When Admiral Evans made this trip, Col. Fletcher, who was chauffeur, swung his Franklin round those dizzy heights in such fashion that he could not restrain exclamations of surprise. Finally the grizzled veteran of the sea paid the skillful driver one of his characteristically quaint compliments.

"Young man," said he, "I appoint you herewith chief steersman of the swiftest torpedo craft in the United States Navy. You surely know your job."

Breaking Ground for Addition to Overland Plant at Toledo, O.

Quick Work in Building Factory—Ground has just been broken for the five-story, 100 by 600 foot addition to the Overland plant at Toledo, O., to be used by the finishing department. The photograph was taken two days after the contract was let, and gives only a small idea of what was actually going on, as it was said that at the time there were 500 men and 100 two-horse teams at work. On taking possession of the Toledo plant the Overland Company found itself handicapped in various directions. The shipping facilities were entirely inadequate, especially in view of the prospective output of 80 cars a day. New spur tracks and sidings had to be run in and platforms and shipping rooms built. The brick building shown in the background of the photograph was especially built for the construction of radiators, frames, oilers and other parts. Many thousand dollars' worth of old machinery was scrapped, to be replaced by later and more modern equipment. When it was found that more room was needed for the finishing department plans for a new building were drawn and a contract was let calling for delivery, ready for occupancy, within 40 days.

Rushmore to Build Again—The Rushmore Dynamo Works, of Plainfield, N. J., has extended its capacity by the erection of a large fireproof storehouse, and will soon break ground for a two-story 50 by 200 concrete addition to the machine shop. In addition to over 300 horsepower already supplied by the power plant, a 125-horsepower gas engine is to be installed soon. One entirely new department has been added, for the silvering of lenses; this enables the factory to make its lenses complete from the rough discs to the finished product. As these lenses are not made from the ordinary "green" glass, but from annealed optical lead glass, the economy resulting from the saving of the optical manufacturer's product is an important item.

Trucks on Maintenance Contract—The Rainier Motor Truck Company, recently organized, is to act as agent for the Reliance commercial cars in New York City and proposes to offer purchasers a maintenance contract, whereby, for a stated sum per year, the trucks it sells will be kept in repair and their operation guaranteed for a term of years. John T. Rainier, P. N. Lineberger and G. C. Comstock are the incorporators of the new company. Messrs. Rainier and Lineberger were among the first to introduce electric trucks in New York City on a large scale. A garage will be opened at Fifty-first street and Twelfth avenue and trucks of 2½, 3½ and 5-ton capacity will be sold, with bodies to suit the purchaser.

Prepares for Moon Visitors—Several hundred Moon owners are expected to drive to St. Louis to witness the Centennial week celebration, October 4 to 9, and the Moon Motor Car Company has been making arrangements to welcome them to the city. The company will provide for their entertainment, and will award trophies to those making the longest runs. All the Moon cars available in the city, as well as the visitors, are expected to participate in the automobile parade on October 9. The Moon Company has announced that it will gladly furnish any information or aid possible to prospective visitors.

Mason Meets Its Waterloo?—The Mason Automobile Company, of Des Moines, Ia., has definitely arranged to move to Waterloo, Ia., and expects to be settled in the latter city by the end of October. The capital of the company has been increased to $500,000. The new plant at Waterloo comprises three buildings, 100 by 300, 120 by 160 and 70 by 120, and it is planned to make further additions to the available space. As an evidence of confidence in the Mason the citizens of Waterloo placed an order for 100 1910 cars.

The Better the Road the Better the Car—In the official program of the National Good Roads Convention at Cleveland there appeared this advertisement by the Knox Automobile Company:

"Put us down as being for good roads. The better the road the better the car, and conversely, the better the car the better the road. We are constantly working to better the car, but we are with you on the other end of the proposition."

Big Deal in Northwest—It is reported that C. F. Van Sicklen, sales manager for the Fal Motor Company, Chicago, has just closed a big agency contract with the Northland Motor Car Company, of Minneapolis, which calls for 950 cars. The company is composed of W. D. Rightmire and Harold Vorce, the only other car handled being Stoddard-Dayton. Although in receipt of over thirty orders from that city, the big contract requirement took Van Sicklen's breath away.

First Taxicab in Montreal—The first taxicab to make its appearance on the streets of Montreal attracted considerable attention. It is the first of a large number to be placed in operation by the Berna Motors and Taxicabs, Ltd. W. P. Kearney, the manager, said that regular service would not begin till next Spring, as it had been found necessary to have motors specially constructed to overcome the steep grades of the city.

Thomas to Use Truffault—The use of Truffault-Hartford shock absorbers on Thomas cars during the last season has proved so satisfactory that the Thomas Company has decided to specify them as stock equipment on its entire 1910 product. This announcement is of interest, in view of the growing tendency among manufacturers to sell their cars completely equipped for the road.

Canadian Bank Uses Auto—The Bank of Montreal is now using an automobile to convey its messengers with money and documents between the head office and the branches in the city. The messengers' headgear is not unlike the German army cap, and when three or four of the boys get into the car it looks as though the Kaiser's bodyguard had come to town.

Olds Increases Capitalization—The capital stock of the Olds Motor Works, according to amended articles of incorporation filed with the Secretary of State of Michigan, has been increased from $2,000,000 to $4,000,000. The reason for this increase has not been disclosed, but it is supposed that it is a part of the plan of reorganization of General Motors.

For the Suppression of Noise—The Xargil Mfg. Co., of Utica, N. Y., a manufacturer of mufflers for automobiles and motor boats, will move into a new plant on October 1. It will then be located in a large three-story building at 34-38 Broadway, Utica, which, it is said, will be the largest plant in the country devoted exclusively to mufflers.

Hupmobile Pleases the Owls—The Hupmobile carried off the principal honors at the race meet held at Chillicothe, O., September 23, under the auspices of the Order of Owls. The races were held on the 1-2-mile track at the county fair grounds, and in spite of unfavorable conditions the time was fairly fast.

First Aid for Marylanders—The W. W. Garage & Machine Company, of Cumberland, Md., is building a "trouble wagon," driven by a 40-horsepower motor, which will carry a full shop equipment, spare wheels, parts, etc., for the relief of machines broken down on the road.

I. H. C. Now at Tiretown—The International Harvester Company has announced that henceforth the old plant of the Buckeye Mower & Reaper Company at Akron, O., will be used for the manufacture of I. H. C. automobiles of the high-wheel type.

IN AND ABOUT THE AGENCIES

Reo and Premier, Cleveland—These cars will be represented by an agency to be known as the Cook Motor Sales Company, which will occupy two floors of the building nearly completed on Euclid avenue above Twenty-second street. It is expected that 1910 models will be on exhibition there by October 1.

Apperson, Boston — Sales Manager George H. Strout has announced that the Apperson will be represented in Boston by W. L. Russell, who will establish temporary quarters at 369 Atlantic avenue. Later an office will be opened on Massachusetts avenue.

Stearns, Minneapolis, Minn.—A. G. FitzGerald and J. F. McKanna have formed the FitzGerald Selling Company, to handle the Stearns line in Minnesota, the Dakotas, upper Michigan and northern Wisconsin, with headquarters in this city.

Oldsmobile and Oakland, Atlanta, Ga.—The Olds-Oakland agency in this city is now settled at its new quarters at 132 Peachtree street. The garage, however, will continue at the old location on Auburn avenue.

Stewart Speedometers, Chicago—The Stewart & Clark Mfg. Co. has leased the building at 1312 Michigan avenue, formerly occupied by the Cadillac agency, and will take possession December 1.

Oldsmobile, Brooklyn, N. Y.—The A. W. Blanchard Company, 342 Flatbush avenue, which already holds the agency for the Waverley and the Herreschoff, has decided to take on the Oldsmobile.

Stoddard-Dayton, Minneapolis, Minn.—The Northland Motor Car Company has been formed by W. D. Rightmire and Harold Vorce to handle the Stoddard-Dayton in the Northwest.

National, Houston, Tex. — Clarence Martindale will handle the National here at 406 Scanlan Building. His territory will include Galveston, Beaumont and San Antonio.

Stearns, Detroit—The Palmer Auto Company has been agent for the F. B. Stearns Company, of Cleveland, and will handle the Stearns exclusively in this city.

Haynes, Boston—H. C. and C. D. Castle, the Lozier agents, have secured the New England agency for the Haynes, formerly handled by C. S. Henshaw.

Midland, New York City—The Midland Company of New York, which sells the Midland in the metropolitan district, is now located at 1851 Broadway.

Continental Tires, Boston—E. H. Kidder, resident manager of the Continental Caoutchouc Company, has opened his new office at 895 Boylston street.

Empire, New York City—The Poertner Motor Car Company, agent for the National, has decided to add to its line the new Empire "20" runabout.

Moon, Minneapolis—The agency for the Flour City has been taken on by the Segerstrom Auto Company, now handling the Rider-Lewis Six.

Jackson, Hartford, Conn.—A. E. Kilby has taken the agency of the Jackson, which was formerly held in this city by A. E. Lazarro.

PREMIER AGENTS AT THE HOME BASE

INDIANAPOLIS, Sept. 27 — Thirty-two agents of the Premier Motor Mfg. Co., coming from every large city between the Atlantic and the Pacific, were entertained here last week. It was a school of instruction as well as a sociable gathering. The agents were taken through the factory, shown the 1910 models, and loaded up with selling points for the coming year. A banquet was also given them at the Denison Hotel, at which H. O. Smith, president of the Premier Company, was toastmaster. The speakers included President Smith, Mayor Charles A. Bookwalter, R. I. Eads, Webb Jay, Charles Davis, Henry Eitel, of the Indiana National Bank; R. W. Macy and J. B. Orman. Later a sightseeing trip was made to French Lick; five of the cars used had been completed in the factory the preceding day and were untested.

MORLEY JOINS FORD COMPANY

DETROIT, Sept. 27—Walter G. Morley has succeeded H. C. Limbach as purchasing agent of the Ford Motor Company of this city. Mr. Morley is a pioneer in the gas engine and automobile field, having been connected with the Olds Gasoline Engine Works in the early days of the industry. When the Olds Motor Works plant was opened in Detroit in 1898 he was the purchasing agent. He has since been connected with the Aerocar Company, and as manager of the Canadian interests of the Reo Motor Company, located at Windsor, Ont. When this branch was discontinued Mr. Morley embarked in business for himself as a parts manufacturer. This business he has only recently given up to take his new position with the Ford Company.

Walter G. Morley

FROM INDIANAPOLIS TRADE CIRCLES

INDIANAPOLIS, Sept. 27—During the last week a number of new companies have been organized in this city, and many old-established concerns have made arrangements to increase their business during the coming season. Probably the most important of the new local companies is the Coesir Tire & Rim Company, which has been organized with a capitalization of $100,000 for the purpose of manufacturing a clincher tire invented by John L. Coesir.

The Maxwell-Briscoe Motor Company has leased a site at Illinois and Vermont streets, on which it proposes to erect a three-story sales branch building, at a cost of $60,000. A reorganization of the Cadillac Automobile Company of Indiana has been effected, and the name changed to the Peck Motor Car Company. The company has leased a building at 322-324 North Delaware street, which it will occupy immediately. Roy Shaneberger, John A. George and Oliver Shaw have organized the Reliable Auto Exchange and will open a salesroom.

At Richmond, Ind., the organization of the Pilot Motor Car Company has been completed with $100,000 capital stock. It will manufacture a line of gasoline cars. The automobile business which has been conducted at Anderson by John D. Clark has been reorganized under the name of the Clark Motor Car Company, and the plant has been moved to Shelbyville, Ind.

POPE COMPANY DECLARES DIVIDEND

HARTFORD, CONN., Sept. 27—At the meeting of the directors of the Pope Mfg. Co., held in New York City, a dividend of 6 per cent. was declared for the fiscal year ending July 31, payable September 30. When the new company was organized and new stock issued, the preferred stock carried cumulative dividends dating from August 1, 1908. The new company only began business December 24, 1908, so that it has made up a year's dividends in seven months—a record which speaks well for the management of the directors and for the business being done by the company. A further dividend, the quarterly from August 1 to November 1, was also declared, amounting to 1½ per cent. and payable November 1.

Sixty-One of the Eighty Firestoneites That Attended Convention

The annual convention of Firestone Tire & Rubber Company representatives, held recently at the factories of the company, at Akron, O., was the largest gathering of the Firestone selling force that has been held. There was plenty of enthusiasm over next season's prospects and an enjoyable time was interspersed with the business sessions

Chicago Branch House Where Will Be Met Western Demand for Continentals

CONTINENTAL OPENS CHICAGO BRANCH

CHICAGO, Sept. 27—The Continental Caoutchouc Company, maker of Continental tires and demountable rims, has opened a branch at 1412 Michigan avenue, in this city, which is one of the most attractively arranged automobile tire stores on automobile row. This branch will supply owners, dealers and manufacturers throughout the Middle West and has been established to care for the growing demand for Continental products. C. A. Gilbert, the resident manager, is always glad to welcome the automobiling public, and visitors are assured of courteous treatment and prompt fulfillment of their requirements.

PERSONAL TRADE MENTION

Walter A. Woods has been appointed manager of the New York City sales department of the Rainier Motor Company, with headquarters at Broadway and Sixty-fourth street. For the past season Mr. Woods has been connected with the New York branch of the E. R. Thomas Motor Company. He is a veteran salesman, with an extensive acquaintance of local trade conditions, and will conduct an energetic campaign for the Rainier for the coming season.

John E. Kay has been appointed assistant manager of the Maxwell-Briscoe Southern Company, at Atlanta, Ga. He was formerly with the Maxwell-Briscoe Motor Company at the Tarrytown, N. Y., factory.

K. T. McKinstry, formerly connected with the sales department of the Columbus Buggy Company, Columbus, O., has accepted a similar position with E. D. Crane & Company, of Atlanta, Ga.

F. H. Banbury, of the Acheson Oildag Company, Niagara Falls, N. Y., sailed for Europe September 25 to attend to the patent interests of his company.

William T. White has resigned his position with the Roebling Company to act as manager of the Mercer Automobile Company, another Roebling enterprise.

RECENT TRADE PUBLICATIONS

Peerless Motor Car Company, Cleveland—A wonderfully beautiful booklet, one of the finest productions imaginable, has just been issued by the Peerless Motor Car Company to illustrate its enclosed cars for 1910. In harmony with the luxuriousness of the subject, and of the high class of trade which will thereby be reached, the book is really a work of art. The illustrations are fascinating in their coloring and clearness, and the typography is splendid. Printed on heavy, embossed paper, with a cover of brown printed in gold and a touch of red, with the colors on the inside pages, this is an edition of which any concern might be justifiably proud. Those pictures which are intended to show the comfort of the limousine and landaulet as compared with that of persons traveling in snow and rain, either on foot or in cabs, are so much better than ordinarily seen out of the most expensive art books and magazines that they are especially noticeable. In all of these the principal car is the Peerless and the representations are so accurate, even in the most minute detail of automobile construction, that they are particularly pleasing. The cars themselves are fittingly shown, exterior and interior, and from several angles, while the tables indicating the size of the doors, height of the interior, size of the seats, and other similar details, give the correct idea of the machines at once. The specifications for inclosed bodies on both the four and six-cylinder chassis are included.

Pierce-Arrow Motor Car Company, Buffalo, N. Y.—"The Seal on the Door" is the title of the latest book issued by the Pierce-Arrow Motor Car Company, and it is "a symbol with historic suggestion," according to the statement on the first page. Two Pierce-Arrow cars are being used in the Presidential service at the Executive Mansion in Washington, and the story, written for the Pierce makers by John Foord, is a clever and dainty bit of history interwoven with former and present methods of locomotion for the Chief Magistrate and his family. The booklet is handsomely printed in black and colors, bound in a cream-colored, heavy paper, and the creamy effect pervades the interior also. The illustrations are impressionistic and appeal to the artistic, with their splashing of colors distinctively Washingtonian. The tale is an interesting one, not at all being a suggestion of advertising, for it is one dealing with scenes from the life of the White House taken from a period of slightly over a hundred years, and the episodes perhaps are those which do not often come to light. As compared with the days of old, when the coaches were not perhaps the best even for the President, are the circumstances now, when the two Pierce-Arrows, one of 36 and the other of 48 horsepower, are used by the occupants of the big house at the end of Sixteenth street. Both of these cars have the great seal of the United States painted upon their doors—the first time it has ever adorned the Executive equipage.

Hartford Auto Parts Company, Hartford, Conn.—Hartford universal joints and drive-shaft assemblies are favorably known in the trade and are used on many high-priced cars, so that this catalog assumes in some measure the importance of a compendium of engineering practice. Unlike the policy of some makers, who make the construction of their products a jealously guarded secret, the Hartford Auto Parts Company shows mechanical drawings, apparently reproduced from the original blue-prints, of each type of joint and shaft it manufactures, fully dimensioned and with all necessary data. Such frankness cannot help making a favorable impression on the engineer, who is keenly interested, and with good reason, in just these points which are so often concealed. The Hartford joints are made in sizes to transmit from 20 to 60 horsepower of the double yoke and cross-piece type, for drive-shaft use, and also in special designs for couplings between the clutch and gear-box. The company specializes on complete drive-shaft assemblies, with two joints, one sliding, and a shaft of any desired length between centers. The front joint may be provided with a brake drum. Shaft sizes range from 1¼ to 1⅝ inches in diameter. The catalog consists of eighteen loose sheets, each illustrating a single size or type.

Kellogg Mfg. Co., Rochester, N. Y.—Tire pumps of every possible variety are shown in the eight-page catalog issued by this concern. First on the list is the familiar compound hand pump, which is claimed to handle nearly twice the volume of air of an ordinary type. Another old stand-by is the quick-detachable engine-driven pump. An innovation in the pump line, however, is the new four-cylinder model, which seems to embody every latest improvement. It is furnished with a jaw clutch on the drive shaft, and either a gear or sprocket for the engine connection. All working parts run in oil. For use in garages there is a two-cylinder pump driven by an electric motor through a worm and gear. The motor is of 1-6 horsepower, either direct or alternating current, and may be connected to a lamp socket, for which purpose it is provided with 12 feet of cable. Twelve feet of tubing is also supplied, with a safety valve to prevent excessive pressure. As the outfit weighs but 40 pounds, it may easily be carried around the garage.

Lawrence Portland Cement Company, New York—In view of the extensive use of cement and concrete in garage construction, automobile owners should be interested in the booklet of the maker of "Dragon" Portland cement, which is favorably known in building circles. This booklet, issued from the sales offices at 1 Broadway, New York, really is a technical treatise on the uses of cement in every form. It gives specifications for standard mixtures of concrete, methods of testing, and information as to its proper employment. Readers of "The Automobile" will be interested in details of the construction of the Thirty-ninth Street Building, in which the editorial offices and press rooms of the magazine are located. This building is a fine example of the possibilities of concrete construction, as it is eleven stories high and contains many heavy printing presses.

Winton Motor Carriage Company, Cleveland—The Winton Six Upkeep Book, the second annual edition, has been issued to show the records of the Winton cars winning prizes for low cost of maintenance. The booklet is very artistically compiled and the statements of the judges and of those who won are very interesting. That a car can be driven for 17,003 miles without a cent being paid for repairs is wonderful. Other sets of figures are of equal importance. In each case of the ten, the details of the records kept for eight months are given, sworn to by both the chauffeurs and owners. It is especially noteworthy that the first three prize winners this year were not new machines, and these facts are well brought out in the edition.

American Tap & Die Company—Catalogue No. 3 of the American Tap & Die Company, of Greenfield, Mass., has recently been issued and is of special interest to the automobile manufacturers and trade. It illustrates threading tools, such as taps, dies, tap wrenches, die stocks, screw plates, etc., and gives a list of the various sizes in which these are made. There are now screw plates produced in the A. L. A. M. sizes, a move which will be welcomed by the autoists. The catalogue itself is a handy one to have where such tools are required, for by a systematic arrangement of head and foot notes there is no time wasted or trouble in looking for any certain part, and for its exact description.

Cox Brass Mfg. Co., Albany, N. Y.—This company makes a specialty of automobile brass work, and has issued a small catalog devoted exclusively to this line. There are included six different types of tire holders, at varying prices; almost as many designs of robe rails and foot-rests, and lamp brackets to suit everybody. This company also makes a compound tire pump of the lever type for garage use, and a lighter plunger pump. For use with liquid carbonic gas tanks there is furnished a new pressure reducer and regulator.

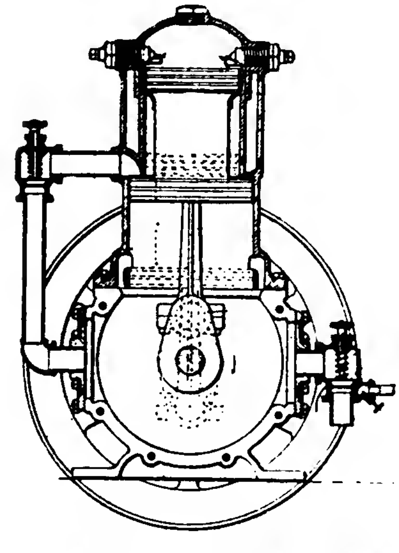
Firestone Tire & Rubber Company, Akron, O.—An artistic book on the subject of 1910 demountable rims for quick detachable and clincher tires is being distributed by the Firestone Tire & Rubber Company, Akron, O. The book illustrates the operation of tire-changing with these rims and explains why the Firestone company has discarded its demountable rims requiring clincher tires exclusively, in favor of the new Firestone demountable rims, which permit of repeated tire changes on the road.

SOME SELECTED AUTO PATENTS

Issue of Sept. 7, 1909

933,109. Gas Engine—Frederick W. Reeves, Pittsburg, Pa. Filed Feb. 22, 1908.

This two-cycle engine seems a rather com-

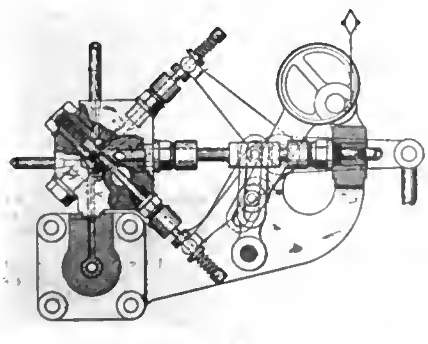


Concentric Piston Engine by Reeves

plicated embodiment of the differential piston idea. It consists of a compression chamber, to be swept through by the larger end of the piston, and a combustion chamber above the piston. The middle part of the piston is smaller in diameter than either end, and the space between it and the cylinder wall is called the secondary compression chamber. The fresh gas is first drawn into the crank-case, thence transferred through a by-pass into the compression chamber. As the piston rises the gas is compressed, at the same time that the exhaust gas is being driven out of the combustion chamber. When the piston is nearly at the top of its stroke it uncovers a series of by-pass ports, through which the fresh gas is transferred around the piston into tbe combustion chamber.

933,325. Fuel Feeder for Internal Combustion Engines—Norman McCarty, Indianapolis, Ind. Filed Feb. 9, 1909.

Direct fuel injection into the combustion chamber of oil engines has become prominent of late, especially in aeronautic motors, as this method, dispensing with the carbureter, has been used on the Wright motors and on several foreign eight-cylinder machines. The device under consideration is positively operated by an eccentric and provides means for varying the charge considerably. It consists of three chambers, the inlet, the measuring, and the outlet, with valves between the first and second and



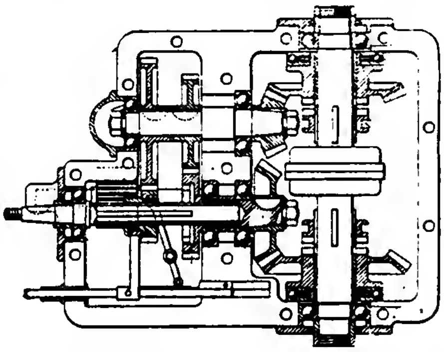
McCarty's Fuel Measuring Device

the second and tbe third, all ingeniously operated by the same eccentric. A movable plunger is fitted in the measuring chamber to vary its capacity.

Issue of Sept. 14, 1909

933,870. Change-Speed Gearing—Austin M. Wolf, New York City. Filed Nov. 13, 1908.

Mr. Wolf's gear, a four-speed selective one, is of the double bevel gear type, suitable for use on cars with double-chain drive or on the rear axle of shaft-driven cars. The two opposed bevel gears on the cross-shaft are normally free, but can be locked to the shaft by jaw clutches. There is but one sliding gear, which has three positions. That to the left gives the reverse; the central

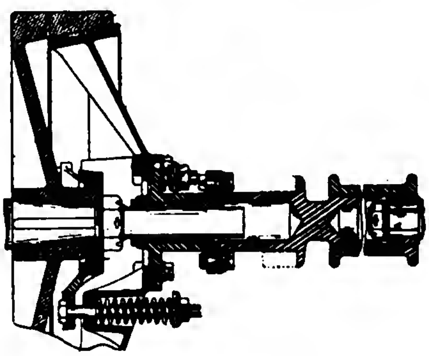


Four-Speed Transmission—Double Bevels

position gives the first and second, according to which of the bevel gear pairs are used, and in the same way the position to the right gives the third and fourth. The power is transmitted through two pairs of spur gears on the second, through one pair on the first and third, and through none (direct drive) on the fourth. Tbe only objection is the number of shafts and gears revolving idly.

934,043. Coupling for Power Transmission—Howard E. Coffin, Detroit, Mich., assignor to the Chalmers-Detroit Motor Company. Filed Nov. 6, 1908.

A sliding coupling to be used between the clutch and the change-gear of an automobile

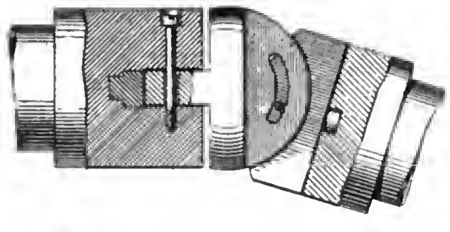


Chalmers-Detroit Cone Clutch

forms the subject of this patent. The specifications call for a member detachably secured to the clutch-sleeve forming an extension thereof beyond the clutch spindle, no longer than the distance between the end of the clutch spindle and the primary gear shaft, the rear end of the extension forming the male member of a flexible coupling. and a coupling sleeve telescoping over the end of the extension and the end of the gear shaft. The object is to enable the clutch to be removed without disturbing the engine or change-gear.

934,140. Universal Joint—Daniel Corcoran, Yonkers, N. Y. Filed Aug. 14, 1908.

The shaft ends are rounded and slotted across their faces, and carry between them

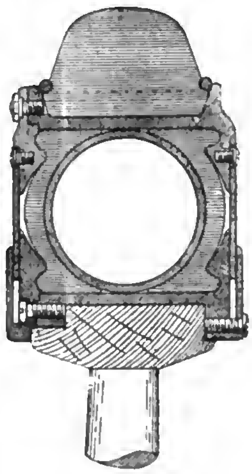


Flanged Disc Type of Universal Joint

a disc with flanges on either side which enter into the slots. As the flanges are in perpendicular planes a universal motion is allowed. The joint is held together by annular slots in the flanges through which pass pins supported in the shaft ends. The turning effort is taken by the flanges, acting in shear. The joint seems especially adapted to use in cases where an Oldham coupling is usually specified; in fact, it seems to be really an adaptation of this form of coupling to give a greater possible range of angular movement.

Issue of Sept. 21, 1909

934,472. Tire—John S. Stevenson, Detroit. Filed Dec. 23, 1907.



New Cushion Tire

This tire arrangement is somewhat similar to a number of the tires brought out in France by the last tire and wheel trials, in that it consists of a solid tire mounted upon tbe exterior of a sliding member, the latter carrying within itself a resilient tire, either pneumatic or cushion, which limits the yield of the solid exterior tire and the slidable felloe. Except for the contact of the yielding (and from its nature, soft) rubber member with the metal all along its side, the design seems to possess merit, at least, for heavy vehicle purposes. The flaw in the construction seems to lie in the large distance from the wooden felloe, which is the real support, to the outer solid tire, which is the point of application of all road stresses. In other words, the lateral strength is small.

934,547. Braking Means for Automobile Vehicles—Arthur Krebs, Paris, assignor to La Société Anonyme des Anciens Etablissements Panhard et Levassor, Paris. Filed Feb. 15, 1908.

This is the well-known Panhard braking device, which consists of additional cams mounted upon the exhaust camshaft. The latter is slidable longitudinally, so that the auxiliary cams may be brought under the valves. When so located, the exhaust valve is opened very little or not at all, depending upon the position of the cam, which is of varying contour. In this way the exhaust gases are retained in the cylinders, and the power is expended in pumping them.

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, OCTOBER 7, 1909—CHICAGO No. 15

THE AUTOMOBILE

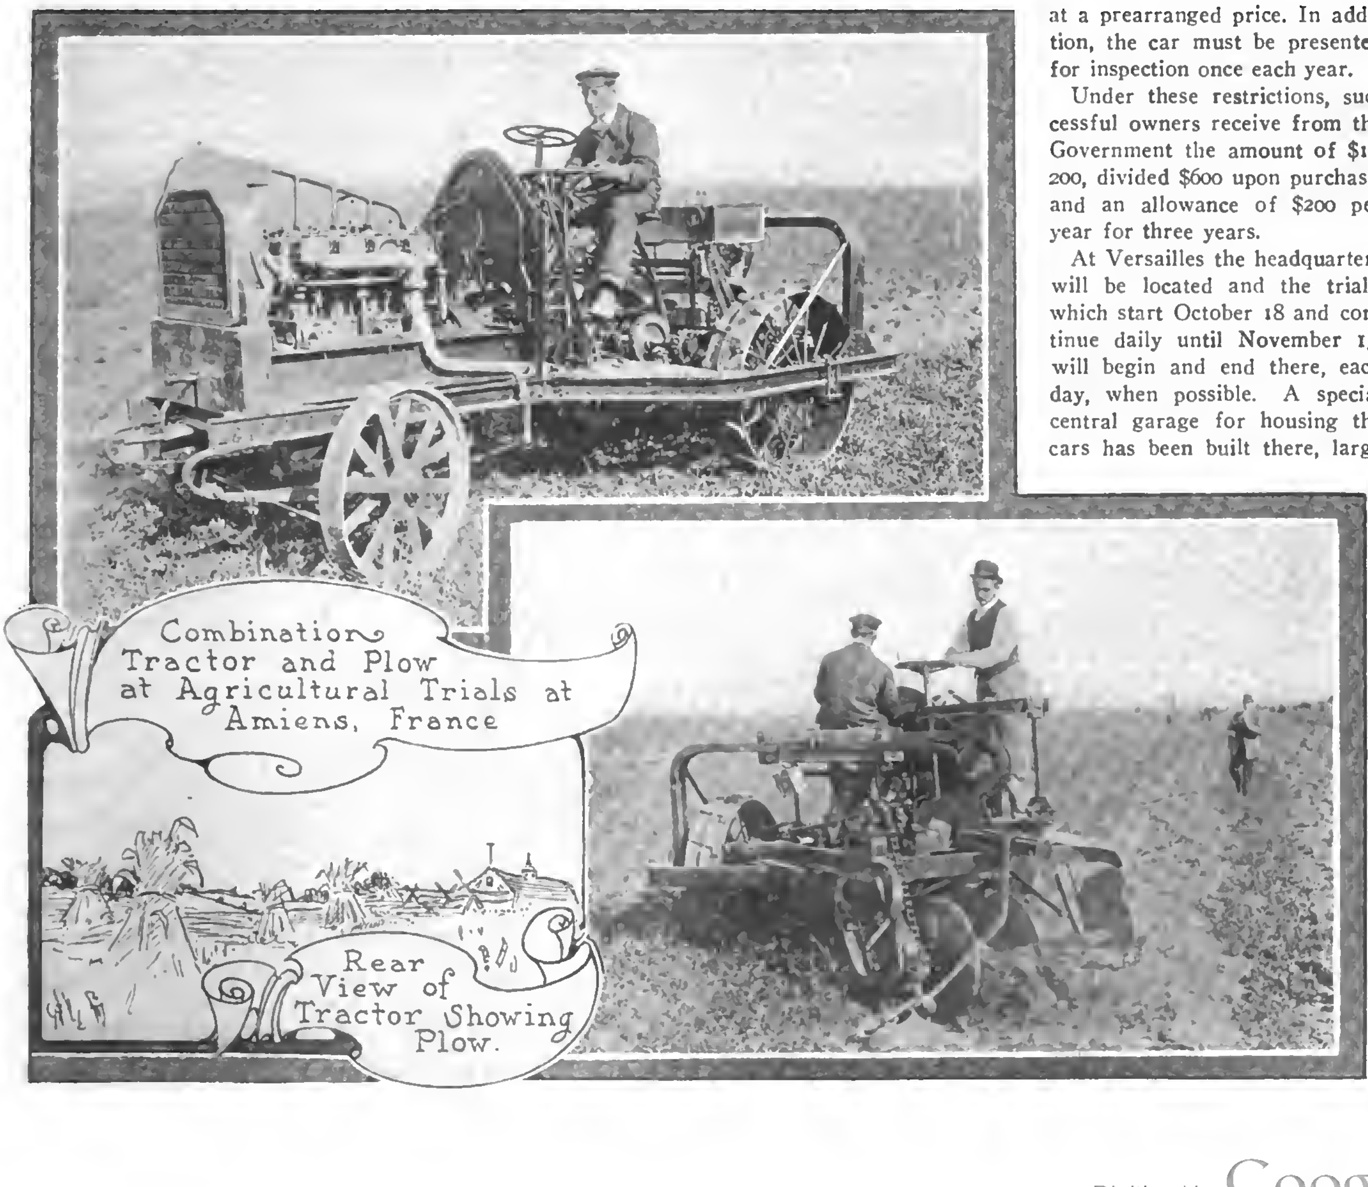
57 ENTRIES IN FRENCH VEHICLE TRIALS

AMIENS, FRANCE, Oct. 1—Spurred on by the prospect of government subsidy in addition to the natural and usual advantages accruing to a winner, the French manufacturers have entered the commercial vehicle trials in such numbers as to insure most strenuous competition. Not only have the lists filled well, but the unusual number of 57 entries have been received. These are divided over the three classes of competition, as well as being spread over the other departments relative to governing power. Thus, of the machines entered, 8 are to be submitted to the War Office trials only, 17 to the Automobile Club's requirements, and the remaining 32 to both.

The trials are to be held jointly by the Automobile Club de France and the French Government, as represented by the War Department. This has necessitated the formulation of two separate and distinct sets of regulations for the conduct of the day's trials. This really makes the competition into two contests daily, and under parallel road and weather conditions, but different rules. In addition to formulating a separate set of rules, the War Department has announced a schedule of subsidies to be paid to owners of vehicles which meet with the department's approval as well as with success in the trials. These subsidies are, of course, given subject to the government privilege of buying the car in case of war, at a prearranged price. In addition, the car must be presented for inspection once each year.

Under these restrictions, successful owners receive from the Government the amount of $1,200, divided $600 upon purchase, and an allowance of $200 per year for three years.

At Versailles the headquarters will be located and the trials, which start October 18 and continue daily until November 15, will begin and end there, each day, when possible. A special central garage for housing the cars has been built there, large



Combination Tractor and Plow at Agricultural Trials at Amiens, France

Rear View of Tractor Showing Plow.

enough to contain all of the cars entered, and fitted with all necessary facilities for doing work upon them.

There are three principal classes for competition, but each class is subject to a further subdivision. The classes are: motor trucks, road trains, and omnibuses. The first is divided according to carrying capacity into various classes, from 880 pounds on up to 6,000 pounds. The second main class has these subdivisions: tractors, freight trains exclusively, and passenger trains. Then, the last class has three sub classes, nemly: carrying capacity of from 6 to 10 passengers, 11 to 20 people, and above 20.

Daily trips will be made over two courses, one measuring 62 miles in length, and the other 93 miles. This takes the competing vehicles over all kinds of bad roads, hills, and through conditions intended to test them out very thoroughly. On the third day, a long trip is to be made to Clermont-Ferrand by easy stages, where the cars will be placed on exhibition, returning later to Versailles to continue the tests.

Added interest will be brought out by the compulsory variation in fuels, alcohol, benzol and gasoline being used in turn, and the results with each being carefully noted. Thus, from October 18 to 31, gasoline will be used; from November 2 to 6, carbureted alcohol will be substituted, and for the concluding week, November 8 to 15, the fuel employed will be benzol.

How much of the French excellence in this form of vehicle is due to mechanical superiority and how much to clever exploitation is very hard, if not impossible, to determine, but it is a self-evident fact that the various makers, exploitation to the contrary, are both ready and willing to enter into public competition to prove their assertions. Never has a trial been so carefully planned out, and so many features of the contestants' comfort catered to in advance. In response to this careful and able planning, the promoters (if the Club and the Government can be called that) have been rewarded with the largest and best entry list ever received. Among the entries are the following high class makers, the number of cars entered by each one being given also: Aries, 4; Berliet, 4; Berna, 1; Clément, 4; Cohendet, 2; De Dion-Bouton, 5; Delaugère, Clayette et Cie, 4; Desmarais et Morane, 4; Krieger, 3; Lorraine-Dieterich, 4; Malicet et Blin, 3; Panhard et Levassor, 4; Peugeot, 4; Société de Poids Lourds, 2; Saurer, 5; Schneider et Cie, 2; Vinet, 2. With this kind of competing vehicles, many of the figures set last year, and in previous trials should be wiped out. Thus, the figures for heavy vehicle economy made in 1905 by a Daimler, carrying 6.8 kilos, at an average of 20.8 km per hour, on .035 litres of gasoline per ton-km, should be displaced. The trials should bring out construction novelties.

SOME SUGGESTIONS TO TOURISTS

A consul who has long resided in a non-English-speaking country and who has seen many instances where misunderstandings and misconceptions, with subsequent unpleasant contingencies which could have been avoided by patience and courtesy, offers the following suggestions to tourists and travelers:

When traveling through a non-English-speaking country, one should remember that it may be extremely difficult for the people to understand what the tourist wishes. Neither should one forget that the customs, tastes and traditions of the people differ from that of the tourist, as a consequence of which the multifarious things and customs which he encounters do not coincide with those to which he has been accustomed. Nor should one expect to be served as punctiliously and satisfactorily as at home, considering his varied environments. In fact, anything which one finds abroad should be given due consideration and, in case of any complaint, an effort made to remedy the matter in a reasonable manner.

This can be easily done through the use of a little tact and common sense. Courtesy is something the public have a right to expect of a tourist. The tourist expects it from all those with whom he comes in contact and almost invariably receives it; then why should he be reluctant to reciprocate this kind attention and friendly disposition on the part of the foreigner?

Through courtesy and its inherent subsidiaries more than through any other characteristic a traveler may not only more easily raise himself, his people and his country in the estimation of the foreigner, but he thereby places himself in a position oftentimes to obtain many favors and concessions from the people among whom he is sojourning which might otherwise be graciously refused.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers. Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 21-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

FOREIGN

Nov. 12-20.......London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

AMERICAN

Races, Hill Climbs, Etc.

Oct. 5-9..........Danbury, Conn., Stock Car Races in Connection with Danbury Fair.

Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City M. C.

Oct. 8-9..........Louisville, Ky., Endurance Run, Louisville Automobile Club.

Oct. 15-16........New York City, Brighton Beach Track, 24-Hour Race (postponed from September 24), Motor Racing Association.

Oct. 23...........San Francisco, Road Race, Automobile Club of California.

Oct. 28-30........Dallas, Texas, Three-Day Track Meet, Dallas Automobile Club.

Oct. 30...........Vanderbilt Cup Race, Long Island Motor Parkway, Motor Cup Holding Company.

Nov. 8-9.........Savannah, Ga., Georgia Highway Reliability Contest to Atlanta, Savannah Automobile Club.

Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.

Nov. 20-21.......New Orleans, Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary-Manager.

Nov. 22...........Denver, Col., Start of "Flag to Flag" Reliability Run. G. A. Wahlgreen, Manager.

Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

NEW YORK CITY HAS A LOOK AT AERIAL TRAVEL

WILBUR WRIGHT firmly established himself as the popular hero of aviation by two marvelous flights at New York during Hudson-Fulton week. From Governor's Island, on September 29, he sailed out across the bay and circled the Statue of Liberty; and on October 4, again rising from the little island at the lower tip of Manhattan, he took his way up the Hudson River to Grant's Tomb, passing over the warships at anchor, and returned to the starting point calm and smiling as ever. It was done so easily and so quickly that the cityful of spectators stood in a daze, almost forgetting to cheer. Then, at the very moment of starting on another flight, which would have thrown the first two into insignificance, a cylinder head of the motor blew out, and the crowds waited in vain. But the practicability of aerial travel had been demonstrated as never before in the presence of half a million witnesses.

The Hudson-Fulton committee began negotiations with Wright and Curtiss in August, and secured the signatures of both aviators to contracts binding them to make flights in the vicinity of New York. A large tract of made ground on Governor's Island, the military station, was set apart as an aviation field, and sheds were erected to house the aeroplanes. Wright arrived in New York September 19, and Curtiss two days later. Both quickly had their machines ready, but rain and high winds prevented the trials for several days. Curtiss was the first to take the air. At 7 A.M., September 29, he made a short flight about one minute in duration, returning to his starting point without trouble. He postponed further attempts to fit a new propeller.

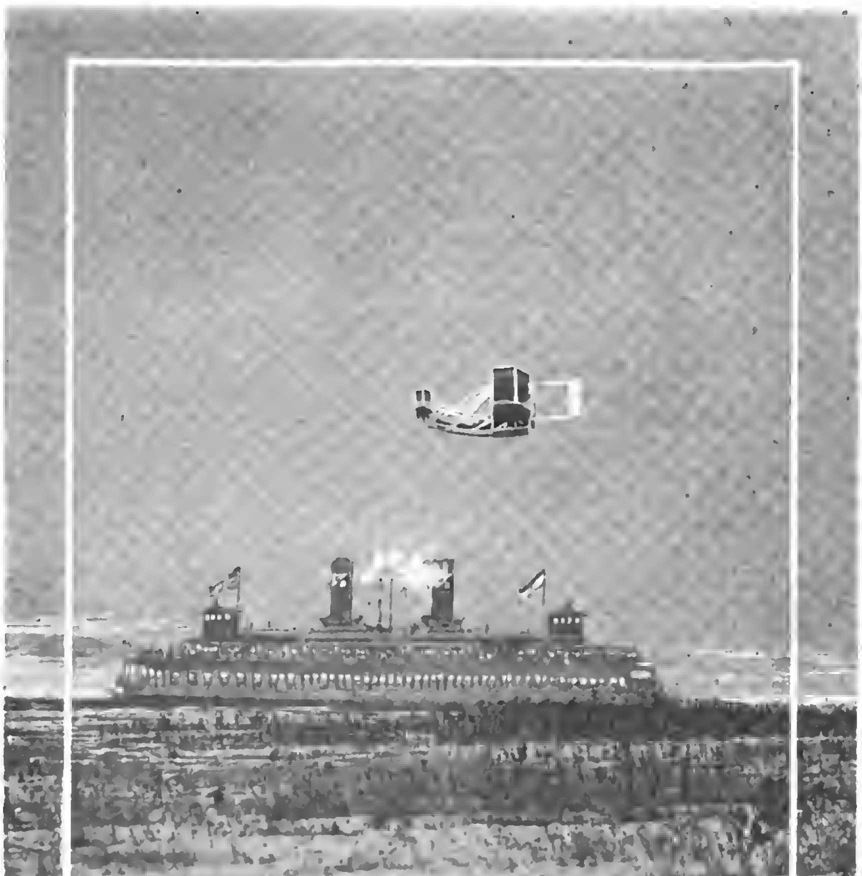
Wright arrived on the island soon after the Curtiss machine had been taken back to its shed, and after a short inspection brought out his flier. Pointing the machine directly into the wind, he ran lightly along the starting rail and went easily into the air. Two circuits of the filled-in ground were made, and then the machine headed straight out over the water. It flew over two tugs at a height of 100 feet, turned up Buttermilk Channel, and coming abreast of the upper end of the island, turned back again in full view of the crowds on the Battery sea wall. It landed rather abruptly, but without damage, having been in the air altogether 7 minutes 10 seconds. Then instead of taking the machine back to the shed, Wright had it again placed on the rail, and after an hour spent in looking it over, he climbed into the seat. The start was even quicker than before, and after a short circuit of the ground at a height of 30 feet, he turned out over the bay, headed straight for the Statue of Liberty. The crowd set up a mighty shout.

With three or four long rolls, like a ship at sea, the flier rose some 200 feet in the air. It sailed smoothly on; came abreast of the statue, and passed it. Over the narrow strip of water between Bedloe's and Ellis Island Wright brought it around in a magnificent sweep, his silver planes inclining gracefully. He circled back to the goddess on the south side, passing over the breakwater of the island and within twenty-five feet of the statue, at the height of its waist. At this moment the *Lusitania* came in sight, outward bound down the bay. Her decks were black with passengers, but the roar of the whistle drowned their cheers. The flier crossed her bows only 150 yards distant. Six minutes 40 seconds after the start the aeroplane settled gently on Governor's Island, and Wright stepped out, clearly pleased with his trip.

Late in the afternoon the flier was again brought out. The wind was now blowing twenty miles an hour, and the spectators could not believe that Wright was considering another ascension in such weather. Nevertheless the aeroplane was set on the rail and started off. It made three circles over the island and the bay to the south, often heeling over sharply in the wind, and landed without mishap. Many thought this flight the most remarkable of the three.

A period of unfavorable weather prevented further trials till October 4. That day, which was to be the climax of the week, dawned bright and clear; flags drooped from their staffs, and from the chimneys smoke rose in straight columns. It had been announced the day before that a flight was probable, and the city was on the lookout.

The aeroplane left Governor's Island at 9:53 a. m., and immediately headed out over the water. For a time it was lost from the sight of those on the island in the smoke of a harbor boat; when it reappeared it was bound straight up the Hudson at a height of 75 feet. The whistles of



Wright Starting from Governor's Island on Memorable Flight

Wilbur Wright and His Epoch-Making Aeroplane—The Canoe Was Carried in Case of Fall into the Hudson River

tugs and ferryboats set up a deafening chorus, warning the whole city. Little work was done downtown that morning. Opposite the Singer tower Wright rose 200 feet in the air, but at Fulton street he swooped down, resuming a straight course at about half the former altitude and nearer the Jersey shore. Riverside Drive was lined with spectators as he passed, and the sailors on the foreign warships turned out to man the yard-arms. He had now come over to the New York side, and passed Grant's Tomb at 10:13, only 200 feet off shore. He made his turn around the British cruiser *Drake,* a thousand feet to the north, and returned on the Jersey side. Going down, he had the wind in his favor, and at 10:26:33 he alighted on Governor's Island. The distance was 20 miles, and the time 33 minutes 33 seconds.

Preparations were immediately started for another flight in the afternoon, which was to be up the East River, under or over the bridges, and possibly clear around Manhattan Island. Just before 4 o'clock the motor was started, and Wright turned aside for a moment. Suddenly there was a muffled explosion, and a piece of metal shot through the upper plane and fell within a few feet of the aviator. It was the head of the forward cylinder of the motor. The whirr of the propellers died down. Wright glanced at the ruin; then dropped his arms to his side and turned away. The flights were over.

Dirigibles Fail to Fly to Albany

The dirigibles of Capt. Baldwin and George Tomlinson, which were to race up the Hudson to Albany for a $10,000 prize, both failed signally. After several postponements, they started, September 29, from the station at 120th street and Riverside Drive, near Grant's Tomb. Capt. Baldwin's steering gear broke after he had gone four miles, and he fell in the river. Tomlinson got as far as White Plains, and came down in a field.

Captain Baldwin's Dirigible Starting from Riverside Drive, September 29, for Albany, in the $10,000 Prize Race

SELDEN DECISION BRINGING STARTLING RESULTS

Eight Big A. M. C. M. A. Concerns Will Be Affiliated with the A. L. A. M., with More to Follow—Ford May Continue the Contest—General Motors Company Situation in Doubt

DEVELOPMENTS of the past few days and attendant possibilities of the near future indicate that the recent Selden patent decision will bring about startling organization changes in the automobile industry. Following the decision of Judge Hough came the information that the Association of Licensed Automobile Manufacturers would undoubtedly take a broad view of the situation and not attempt anything which might prove detrimental to the industry as a whole. There has seemed to be a realization on both sides of the patent litigation that the present extraordinary demand for automobiles is inducing manufacturing preparations of such proportions as to arouse fears of a dreaded over-production and more or less disaster to all concerned, including those firms who bore the brunt of experimental expenses in the early days, when the making of motor-driven vehicles proved somewhat unprofitable.

That Important Conference at Buffalo

First of the moves in a new alignment of concerns was a meeting held in Buffalo on Wednesday of last week, at which were present H. O. Smith, of the Premier Motor Manufacturing Company and chairman of the A.M.C.M.A. committee of management; Benjamin Briscoe, of the Maxwell-Briscoe Motor Company and ex-chairman of the A.M.C.M.A. committee of management; C. G. Stoddard, of the Dayton Motor Car Company and vice-chairman of the same committee; R. E. Olds, of the Reo Motor Car Company; Charles Lewis, of the Jackson Automobile Company and another member of the committee; William Mitchell Lewis, of the Mitchell Motor Car Company, besides Mr. Mathews, of the Jackson company, and Mr. Bates, of the Mitchell company.

It was a natural sequence that a representative of the A. L. A. M. should be more or less present during the somewhat prolonged session. One question propounded to him was whether the A. L. A. M. would take in the A. M. C. M. A. as a whole, and the reply was that each company would have to make separate application and fulfill the conditions imposed.

New Conditions of Licensed Membership

Covering all cars delivered and sold since 1903, new members will be asked to pay eight-tenths of one per cent., same being based upon the list prices of the cars at the time of sale. It is understood that the Licensed representative had power to offer specified conditions, but no authority whatever to change them in any particular.

These concerns are understood to have decided at the Buffalo meeting to qualify for A.L.A.M. membership:

Maxwell-Briscoe Motor Company
Reo Motor Car Company
Premier Motor Manufacturing Company
Mitchell Motor Car Company
Dayton Motor Car Company
Regal Motor Car Company
Jackson Automobile Company.

It was only a couple of weeks ago that the Willys-Overland Automobile Company vaulted the fence into the Licensed field by absorbing the Toledo Motor Company, which held a Selden license. This gives a total of eight A.M.C.M.A. concerns on the Licensed roll call.

Respecting future applications from the A.M.C.M.A., only such other companies as may be recommended by the above concerns, and only those which have built cars on a considerable scale, will be considered for membership by the A. L. A. M.

To Prevent Possible Over-Production

Once the A.L.A.M., after a reasonable length of time, concludes its consideration of new members, the indications are that it will proceed against all the remaining concerns, and insofar as it is possible so to do, will prevent the many newcomers from an over-production which would flood the market disastrously.

In a letter sent out by the chairman of the A.M.C.M.A. executive committee following the meeting at Buffalo, the concluding paragraph read as follows:

"It seems to be the general opinion of those present (referring to the Buffalo meeting) who had conferred with their patent counsel that the hearing on appeal (referring to the Selden case) would probably occur at a comparatively early date, and, if confirmed, the position of the Licensed association would be such that it would control the situation."

If this statement represents the present general view of the unlicensed makers, in the face of all the legal talent that has been employed in the Selden case, it is not difficult to understand why eight important makers have already decided to enter the Licensed fold.

What Henry Ford Will Decide to Do

Up to the time of going to press the only news available from the Henry Ford camp was to the effect that his company would continue its independent course, though both the head of the concern and Vice-President James Couzens have had various conferences in New York City, where all the leaders of the industry are now gathered.

An impression prevails that Mr. Ford will hold out, rather than pay at this time the large sum which would represent back royalties.

If Ford appeals, it is contended by some, the measure of damages cannot be more than the eight-tenths of one per cent., which is the basis of agreement as between the Licensed association and the companies already as good as taken in. Others say that the measure of damages will be more, because the royalty has been all the way from five per cent. down, it having been reduced from time to time. But it is pointed out that there were but few Ford cars built during the time when the higher royalty was in vogue, and if Ford puts up a fight, all he has to risk is the cost of the appeal and defending the suit for damages which must be brought before the Licensed association can spend any of Ford's money. This will be true if it is a fact that the measure of damages is now fixed by the agreements made with the companies that have accepted the Hough decision as final.

The Situation of the General Motors Company

A decidedly interesting phase of the present situation relates to General Motors, now comprising Buick, Oldsmobile, Cadillac, Welch, Rainier, Oakland, Reliance, and Rapid, with W. C. Durant as the man in the saddle. It will be remembered that last Winter, when the combine of which he is the head only included Oldsmobile and Buick it refused to continue paying royalties, since which time a suit has been pending in the courts. Mr. Durant is on the ground, but whether he wants to renew his Licensed affiliations or whether he will be permitted to do so even if he is willing, are questions yet to be answered.

Elmore, Two-Cycle Winner, Only Survivor with Clean Score

Renault, the Foreign Car Participant, Winner of Its Class

12 Pullman Which Was Most Successful in Division 3

Maxwell "Q" Which Took the Honors in Division 2

TWO-CYCLE ELMORE

WASHINGTON, D. C., Oct. 2—Two-cycle Elmore survived the Munsey reliability contest with a flawless record, thus winning the sweepstakes prize for the car making the best score in the tour, and at the same time winning the trophy offered in the $2,001 to $3,000 division. The car was driven by Frank Hardart, Jr., son of the entrant, and hailing from Philadelphia. While a protest has been filed by Ray W. Harroun, it is far from probable that the technical committee will have its findings revised by the contest board of the A. A. A. Harroun drove No 30 Marmon, which was penalized only seven-tenths of a point. Here is the complete list of winners:

Class.	Points.
$4,001 and over...	
No. 28, Renault	4
$3,001 to $4,000	
No. 21, American Simplex	.9
$2,001 to $3,000	
No. 36, Elmore	.0
$1,251 to $2,000	
No. 12, Pullman	62.3
$851 to $1,250	
No. 9, Maxwell	29.
$850 and under	
No. 7, Ford	6.

The trophy in division 3 was originally given to the Crawford. but the fact that a front wheel was replaced the first day, which did not appear on the observer's card, gave the car a greater penalty than first appeared. This made No. 12 Pullman the winner of this division, but the award of the trophy to this car has been protested by the Carter Motor Car Corporation, of Washington, entrant of No. 5 Washington. The basis of this protest is that the Pullman, which sustained a broken spring, could not replace it for $2, as claimed. No. 5 Washington had 68 points against it.

The entry of the travel-stained motorcade into the National Capital was on the order of a triumphal progress from the time the limits of the district were reached until the cars drew up in front of the Munsey building. A parade was formed on the outskirts of the city with a quartet of United States Army buglers in the van. Half a hundred escorting cars followed the 25 cars which had participated in the run, and when Pennsylvania avenue was reached the crowd was so dense that the lines of police who were on hand to keep the crowd in order had all they could do to maintain a passageway for the procession. Each car and driver was lustily cheered by name as it finally checked in and was sent off to the official garage, where it was immediately put through the

PERFECT SURVIVOR

brake, clutch and other tests preliminary to the final technical examination. The "can't-lose-me" Autocar truck reported at 8.30, having left Philadelphia three hours after the run.

Wednesday night the tourists were entertained at Belasco's Theater by "The Yankee Girl." Thursday's program included a monster floral parade in which the contesting cars with their mud and grime shared interest with the many beautifully decorated machines which contested for prizes. From 8.30 until midnight the tourists were entertained by a smoker in the red room at the New Willard Hotel, during which the results of the run were announced and trophies presented.

The tour was a big success in many ways notwithstanding the bad weather encountered during the greater part of the time. The rain and mud played havoc with some of the cars, and of the original twenty-five starters but twenty of them completed the tour. The tourists received an ovation in Philadelphia and Baltimore on the return trip and their entry in Washington was the occasion of the greatest outpouring of people since the inauguration.

Why Penalties Were Imposed

The Ford received a total penalization of 6 points, of which 1.4 points were sustained for carbureter trouble the first day and .3 point for stalling the motor that day. On the second day .2 point penalty was again levied for stalling the motor twice and .1 point for adjusting the carbureter. In the technical examination the car lost .2 point for a loose right rear fender bolt and loose bolts on the right and left transmission arms; .5 point for a loose extension muffler pipe; .1 point for a loose nut on the driving shaft; .2 point because the muffler cut-out stuck open, and 3 points because the front wheels were loose.

No. 29 Hupmobile, the other entrant in division 1, was listed as finishing as a non-contestant, but the driver objected to this procedure, stating he would prefer to have the car's score made up rather than have it placed in the non-contestant division. The Hupmobile sustained an accident coming out of the garage at Willimantic, which made it late in reaching Washington. R. W. Keeler, the driver, drove the car from Willimantic to Washington without stop, finishing at 10.30 o'clock, September 30. Referee Trego is now figuring out his score.

The model Q Maxwell, winner in division 2, received a total penaliza-

American Simplex, a Two-Cycle Performer, Prize-Taker in Division 5

Ford, Winner of the Smallest Class of the Contest

The Autocar Delivery Wagon Which Finished Strong

All Survivors Participated in the Floral Parade tion of 29 points. This car had a perfect score up to the seventh day, when Lambert stalled the motor, receiving .1 point, while on the ninth day .2 point was received for a loose magneto wire. In the technical examination .5 point was assessed for a loose right front wheel; .1 for a loose left front lamp bracket; 4 points for the coming off of a rear axle truss rod and 6 points for work on same; .1 point for loose muffler extension; 12 points because the rear universal joint was badly worn and 6 points for work on same.

The Reo in this division lost 94.3 points, of which 27 points were lost on the road and the remainder in the final examination. The latter penalties consisted of 20 points for play in the steering wheel; 34 points for a wornout steering knuckle and 12 points for work on same; .2 point for lost radius rod bolt and .5 point for replacing same; .1 point for a loose right rear spring clip and .5 point because the drive chain was too loose. The car was a 1908 model that had been driven 15,000 miles by its owner.

No. 12 Pullman, winner of division 3, lost 62.3 points; the Crawford, 71.9 points; No. 5 Washington, 68 points. No. 31 Washington lost 438.7 points, divided as follows: .1 point for stalling motor the first day; .1 point for tightening pump the second day; .2 point for stalling the motor twice and 31 points for being late in the final control the third day; 358.1 points for work done and for being late the fourth day; .3 point for stalling motor three times and .1 point for work on rear mudguard the seventh day; .1 point for stalling motor and .4 point for tightening front fender the ninth day. This car lost 48.3 points on the final examination for play in the steering wheel, loose front and rear mudguards, broken rear axle truss, crushed muffler exhaust pipe, loose magneto ribs, play in the fan bearing and a leaky water-pipe joint.

No. 32 Washington received 1,555.6 points, 1,451 of which were received the fourth day, when accidents to the car delayed its arrival in Boston many hours. The car lost 74.6 points on the final examination.

In division 4 the Chalmers-Detroit drew a total penalization of 51.2 points, of which 49.2 were the result of the technical examination and 2 points for stalling the motor twice and work done on the road. The technical examination developed a penalty of 7 points for a broken right front mudguard brace, .2 point for loose spring cleats; .1 for loose right front fender; .5 point for play in the left front wheel; .1 point for loose fan bearing; .6 point for loose rear fenders; .2 point for lost nut off fanshaft pulley, 35 points for a badly broken subframe in the rear of the transmission; .1 point for loose right front engine arm bolts.

Six and three-tenths points was the score of the Spoerer. On the first day this car was penalized .3 point for oiling the clutch, while on the seventh day 3.2 points penalty was incurred, of which .8 point was for removing wires from and adjusting the magneto; 1.6 point for adjusting the timing rod and .2 point for cleaning the carbureter. On the ninth day the motor was stalled twice, which added .2 point. In the technical examination the car lost 2.6 points.

The Corbin finished with 662.1 points against its record. No. 20 Winton lost 5.5 points, of which 1.1 point were sustained on the road and 4.4 points in the technical examination. The Marmon lost .6 point in the technical examination and .1 point for work on the road. No. 13 Pullman was penalized 10.7 points, of which 9.9 points were on the final examination.

The American Simplex, winner of division 5, lost but .9 point. On the second day the driver stalled the motor, which cost .1 point. In the technical examination the car lost .8 point.

The Renault came through with but .4 point marked against it, winning division 6. The penalties consisted of .1 point for adjusting hub cap, .1 point for loose spring cleats, .1 point for loose leather boot on universal and .1 point for loose transmission oil stud.

The Maryland and Columbia finished as non-contestants. Both received severe injuries that put them out of the running. The Matheson was disqualified in New York when the driver put the car in the Matheson garage unattended by an observer.

The two Croxton-Keetons were withdrawn, No. 17 at Willimantic and No. 16 in New York; No. 37 Pullman was withdrawn in Albany and the Selden in Philadelphia.

Details of Harroun's Protest

The protest filed by Harroun is set forth as follows:

"The penalizations against the Marmon, in my opinion, were on technicalities which should have been considered negligible, considering the amount of leeway given all contestants. The Elmore, in my opinion, finished the contest with defective brakes, which was demonstrated by the fact that this car ran into the Marmon when approaching Washington. During the excitement of the moment the driver of the Elmore made the remark that he 'had no brakes' as his excuse for the incident. Furthermore, the Elmore had a very noticeable dish in the left front wheel, showing that the spindle was badly bent. During the latter part of the tour the Elmore had a bad knock under the bonnet, which was very noticeable when the car was standing still and the engine running.

"I claim that the penalization given me of 0.1 point on the road score for removing and replacing the filler cap of the radiator while the car was in motion; 0.5 point for a very slight perceptible shake in the right front wheel bearing, and 0.1 point for what I consider an allowable play in one spring cleat, should not have been made against the Marmon."

Why the Croxton-Keeton Cars Were Withdrawn

Editor THE AUTOMOBILE:

The Croxton-Keeton entries in the Munsey reliability tour went through as far as New York City on the return with the following scores, as you have undoubtedly noted: The 45 horsepower German type arrived at New York with a perfect score, and the 30 horsepower French type was penalized four and one-half points for breaking an unessential bolt.

Our vice-president, Mr. Bernhart, was threatened with a very serious illness on account of the wet weather encountered, and at the arrival of H. A. Croxton, the president of our company, conditions were such in our New York branch that they demanded the immediate use of these entries for demonstration purposes.

Having covered all but the last two days of the reliability run, we had proved all that we wished to prove in respect to endurance and speed under unfavorable weather conditions and rough roads, and as they were the only cars available for demonstration in our New York branch, Mr. Croxton gave orders for an immediate withdrawal from the tour, and placed the cars at the disposal of J. P. Stoltz of the Croxton-Keeton Motor Company of New York City.

Massillon, O. THE CROXTON-KEETON MOTOR CO.,
S. W. CROXTON, JR.,
Publicity Manager.

Floral Parade Will Be an Annual Affair

Washington turned out en masse Thursday to see the automobile floral parade arranged by the Chamber of Commerce. The great outpouring of people to witness the pageant was a revelation to the promoters of the parade, and it has been decided to make the event an annual affair.

The grand marshal of the parade was W. D. West, president of the Automobile Club of Washington. The cars that competed in the Munsey reliability tour headed the parade, and the drivers received an ovation all along the line.

The sweepstakes prize, a $600 rose bowl, donated by the Chamber of Commerce, was won by a float entered by employes of the Naval gun factory. The vehicle was a 5-ton Studebaker truck, which was decorated with American Beauty roses and laurel leaves.

The first prize for cars decorated with natural flowers only was won by Harry Wardman, whose Pope-Toledo was designed as a Venetian gondola and decorated with pink and white chrysanthemums. The rose-decorated Waverly electric of Mrs. T. B. Spence was an easy winner in the class for flower-decorated electric machines with women drivers. The car was fashioned in the shape of a huge basket filled with pink roses. The first prize for the handsomest floral decorated cars in the gasoline division was won by the entry of the Auto Livery Co. The Washington *Post* carried off the prize for the most unique float. A big Packard truck was utilized to form the upper half of the globe, upon which were traced America, Europe, Asia, Africa and the north pole in Southern smilax.

Special Machinery Used In Making Automobiles

By Thos. J. Fay

QUALITY is measured, not only in terms of the life and efficiency of a unit, but with reference to the interchangeability of parts, so that when repairs are to be made, the delay will not be long. One other point: a repair part, when substituted for a worn out part, should fit so nicely that the recovered situation will be as good as new.

It is one thing to make one good automobile, but it is quite another matter to make them in quantity and have them all alike, with every part so closely held that repairs can be made by the simple expedient of sending for the part and inserting it in place when it is received without any machining or fitting.

The first difference to be noted as between "foreign" cars and the home product lies in the very chance that no two of them will be alike. This is due to a surplus of cheap labor, and the absence of jigs, special tools and gauges. It is generally well understood that special tools reduce the labor account, and in countries where labor is cheap this way of going about the manufacture of automobiles is ignored in order to save the enormous cost of the special tools.

One important point is overlooked—interchangeability is absent—and no matter how good the material may be, or how well a car may run, if the parts cannot be removed when broken and then replaced the cost of making repairs will be high. Even this phase is not of such great importance abroad, for if there is plenty of cheap labor to do the original work there is also a surfeit of the same class of labor to make repairs. The change in scene from Continental Europe to the United States, with far inferior roads, changes the situation very much. Since the liability to accident is greater, more stress must be laid upon the matter of replacement of damaged parts. In this respect the cars built on the other side by means of the over-plentiful cheap labor are at a disadvantage. The best of materials avail little if repair parts show the human failing of differing slightly from the piece originally used. So it is that the tendency abroad to economize on shop tools and special machinery while the supply of labor continues abundant has brought home to the American manufacturer all the business that he can handle. If but to encourage home manufacturers after their investment of millions in special machinery, cars made on this side should be given the preference.

This is the story of the difference beeween the foreign and American automobiles. Although slightly tinged from their viewpoint by the supposedly superior materials available, it is enough to point out that the American maker who will spend hundreds of thousands of dollars to equip his shop with "duplicating" machinery will be just the maker who will go to Japan, if necessary, for the material requisite to accomplish his task.

Labor Saving Is but One of the Purposes—We hear so much of the labor saving idea that most of us fail to remember that there is a second and stronger reason for using special machinery in a shop. Remembering, however, that it is of far greater importance to be able to duplicate parts than it is to save a little labor, it will be profitable to enter a shop and see how the multiple task is performed.

Take an Elmwood Avenue car, and after a pleasant ride through one of the most beautiful sections of Buffalo a broad expanse of buildings of the most modern "concrete construction" will intercept the line of vision on the right hand side. It is the plant of the Pierce-Arrow Motor Car Company, makers of the Pierce-Arrow. The entrance is imposing, and the uniformed attendant at the entrance will politely direct the visitor to the reception room. The first impression is that the managemen is alert, wishes to consider the comfort of the visitor, but the scheme is far deeper, as we shall presently see. The real inside of the situation is that workmen cannot do the finest grade of work without light, heat and ventilation, and as a matter of fact, the visitor when he enters the reception room is treated with precisely the same consideration as the blacksmith, the machinist and the artist who are responsible for the body creations used on Pierce-Arrow cars. Everywhere is light, with ample provision for heat, and sanitation has a place in the plan.

It might be said this is not relevant to the subject but, really, the first requisite is to have a suitable place to house the special tools and the men who must direct them. In the old days, before pyrometers came into vogue, forges had to be placed in a dark room, in order that the "smith" might be able to judge of

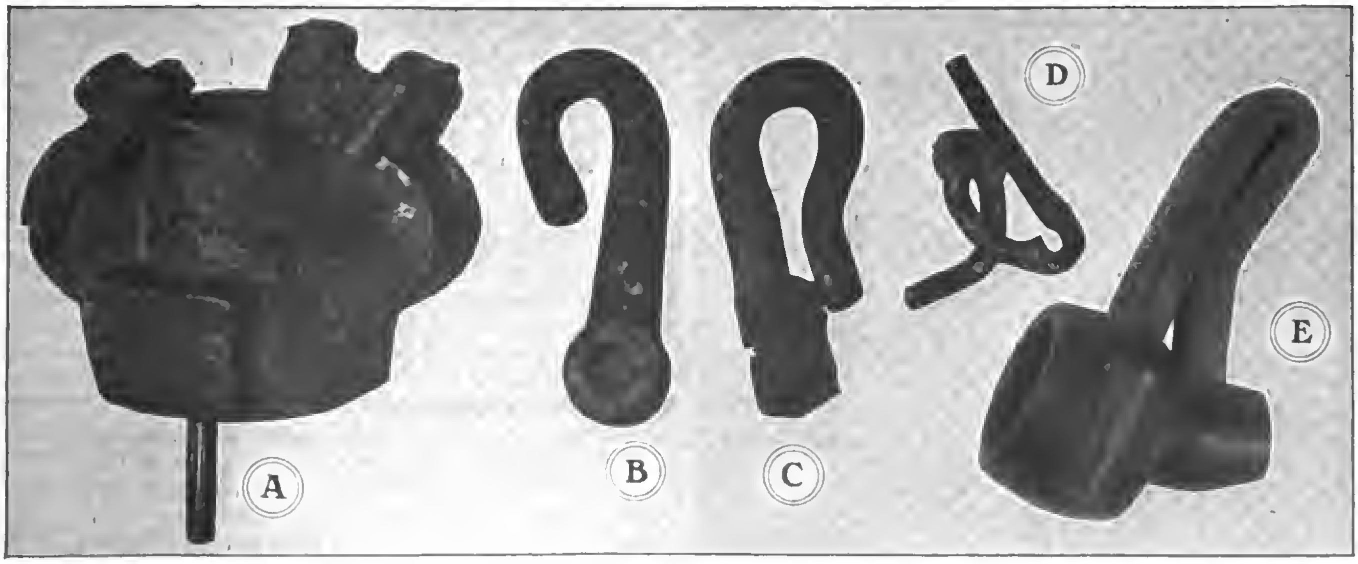

Fig. 1—Drop forgings bent to illustrate the good effect of annealing, and of heat treating in other ways

Fig. 2—Traveling crane used to eliminate dead labor and reduce cost of handling heavy units

the temperature of heated work, merely by the color. With pyrometers to tell the story in a much more accurate way, the dark forge is no longer a necessity, and the level of the "smith" is increased until to-day he is one of the most important men around a plant in which fine automobiles are evolved.

What the Forge is Reduced to—Where once the "smith" fashioned parts to intricate shapes by hand, using a fire, an anvil and a certain showing of muscular energy, the heat treatment of parts is substituted for the most part. The parts are made in dies by drop forging, or in a hydraulic press. As they come

Fig. 3—Moving platform for handling supplies with or without a truck

from the process they are not fit to use, due to the high heat at which they are drop forged, hence they have to be heat treated, which consists of annealing, heating, subsequent quenching, etc., depending upon the quality of the material used and the duty it is to perform.

Fig. 1 shows just such parts, and A represents one which was experimented upon to bring out the point here to be made. An inspection of this part will show that the bent-over arm fractured near the end and developed a fissure besides. This bending-over process was conducted before the forging was heat treated, and just to show that this condition of irresponsibility could be eliminated the forging was then heat treated, after which the arm was subjected to the same bending process, with the result that the part shows no sign of fracture or distress.

Glancing again at Fig. 1, B, C, D and E will disclose more of the results that follow heat treating. In the Pierce plant, in order to uncover the surfaces, all forgings are subjected to a "sand blasting process." This is but a part of the business of the room or department where once the "smith" held domain, and, as the story goes, every part that now enters a car is suitably manipulated. This means that it must be subjected to one or the other of the processes as follows:

(A) Annealed to remove internal stresses.

(B) Cemented, to grow a deep surface coat of carbon, in order that it may be rendered strong and hard of surface, without reducing the dynamic ability of the soft core.

(C) Quenched, in oil or water, according to requirements, to bring out certain qualities.

(D) Subsequently tempered to accentuate kinetic ability.

The laboratory stands in the shadow of the department where parts are heat treated, and the foreman is carefully informed by the chemist as to the composition of the material, in order that the correct temperature will be maintained. A pyrometer tells the manipulator just what the temperature is at all times, and a recording master pyrometer affords, for the benefit of the chief engineer, permanent information in relation to this important matter. Likewise the testing machine is used to determine the degree of benefit derived, and in these several ways the quality of the steel is exactly determined.

Many Parts are too Heavy to Lift—The elimination of common labor, which ranks on the "cost system" as dead labor, is necessary if the product is to be up to a fitting standard and have a price tag which will not be too high. Since many of the parts have to be moved about and are heavier than a machinist or a fitter could be expected to lift, it would require the use of common labor were it not for the presence of traveling cranes, one of which is shown in Fig. 2, which spans the erecting shop and is used to move the units quickly under the guidance of one skilled man, and at the beck of the men who do the work, thus placing one machine of great range and ability at the disposal of the men of skill instead of a horde of common labor.

A traveling crane is not easy to arrange in the loading shed where the freight cars are backed in on a siding to deliver materials. Fig. 3 shows how the Pierce engineers disposed of this rather troublesome matter, and it will be observed that the moving platform depicted is so contrived that materials may be dumped on it, to be moved in or out, or trucks may be run on to the platform and up the incline to the cars outside, or down the incline, to the floor inside.

Insight into Some of the Processes—If the name of the maker is to be on the hub-caps of the cars it is important to have it engraved on in such a way that it will present evidences of taste. It is not possible to have this work done in the foundry by means of letters on the patterns and comply with the requirements. Fig. 4 shows how the work is done in the Pierce plant by means of a machine operated by a man who could not possibly engrave the name on the hub-caps, yet even so, by aid of this ingenious machine the man is enabled to accomplish the task. The process is simple and consists of a platen on which a master engraving rests; a chucking vice holding the hub-cap; a system of parallel motions, so contrived that a pointer which the operator moves over the master plate directs the engraving tool (an end mill suitably ground and shaped) over the hub-cap. The graver imitates whatever figure is on the master plate and all that the workman has to do is to follow the design.

Fig. 4—Process of engraving names on hub caps, thus saving cost of skilled engraver, and producing identical results

More Important Work Done With Equal Ease—In interchangeable work there is no part of an automobile that can be regarded of such great importance as cylinders. They have to be made of cast-gray iron, and they are subjected to high and variable pressures. If they are not interchangeable the cost of a replacement will be very high indeed. Fig. 5 depicts a big multiple milling planer used for facing off the cylinders, and with nine milling spindles so disposed as to accommodate as many milling cutters, two sets of twin cylinders are faced off at a single setting. Considering the use of high-speed cutters, maintained in the best possible shape by competent men who do no other kind of work, the finished cylinders are accurately faced and interchangeability is accomplished. As an incident the work is done quickly, and, considering the accomplishment of the main task, the cost is not excessive.

The same figure shows how the cylinders are held in a fixture, the object of which is to eliminate the personal equation, preventing the workman from setting up the cylinders excepting in a way to afford the desired results. It is equally advantageous that the time of setting up the work is much reduced, considering the desire to have all cylinders exactly alike, in order that a repair will be easy to make if the occasion requires.

In the process the milling cutters rotate, due to the use of gears which engage a driving shaft, through a speed changing gearset. This takes power from an individual electrical motor which is bolted to a base cast on the frame of the planer. The platen on which the cylinders rest has a power feed, and it moves the cylinders up against the rotating cutters at the required speed.

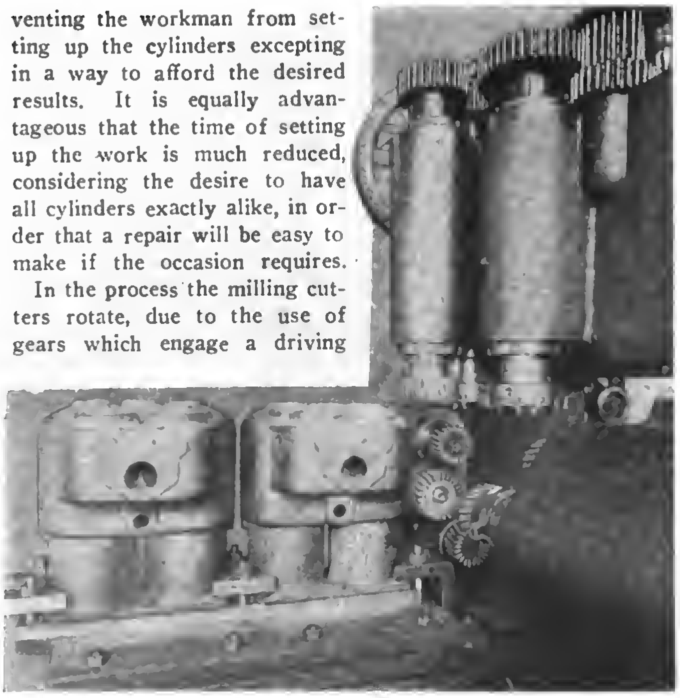

Fig. 5—Milling planers engaged in facing two sets of twin cylinders, and engaging nine milling cutters simultaneously

Big Turret Lathes Perform Intricate Tasks—Fig. 6 shows a drop forging which incorporates into the live rear axle for the finished car. The extending arms on this piece, to hold the brake fulcrum pin, render the part a difficult one to machine, which trouble is accentuated on account of the fine quality of the steel used. Chucked in a turret lathe of great strength and range, this task is reduced to practicability, and with six fixed tools on the turret the workman is enabled to do six separate operations at a setting, thus eliminating the error which would surely follow if the part had to be chucked six separate times. In this case the work rotates and the fixed cutters feed (with the turret) up against the rotating work, performing the operations to a nicety. As each operation is done the turret is swung back, a new tool is turreted into range, the feed is thrown in, and the next operation is performed. In this way there may be as many operations as there are fixed tools on the turret, and the work will be as accurate as the tool department keeps the cutters, which, in a shop of this character, is so close that interchangeability is a normal expectation

Fig. 6—Turret lathe working on a drop forging of intricate shape, as used in live rear axle work

Fig. 7—Turret lathe working on a nickel steel steering pivot held in a steady rest

Fig. 7 represents another important operation being performed on a turret lathe, in which a steering pivot is held on a face plate, centered in a steady rest and bored out by a boring tool. This is an extremely difficult operation, primarily, because the bore is not for a complete circle, then, due to the difficulty in holding the part, and finally in view of the tough and hard character of the nickel steel used.

Check Methods Must be Used.—When the parts are made, they go to the inspection department to be gauged, micrometered and inspected. If they come up to drawings and standards they pass on to the assembling departments. When they are assembled, considering the checking they receive in the testing department, it would seem as if they might then go directly into cars, especially in view of the customary road test every car receives.

Not so. If an adjustment is not rightly made noise will be the normal expectation, and if a bearing is set up too tight heat will soon be induced, even though oiling be profuse. To guard against all such matters the assembled rear axles, motors and transmissions are set up in testing machines, one of which is shown in Fig. 8. As will be observed, the axle is set upon pedestals so that the propeller shaft engages the shaft of an electric motor, from which power is obtained in excess of the power of the regular motor in the finished car. Fan blades are clamped to the live shaft of the axle and the motor is started. The speed of the electric motor may be increased at will, and may be even considerably higher than the highest possible speed the motor in the car will run at. If the bevel drive makes any noise at all it is examined and adjusted; if the noise cannot be removed the axle is dissembled and the reason ascertained. When the axle is made to run noiselessly at all speeds the test is continued until the bearings are run in. In this way much delay is saved, and the road testers of the finished cars are then able to make the customary 100 miles without having to tinker with the mechanism. A similar machine is used to test transmissions, and after they are adjusted to a noiseless performance they are kept under load until the bearings are run in and to assure that there is nothing wrong.

The idea has been to illustrate the manner in which special devices are made to serve the purpose of building cars, in which interchangeability is the main criterion, and with the understanding that quality must never be beyond the reach of the class of buyers who are catered to. The machines illustrated are but a few of the many in use in the Pierce plant.

AGRICULTURAL TRIALS AT BRANDON

Following the Winnipeg trials, so closely in fact as to almost form part of them, were the trials at Brandon, the same machines appearing at the latter place as competed at Winnipeg. As planned, the trials were to include brake, hauling, and plowing tests, but the tests dragged out so long that it was necessary to abandon the hauling test, which was last on the program. The plowing tests showed some very interesting results, the 25-horsepower Rumely steam tractor, for instance, hauling a 14-furrow 14-inch Deere plow a mile in 15 minutes. This was, however, done at the expense of fuel and water consumption, so this machine did not figure in the final results. There were, aside from the class awards, two championship prizes to the International Harvester Company, for gasoline engines, with the No. 3 20-horsepower machine; to the Avery Company, for steam engines, with No. 12, a 30-horsepower machine.

In column marked *, 80 points are the basis for marking gasoline engines—90 for steam. Possible points in gasoline engines, 155—in steam, 166.

IMPROVING CARBURETER FLEXIBILITY

By H. L. Towle

ALMOST any carbureter will give a reasonably good mixture through a limited range of action. Frequently, however, this range is found insufficient for a particular engine. If right for low speeds, it is wrong for high speeds, and vice versa. The owner, therefore, adjusts for the best results at his usual driving speeds, and he keeps within those speeds as much as he can. This limits the use of the machine.

Possibly the carbureter found thus deficient is giving the best results of which it is capable. If, however, it is of good design, there is hope of improving its action considerably by the simple device of providing it with the most suitable spring or springs, and occasonally by modifying the fixed air inlet or the spray orifice as well. The principles governing the action of helical springs are extremely simple, and by a few minutes devoted to their study any auxiliary air valve may be made to give the best results of which it is capable in that particular carbureter. The major portion of the following paragraphs will therefore be devoted to explaining the behavior of the springs.

The theory of carbureter action as regards the behavior of the gasoline jet under different air velocities is still only partially understood, and has been the subject of a great deal of more or less blind theorizing, based in many cases on wholly inadequate data. Into these theories it is not the purpose of the present article to digress, but rather to indicate to the non-technical owner how he can obtain the best results with the means at hand. That is, it partakes of the practical.

Non-Automatic Variety Causes Richness to Increase with Speed—A non-automatic spraying carbureter (i. e., a simple nozzle in an air tube) makes no mixture at all till the velocity of the air stream reaches a certain minimum. Beyond this point, the richness increases with the speed. Dilution from the auxiliary valve is therefore required only when the richness of the mixture exceeds the normal. At this point it should be remembered that, so far as the spray is concerned, there is no difference between a wide open throttle at slow engine speed (e. g., up hill) and reduced throttle with high engine speed. The spraying action is concerned only with the velocity of the air past the nozzle before the throttle is reached.

Almost every carbureter is provided with a needle valve controlling the spray orifice. With this provision it is very easy to determine whether or not the carbureter is doing as well as it should at either low or high speed. For example, suppose that we start with an adjustment known to be satisfactory for medium speeds. If the low speed performance is under suspicion, it is only necessary to increase the needle valve opening slightly to ascertain whether starting is thereby made easier and a walking pace more smoothly maintained. If overheating results, reducing the needle opening will probably cure it. Similarly slight changes in the needle opening, without changing any other adjustment, will determine whether or not the mixture is improved by less or more gasoline at high speed. The subsequent procedure will depend on whether (when the carbureter is correctly set for medium speeds) the mixture is:

A. Weak at low and rich at high speeds, or

B. Rich at low and weak at high speeds.

In the first case more, and in the second case less, air must be admitted at high speeds by the auxiliary valve. What springs will produce these results?

Some Spring Characteristics—It is a characteristic of all springs that their flexure is in direct proportion to the load imposed, up to the elastic limit of the spring. Thus, if the spring represented unloaded at *A*, Fig. 1, compresses 1-4-inch under a load of 2 ounces, it will compress another 1-4 inch under 2 ounces more, an inch under 8 ounces total load, and so on. This is the first, most important, and most easily remembered law.

It is apparent at a glance that if the spring in Fig. 1 deflects 1 inch under a certain load and has 8 turns, its deflection per turn will be 1-8 inch. If the spring were similar in every other respect, but had four turns instead of eight, that is, half as many, its total deflection for the same load would be only half as great. If it had sixteen turns its deflection would be twice as great, and so on. In other words, the more turns a spring has the less force is required to compress or extend it a certain total amount. The fewer it has, the greater is the force required for a given total deflection, simply because the needed deflection per turn is less or greater as the case may be. For this reason it is customary to reckon spring action in the amount of deflection per turn, and then supply turns enough to obtain the desired total deflection under the desired force. For example, suppose we want a spring similar to *A*, to deflect 5-16-inch under 4 ounces load. The deflection is 1-8-inch per turn under 8 ounces, or 1-16-inch under 4 ounces; consequently 5 turns will give the total deflection desired, namely, 5 times 1-16.

The second law of spring action is that the deflection per coil is proportional to the cube of the diameter of the coil measured to the center of the wire as in Fig. 2; that is to say, if we double the diameter of the coil using the same wire and same number of turns, the deflection per turn will be eight times as great. If we halve the diameter, the deflection will be one-eighth as great. This merely states the familiar fact that a large spring of a given wire is "soft," and a small spring stiff.

Third Law Deals with Diameter of Wire—The third law is that the deflection per turn is inversely proportional to the fourth diameter of the wire. If we double the diameter of the wire without changing the size of the coil we shall reduce the deflection per turn to one-sixteenth of its former amount.

These relations are expressed in the formula:

$$E = \frac{D^3 \times w}{d^4 \times K}$$

in which E is the deflection, D the diameter of the coil (see Fig. 2), w is the load, d the diameter of the wire, and K a constant depending on the units employed.

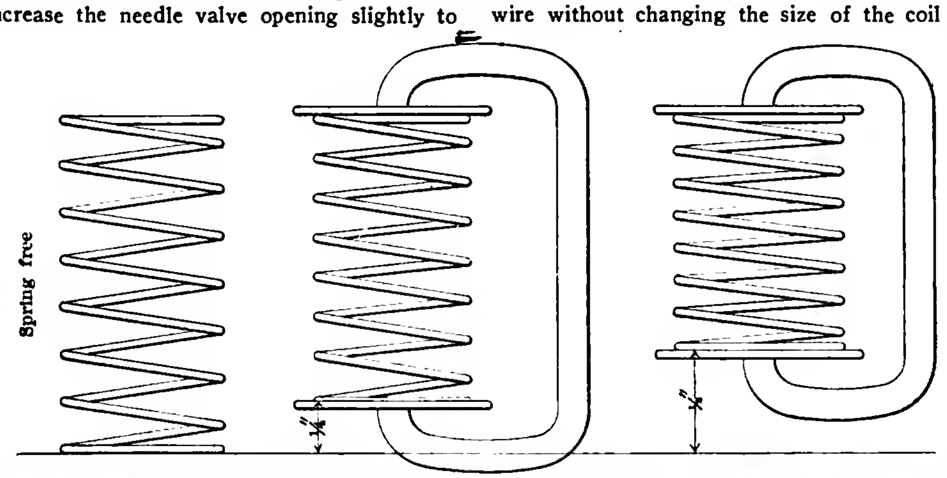

Fig. 1—Carbureter springs shown in three positions, first or A, free, second or B, partly closed, and third or C, compressed one-half inch

Now let us look at the carbureter. Instead of having the auxiliary air valve spring perfectly slack when the engine is at rest, so that the air valve opens on the slightest suction, we compress it so that a certain degree of suction is required to start the valve from its seat. Since the gas velocity is proportional to the suction, the valve will then open by equal amounts for equal increments of suction.

How is all this to be applied to the particular spring of the reader's own carbureter? Let us see. Suppose your carbureter is in the condition of *A*, noted above. You need a richer mixture for starting and a leaner mixture at high speeds. First examine your auxiliary valve to see whether there is room for wider opening, provided the adjustment of the stop is changed. If not, there is small hope that you can do much to improve it, though there is still a chance that you can help matters by enlarging both the primary air intake and the spraying orifice. It may be that you have a heater connection on the carbureter intake and that it strangles the air more than it should. Enlarge the heater, or disconnect it if the weather is not too cold. Then try running the car again. If the former intake was too small you will find that you can increase the needle opening somewhat on account of the reduced suction. This will give you both more air and more gasoline, and will help the performance at high speeds without impairing it at low speeds. Put the auxiliary air valve spring under tension so that it will not open till the motor gets up to speed, but be sure that it opens as much as needed at high speeds.

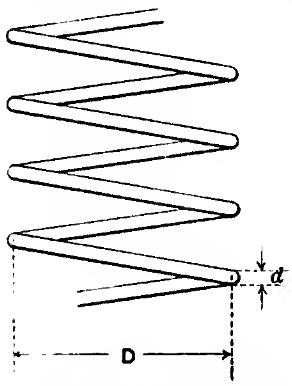

Fig. 2—Small coil spring with dimensions

To Improve Running at Low Speeds—Suppose, on the contrary, that your first examination shows a margin still available for further opening of the auxiliary air valve. To improve the running at low speeds, open the needle valve as much as required, and if necessary constrict slightly the primary air intake (if there is provision to do so). This will give a stronger suction or a freer flow of gasoline on starting. You may or may not find that simply slackening the air valve spring will give good results all the way from medium to high speeds. It may have the effect of letting the valve open too soon, giving a weak mixture at low speed. This indicates that the spring has too few turns, since when adjusted correctly for low speed its tension increases too rapidly with increased opening of the valve. Get a second spring with several more turns, winding it, if necessary, from brass wire or piano wire of the same thickness. Leave it with too many turns at first and shorten it one or two turns at a time. Stretching a spring is no substitute for added turns.

It may be that the spring, instead of being too short, was originally too long, and that over-richness at high speed has resulted, not from excessive spring tension, but from the necessity of substituting the stop for the spring, owing to the latter being too weak to hold the valve at high speed. Such a spring may permit the valve to open too early, causing weakness of the mixture at low speeds. Supposing that opening the needle valve has shown improved action at low speeds, restore the needle valve to its first setting and try tightening the air valve spring and slacken up on the stop. This is likely to improve matters up to a certain point. If, however, the valve still strikes the stop too early in the speed scale, cut one or two turns from the spring, stretch it or run the adjusting nut down, and try again. With the same tension on the valve when first opening, there will be an increased tension with maximum opening, and this increase may steady the valve sufficiently to permit the stop being run still further back.

Treatment of Too-Rich Mixture at Low Speeds—Now let us turn to the converse supposition "B," i.e., that the mixture is too rich at low speeds. This is invariably due to faulty selection of the auxiliary valve spring. The spring has too many coils, making it "soft," and to obtain sufficient tension to control the air valve at high speeds the spring is given an initial tension which carries beyond where it ought to be. It must be borne in mind that the permitted range of movement of the spring from shut to open of the air valve is very small. To correct the difficulty, simply cut off some of the turns, reducing the movement necessary to obtain the maximum tension.

The foregoing applies to all types of carbureters having spring controlled auxiliary air valves. In a few carbureters two such springs are used—a weak spring for low speeds and a stiffer spring for high speeds. The purpose of this is to correct an inherent tendency of the auxiliary valve to admit too little air at low speeds, and too much at high speeds. Its value will depend on the design of the particular carbureter. In some, all the air instead of a portion comes through the automatic air valve.

In case the spray orifice is not controlled by a needle valve, as in some carbureters having a fixed nozzle, the line of investigation must be altered somewhat. Unless these have a variable primary intake, all the adjusting must be carried out on the auxiliary air valve. If the primary intake is fixed, first adjust the auxiliary valve spring to give good results at medium speeds. Mark the spring adjustment and increase the tension to determine whether a richer mixture gives better results at low speed. If it does not, slacken the tension, confining yourself exclusively to low speeds during the test. Make a note of the setting which gives the best results, and try again in similar fashion for high speeds. You are now in a position to classify your case under *A* or *B* above, and to modify the spring setting intelligently.

Reducing Fixed Air Intake Reduces Suction—If the fixed air intake is variable, the rule to remember in adjusting it is that reducing this intake increases the suction in the mixing chamber, and thereby increases the richness at low speeds.

Of course, not all carbureters are equally good. A carbureter may be so proportioned that it is incapable of working well at low speeds when adjusted for ordinary speeds; less frequently it may show an incurable propensity for delivering an over rich mixture at high speeds. The former defect may be due simply to the carbureter being too large for the engine, which means that the air velocity through it is not sufficient at low speeds to atomize the gasoline properly; or it may arise from original bad design. For example, the "strangling passage" around the spray nozzle may be too large in proportion to the size of the auxiliary valve, or there may be no constriction whatever around the nozzle, as in certain types now obsolete. The latter defect—i. e., persistent over richness at high speed—generally indicates that the carbureter is too small for the engine, but it may arise from limitations of design, as a larger carbureter of the same model may not work well at low speed. In this latter case, the cause of the trouble lies probably in the auxiliary valve being too small even when adjusted for its maximum opening. The only thing to be done here is to insert a supplementary inlet valve in the intake piping between the carbureter and the engine.

Certain carbureters of what is known as the "puddle type" have no auxiliary air valves, but derive their automatic action purely from changes in the size of the puddle and from that fact that at low speeds suction is assisted by gravity in keeping the puddle filled. Carbureters of this type are very satisfactory in many cases, but they may be found to have a range not quite sufficient for the engine. This is easily determined by varying the needle valve setting as above indicated. It does not do to use a carbureter of this type too large for the engine; since then it will not work at low speeds. On the other hand, at high speeds the engine may not get sufficient mixture, and what it gets may be too rich if the adjustment is right for low speed. The remedy is to adjust for low speed and provide a small auxiliary valve between the mixing chamber and the throttle, with its spring under considerable initial tension, so that it opens only at high speeds. A large auxiliary air valve is unmanageable here because the slightest opening lets in considerable air, but with a small valve excellent results have been obtained.

KNOCKS AND NOISES THAT PERPLEX AMATEURS

By EDWARD S. KEOGH

ELUSIVE knocks and noises are the nightmare of the careful motorist and cause an otherwise pleasant journey to be an anxious, nerve-racking trip. It is a remarkable fact that every unusual knock or scrape is at once attributed to a defect in the engine; no doubt because the engine is the source of power and more in the mind of the driver than is any other part of the mechanism. Engine knocks also are to be feared, as a rule, more than knocks from other sources, as they tend to indicate loose bearings in shaft or piston, or loose cylinder bolts, anyone of which might result in serious injury to the motor.

But there are many noises which sometimes jar the ear of the driver and cause him to be anxious about his engine. These occur from other than engine defects, although from the rhythm of their occurrence one is positive that the engine is at fault. This, no doubt, is caused by the vibration of the engine jarring the loosened part and making the knock heard in accordance with its own vibrations.

Loose Oil Pipe Puzzled for a Long Time—The writer's car developed a knock at one time which seemed to come from the engine, but the cause was a loose oil pipe which ran from the dash, underneath the foot boards, to the transmission. This loose pipe rapped sharply on the bottom of the boards whenever the engine was speeded, giving all the symptoms of a very loose bearing until an examination revealed the actual condition. In another case a two-cylinder shaft-drive car developed a disheartening knock when on a long trip, which was laid to the connecting rods and the first garage met with was consulted for advice. The rods were examined by the garage man, who advised that they be tightened, which was done, although the driver hardly thought it was necessary. Soon after the trip was resumed, the knock again appeared, but the journey was continued to a certain garage where there was a mechanic in whom the driver had considerable faith as a troublefinder. This mechanic examined the connecting rods and said they were too tight and should be loosened and that the engine was all right. When the bearings were set to his satisfaction he proposed a short ride that he might hear the noise himself. The car was started and had not gone two hundred feet when he told the driver to stop and, getting down took up the foot boards and made an examination. It was found that the springs which held the forward end of one of the distance rods had broken and the rod was free to pound with the vibrations of the engine. An old exhaust valve spring was inserted and it has held better than the ones furnished by the maker.

Source of Trouble Usually Hard to Find—The same car developed an aggravating knock at one time which was extremely hard to find and which would show only when the engine was running free and on changing speed. It was found after many weeks that the crankshaft had too much end play and that the knock was caused by the flywheel hammering against the rear bearing. When the clutch was in, the flywheel was kept tight against the bearing and there was no knocking. This was more serious than at first appears, because the wear in the bearing caused the shaft to move forward, displacing the connecting rods from their proper line and causing undue strains on them and their bearings. In the same car an unusual noise or scraping occurred at the end of last season when the cold weather was approaching and made itself apparent usually at the beginning of a trip and disappeared gradually as the car warmed up. The cause of this was found to be that the cold weather had congealed the oil and grease in the gear case and that the gears cleared a path for themselves in the hard grease and then ran practically without lubrication until the heat generated softened the grease to a more fluid state.

The addition of some light oil cured the noise but did not improve the appearance of the garage floor under the car when it came in from a good run.

Now no noise or knock should be neglected, but the writer has found from experience that if you drive your car up a good stiff hill on high gear until the engine shows signs of laboring and no knock appears continuously with the explosions of the engine, you can be sure that your engine bearings and holding down bolts are tight and sound.

And if a slight knock does appear on such a severe test of the engine, there is no immediate necessity of the bearings being examined and tightened.

MOLECULAR WEIGHT OF DISTILLATES

The atomic weight of the elements entering into the fractions may be set down thus:

Hydrogen	1
Carbon	12
Oxygen	16

The molecular weight may be found as follows:

(a) butane, $C_4H_{10} = 4 \times 12 + 10 \times 1 = 58$;
(b) pentane, $C_5H_{12} = 5 \times 12 + 12 \times 1 = 72$;
(c) hexane, $C_6H_{14} = 6 \times 12 + 14 \times 1 = 86$;
(d) heptane, $C_7H_{16} = 7 \times 12 + 16 \times 1 = 100$;
(e) octane, $C_8H_{18} = 8 \times 12 + 18 \times 1 = 114$;
(f) nonane, $C_9H_{20} = 9 \times 12 + 20 \times 1 = 128$;
(g) decane, $C_{10}H_{22} = 10 \times 12 + 22 \times 1 = 142$.

In like manner the molecular weight of any of the compounds may be found, the rule for which may be stated as follows:

Multiply the atomic weight of each element by the number of atoms for each element and the sum of the respective products will be the molecular weight of the resultant compound.

In general practice it has been the custom to consider that gasoline was largely hexane, the molecular weight of which was taken in the further determinations. It is highly improbable that this method will serve, on the count that hexane is not now used to the same extent as formerly and the chances are that heptane and octane will have to be taken into account.

SPECIFIC HEAT OF HYDROCARBONS

In order to be able to estimate the losses in the exhaust of a motor it is necessary to know the specific heat of the elements and compounds determined by analysis of the exhaust, together with the range of temperatures, as well as the weight of the exhaust gases. The specific heat values are as follows:

ELEMENTS AND COMPOUNDS	SPECIFIC HEAT
Carbon	0.241
Carbon monoxide	0.2479
Oxygen	0.218
Hydrogen	0.244
Nitrogen (approximately)	0.240

Since over 80 per cent. of the whole weight of gas (mixture) will be nitrogen, it follows that much of the heat lost to the exhaust is taken away in the nitrogen. This fact, coupled with the absence of heat value in nitrogen, tends to the contention that nitrogen is an evil without a recompense. In the absence of nitrogen the fuel would be so quick-burning that the pistons would not be capable of receding rapidly enough to enable the functions to be performed, and it follows that some element has to be present the nature of which will serve to dampen the rate of flame propagation. Nitrogen is at hand in the right proportion and the cost of its provision is therefore nil, since, as exemplified above, it has no heat value.

PECULIAR POUNDING

Editor THE AUTOMOBILE:

[2,037]—I have a four-cylinder E-M-F "30" that has gone over four thousand miles without a particle of trouble that could be called trouble. I have nothing but praise for the car in regard to its keep-a-going and power qualities, but it has developed a knock that is very irritating and is something that I have been unable to fathom out. It seems to be something about the mixture as near as I can tell.

I will tell you what I have done and how the knock occurs: In starting up and getting under way everything runs smoothly and the motor seems to pull well, but when the car gets on a level road the knock commences. The knock synchronizes with the explosion in one of the four cylinders. Sometimes instead of knock there will be a pound, the sensation of which is one that you would imagine from a sudden and violent explosion in one of the cylinders. When there is a hill to climb, the car works like a charm, no knock or indications that she wants to knock, or in going down the hills when I use the motor to hold the car back. In brief, the knock only occurs on a level road or nearly level road, when the car gets up to the speed corresponding to the throttle opening. By first opening and then shutting the throttle down a little I can run the car without the knock. By putting more tension on the auxiliary air spring I can get more speed up before the knock begins, but if I continue to take up the tension, it consumes too much gasoline and soots everything up. I have had the cylinders off and cleaned all the carbon out of both cylinders and pistons. I examined all the bearings and can find nothing but moving fits, no looseness anywhere. If you can tell me where the trouble is and can suggest something to do to get this knock out I shall renew my subscription to "The Automobile" at once.

F. W. KAFER.

Lawrenceville, N. J.

There are a number of things which might, and, in fact, do cause pounding, but none of them seem to fit your case. The most obvious cause of pounding is that of a spark advanced too far. This, however, nearly always occurs upon hills, in deep sand or mud, or elsewhere, whenever the engine is laboring very hard. It could not be so in your case, as you distinctly state that manipulation of the throttle will cause it to stop and that it occurs only on smooth, level roads at rather slow speeds. In the case of too far advanced spark, manipulation of the spark would only make the pound worse than ever. So, too, if the spark was normally set too far advanced, it would pound more at high speeds than at slow, just the reverse of the actual case.

Preignition causes pounding, and is itself caused by overheated cylinder, piston or cylinder walls. Glowing points or deposits of carbon within the cylinder, as well as faulty or uncertain ignition also cause it. Leaks in the chamber are sometimes the cause of pounding, so too, are looseness of parts. Among the latter may be cited: connecting rod bearings, main bearings, loose flywheel, cracked flywheel, other lost motion. Beyond these things, the only other cause of pounding is that of some moving part which strikes as it rotates.

By listing these in a regular order and going through them one at a time, you will be able to run down the cause of the trouble, or incidental to your search, some contributory cause. Many of them may be eliminated at once, without wasting the time for a search, which will lighten your work. This is a kind of trouble of which we have never heard previous to this, and it doubtless is a combination of several things, some of which were not apparent in tbe searches which you made.

DIFFERENT KINDS OF PAINT

Editor THE AUTOMOBILE:

[2,038]—I have noticed in "The Automobile," issue of September 2, page 399, under the heading of "Information for the Man Who Drives," that you recommend for the brass and nickel parts of a car, a coat of man of war gray or oxidized bronze finish. What is this and where can it be obtained?

I. S. BOLES.

Shellsburg, Iowa.

Both of the finishes mentioned are but trade names for colors used in finishing cars, that is, they are nothing but paints. In buying a new car, these colors may be had for the asking, without extra charge, but it will be necessary to wait longer for the delivery of the car. If you have a car and wish to apply the color to it, buy it from any reputable paint maker, and it is applied the same as any other paint or color. If there is anything special about its application, the makers will advise you of that fact when the stuff is purchased. The use of paint like this is a very good thing, saving as it does many a long hour's work polishing up the readily-tarnished brass and nickeled parts.

BALL BEARING APPLICATION

Editor THE AUTOMOBILE:

[2,039]—Referring to Fig. 19 in the article on "Automobile Wheels and Rims" in your issue of Sept. 16, '09, we would like to ask, has this application of annular ball bearings been adopted with any degree of success, if so in what make of car? We believe such construction would be very near ideal with regard to friction and ease of application. If the bearing would stand up under the strains placed upon it due to peculiarity of this arrangement.

PETERSON BROTHERS.

Denver, Colo.

It is the impression that the arrangement spoken of is ideal, just as you have said, in that it does not represent an actual rear axle construction now in use. As a matter of fact, there are a number of firms now using the single row of balls, for the rear wheels, as well as a single ball for the front wheel knuckle bearing. From our present knowledge of ball bearings, we see no reason why this construction would not stand up, providing the bearing makers were consulted in the selection of the bearings.

You will note on looking at this figure again that it was used not for this purpose but to bring out another point, namely, the combination of the brake drum and inner flange, as well as the method of locking the bolts so that the nuts may be screwed up tighter or loosened at will, and that without dissembling the whole outfit.

WHOLE RANGE OF SUBJECTS

Editor THE AUTOMOBILE:

[2,040]—Will you please answer the following questions through your department, "Letters Interesting, Answered and Discussed"?

1. How shall I restore the coloring or recolor the inside of my pantasote top? The lining appears to be cloth. It was a purple but has faded. I want it black or very dark.

2. What is the best dressing for leather straps, etc., to keep them soft, pliable, and black?

3. Does properly proportioned alcohol and water have any injurious effect on the water system of a car? And is the cooling effect ample, as no doubt the alcohol boils at a lower temperature than water?

W. T. A.

St. Paul, Minn.

If the material of the inside of the top were cloth, as you say it appears to be, any ordinary dye would answer. In default of certain information relative to this, it would be advisable to communicate with the manufacturers, tbe Pantasote Co.

2. Without saying what is the best dressing, plain neatsfoot oil will keep the leather, or anything made of leatber, soft and pliable, if used freely. This may be obtained at any leather store. As for the color, it will have no effect on that, that is, if the color was black before using, it will remain black after use.

3. See another letter on this same subject elsewhere in this issue. A properly proportioned mixture is any old proportion, that is, there is no *proper* proportion. The only injurious effect is that the rubber hose at the joints is affected, but this is a very slow action and one that becomes lessened with the age of the mixture since the alcohol boils away gradually, leaving the mixture with a lessened proportion of alcohol, which constitutes the destructive part of the mixture. As the diagram of cooling effect shown in the other letter referred to above shows, a temperature of minus 30 may be obtained very easily. This mixture has to be watched very closely on account of the mixture boiling away as brought out above. The boiling point of alcohol at atmospheric pressure is 173 degrees Fahr., that of water at the same point being 212 deg. The mixture would have a boiling point somewhere between the two depending upon the proportions of each used.

To overcome this defect of the alcohol solution, many autoists use the alcohol-glycerine solution, with which the loss by boiling is reduced to a minimum. This is used by making first a solution of half and half alcohol and glycerine. The latter is then used just as any other liquid to make the final fluid. Glycerine itself lowers the boiling point very little, but the lessened quantity of the alcohol makes the boiling point for the whole solution much higher.

ANSWERED AND DISCUSSED

SHIPPING CAR TO 'FRISCO

Editor THE AUTOMOBILE:

[2,041]—Will you please give me some idea of the best way to ship a car from the East coast to the Far West coast, that is, from New York City to San Francisco? Is the all-rail route quicker or cheaper than the all-water route, or is the combined rail and water route the best? Is it better to ship in a special automobile car, or to crate and ship on a flat car? Will you also give me some idea of the time taken by a car to travel over this route, that is the shortest time upon which I may figure.

J. A. D. BYERS.

New York City.

While we cannot give you the best route, we can tell you something about the various routes and the conditions attaching to the shipment of a car over them, from which you may make your own deductions as to the best, or at least, the most advantageous. There are three routes by which you may ship: the all rail; the all water, and the combination route, part water and part rail.

The all-rail route presents the least number of difficulties, that is, you will only have to run your car into the New York freight depot and ship it, all other details being attended to by the railroad officials. By the all-water route, which is the longest, but to offset that, the cheapest per hundred pounds, it will be necessary to have the automobile crated, and then, the crate transported to the boat line dock. Then, you will have to have it uncrated at the western end after its arrival. By the rail-and-water combination route the same points offer, that is, it will be necessary to crate the automobile and parts.

For the all-rail route it is not necessary to crate, as the railroad company will furnish an end door or other special automobile car, and the railroad officials will block and otherwise fasten the machine in the car. In fact, shipping in this way, it would be foolish to crate as this only adds to the total weight, which is what you pay for. That is, crating only adds materially to your freight bill.

If you should crate and ship that way, it will be necessary to find out first of all, what total height the railroad will accept. Some of the roads have tunnels and low bridges, which limit the height of the crates which may be carried. Similarly, with the steamboat companies, most of them have a fixed maximum distance between decks, or in the hold, which would limit the height and probably the width of the crate.

As eighteen days is the ordinary time for the trip across by rail or rail and water, it is fairly safe to figure on the machine being there within three weeks. In figuring out the cheapest way to ship, it will be necessary to get an unbiased estimate of the weight of the crate, since you have to pay for this. The difference between the all-rail and the rail-and-water route is but $1.00 per hundred. If your crate weight times the lower rate was more than the saving per this route, the total to you would show a loss.

It is just barely possible that you may obtain from one of the numerous forwarding companies a more advantageous rate than the railroads offer. These companies ship many cars and place them so as to occupy less space than they would if placed by the railroad officials. In this way they are able to offer lesser rates. In a case of this sort, it is advisable to attend to, or at least inspect, the shipping of the car yourself to prevent careless fastening of the wheels in place. This might result in the car breaking loose in transit, with much consequent damage to it. The best way to handle the lamps and other small parts is to take them off and box securely.

OVERHEATING CYLINDER

Editor THE AUTOMOBILE:

[2,042]—I have a four-cylinder, four-cycle, forty horsepower car which has lately lost much power on hills. The car runs fine on the level, and even climbing grades. But after the throttle is opened about one-third of the way, the engine will knock, regardless of where the spark lever is placed. I have scraped the motor free from carbon, ground in the valves, and adjusted the carbureter in many different ways. Ignition (by magneto) is perfect as far as I can see. What is the trouble?

R. W. T.

Red Hook, N. Y.

Your pounding trouble may be due to overheating of the cylinders or piston, which, in turn, may result from poor design or from lack of ability in the water cooling system. If the interior of the cylinder overheats from any cause, pounding will result. The water is not always at fault, nor is this, as is thought by some, due to carbon deposits alone. A projecting fin, edge or knob of metal in the cylinder or on the piston will give as much knocking and be a great deal harder to find than the carbon. In fact, the latter is not hard to remove, while the former is.

Another little known cause of knocking, such as you describe, is a loss of compression through leaks. These latter may lie in the valve seats (not in your case though), in the valve caps, in the spark plugs openings and elsewhere. In looking up this trouble, investigate every opening into the cylinder. A similar though unsuspected source of trouble was described in a recent issue, under the caption, "Ingenuity in the Making of Repairs." You will find this on pages 353, 354 and 355 of the August 26 issue of THE AUTOMOBILE.

TO MAKE RUBBER CEMENT

Editor THE AUTOMOBILE:

[2,043]—Will you please tell me how to make a good rubber cement to use when vulcanizing tires?

A. L. C.

Webb City, Mo.

Rubber cement should always be similar to the mixed sheet of rubber upon which it is to be used. That is, it should contain the same percentage of sulphur. If care is not taken with this, strange and unexplainable results are attained in the vulcanizing process. Of course, you will not always be able to find out the proper amount of sulphur used in any one tire, but if the cement as made and used does not give good results, try adding more sulphur. If this should make matters worse, make some of the original cement over, using less sulphur. By keeping track of the various tires vulcanized, the composition of the cement used, and the results obtained, you will soon become very skillful in mixing and applying the proper composition.

Marine glue, so-called, is an excellent cement. This consists of one pound of caoutchouc to one gallon of coal tar naphtha and twenty pounds of shellac. Heat gently and pour on metal plates to solidify. When needed, melt. By using more naphtha, this is made thinner so as to stay liquid. The sulphur in this is in the caoutchouc, but if found insufficient in any one case, more sulphur may be added to the cement in the powdered form, when making it up, or if necessary, when remelting.

Another excellent cement is gutta-percha cement. The composition of this is two parts of gutta-percha to one part of common pitch. It is melted together, and well-stirred in the melting, the stirring being fully as important as the materials. When thoroughly melted and stirred, it is poured into cold water. This makes it into a hard brittle substance, which softens at a low temperature, and at 100 degrees is a thin fluid. Like the former recipe, this carries its own sulphur in the gutta-percha, but if more is necessary, it can be added as a powder. In this case, it is not advisable to add the sulphur during the remelting process, but it should be put in while making up a batch of the cement.

As a rule, as little cement should be used as is possible to make a good job. Moreover, all cement should be given plenty of time to dry. Rubber surfaces to be united should be thoroughly cleaned, either with naphtha or with a thin cement. When the latter is used, it is brushed over the surface very lightly, using a fine brush, and then the surfaces are heated gently. This helps the whole operation, because it both softens the rubber and evaporates the solvent, which is then unnecessary to complete the operation, having served its usefulness.

In addition to the various substances mentioned before for cements, it is very often necessary to have the cement dry very rapidly. In these cases, specific driers are added, and may usually be added to any cement at will, the quantity added being measured only by the required speed in drying. Then there are cases where certain degrees of tenacity are required. For these, other gums are added as rosin, mastic, gumlac, etc. These, however, should be used only when needed, and much discretion should be used in adding them to an already very satisfactory cement.

MILE-A-MINUTE FOR HIM

Editor THE AUTOMOBILE:

[2,044]—Will you please answer the following questions through "Letters Interesting, Answered and Discussed"?
1. Had I ought to have a complete knowledge of an automobile to become a racing driver?
2. Do automobile companies give inexperienced men a trial?

L. M. S.

Denison, Kansas.

Considering the unusual number of race meets which have been held during the present year, and the equally unusual number of fatalities attending the same, at least an average of one man killed per meet, it is surprising that anyone would have the temerity to want to take up racing as an occupation. However, to answer the above questions:

1. Yes, for this purpose you cannot have too complete and thorough a knowledge of not only the machine you expect to drive, but all others as well, and a very clear insight into the principles governing the action of all of the various parts. Not only should you be able to simply drive the car, but you should be able to assemble, dissemble, repair, machine, or do any other kind of work necessary to make any one of the pieces entering into the complete car, and to put it into place, or take it out under any and all conditions. That is, you should be an expert on engines, transmissions, clutches, and other components, as well as on driving. As far as simple driving is concerned, a man of ordinary intelligence can learn to drive in the course of a single day, granting only a car to drive, and someone to show him how. Beyond that comes the superlative skill to permit a man to get more speed out of any given car than any one else can. More even than personal skill, a cool head and steady nerves are required. Without the requisite nerve and coolness, necessary to drive, say at the rate of a mile a minute carrying your gasoline tank in your lap, any amount of skill in handling a machine is of no possible use. More than this, accurate judgment is required since the tight places in which a racing driver is sometimes placed require not leisurely consideration, but instant and immediate decision as to what is best to do, and equally fast work in doing it. An ideal way to prepare yourself for this work would be to go into some automobile factory and work at least six months in each and every department there, closing with about a year of outside testing work. In that length of time (it would doubtless run into three or four years), you would have proved that you possessed the requisite skill, judgment, nerve, and cool head. At that time you would find little trouble in obtaining a situation as a racing driver, since the supply is always less than the demand.

2. Nearly every firm finds it necessary to hire inexperienced men, who are not hired for the purpose of making racing drivers of them, but to learn the machinist's trade. The way for you to start in will be as an apprentice, then when you have had a little automobile shop experience, change to a position in which you would learn, for instance, to assemble engines, later one in which you would test them, etc. If money is no object, you may obtain a position in nearly any automobile factory in the country.

PROPER ALCOHOL SOLUTION

Editor THE AUTOMOBILE:

[2,045]—Will you please answer the following through "Letters?" What proportion of denatured alcohol and water is proper for an anti-freezing solution? Is there anything in this same line which you consider better than alcohol, and if so, what is it?

TRUMAN B. PEIRCE.

Providence, R. I.

As a matter of fact there is no proper proportion, as any one of a number of proportions will give satisfactory results. There is this to be said, however, that the weakest solution which will stand the climate in which you are located will give the most satisfactory results. The reason for this is that the alcohol evaporates out from the solution, and the stronger the solution, the more there is to evaporate, the easier it evaporates, and the greater the influence of this evaporation upon the solution left.

Accompanying this is given a diagram of the freezing points of various solutions of denatured alcohol in water. From this diagram select the lowest temperature which you are sure to meet and that will give you the strength of mixture to use. In making this selection, remember the advice given above. Since zero is seldom met with, you might try a 38 per cent. solution which will not freeze until that temperature, 0 deg., is exceeded.

Unless you are particularly desirous of using denatured alcohol, you will note from the diagram that wood alcohol gives a much lower temperature, the percentage mentioned above yielding about minus 22 degrees with wood alcohol. No particular one of these solutions is recommended and all of them have their drawbacks. So, the best way to do is to try one and if this does not suit you for any reason, try another. In this connection, see the letter of W. T. A. [2,040] elsewhere in this issue, as well as J. A. Rene [2,029] in the Sept. 30 issue, and that of E. W. J. in the Sept. 16 issue. Both of the two latter have tried various cooling solutions, and this winter are about to try the use of a light oil.

Do not think that because nothing has been said about other cooling fluids than the two kinds of alcohol and oil, that none of the others is as good. This is not the case; these were dwelt upon because you asked about the one, and the other was the subject of the most recent letter on this same subject. Calcium chloride, the curve of which was presented very recently, is very satisfactory to some, as is just plain salt to others. This latter, however, yields but zero degrees, so is not available where temperatures lower than that are common. Then the salts, which are not so well known as potassium carbonate, alone and in combination, are much used.

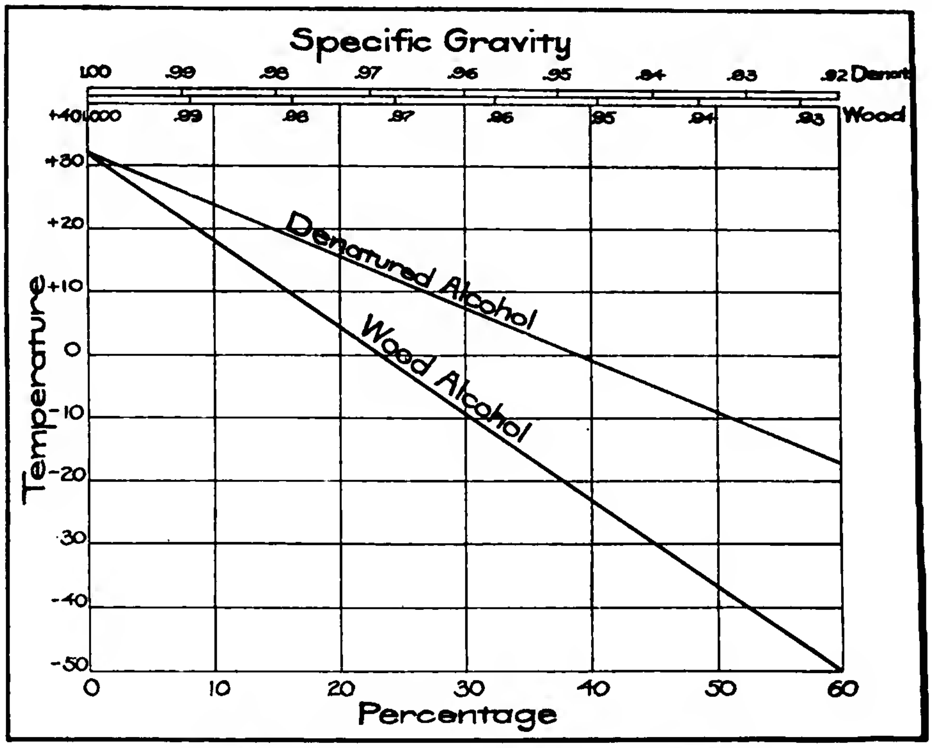

Diagram Showing Freezing Temperature of Alcohol Solutions

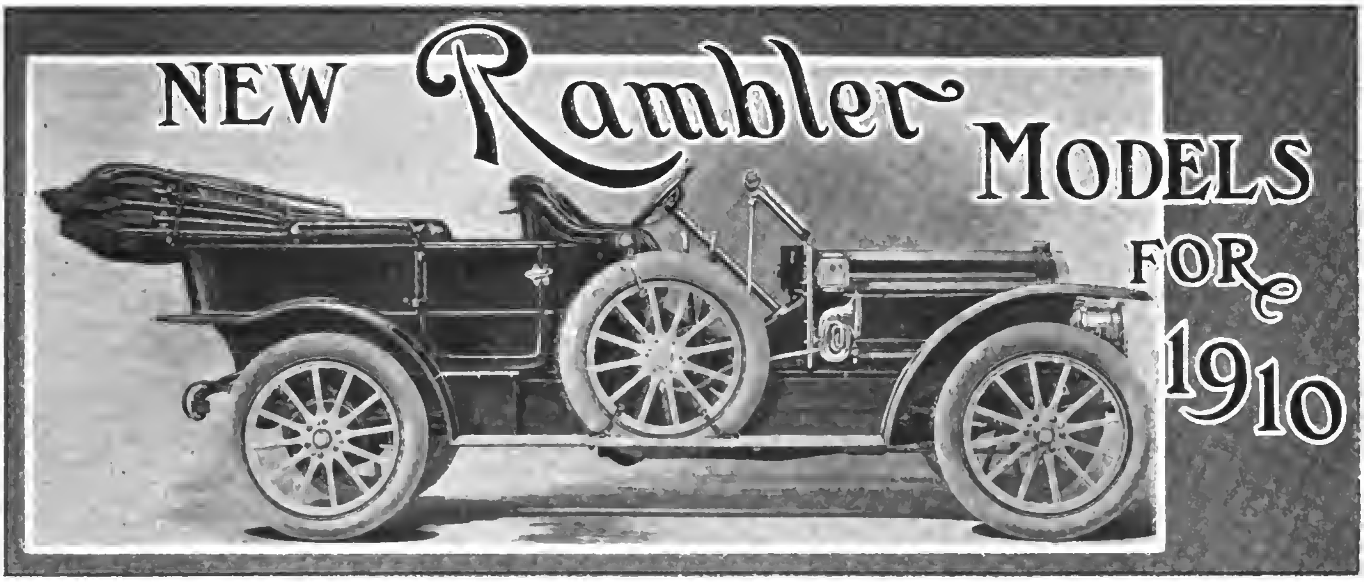
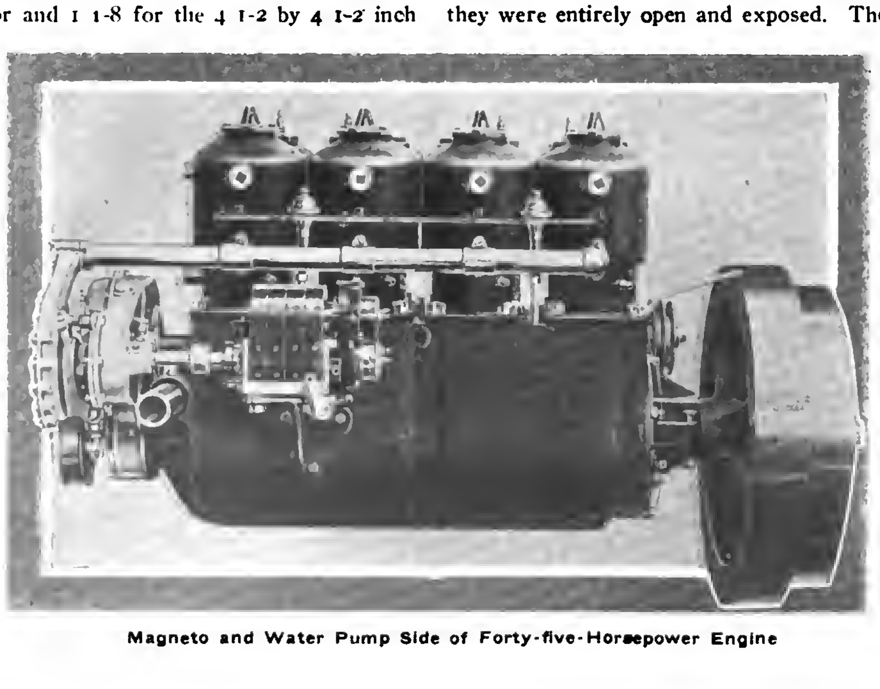


Model "Fifty-five" Is the Name of the Newest Addition to the Rambler Family

WITH the record of another year's successful culmination, and the satisfaction accruing thereto, many a manufacturer is now laying aside the season of 1909 and beginning to attack the problems of another year, that of 1910. This is particularly the case with Thomas B. Jeffery & Company, the features peculiar to whose Rambler car have attracted many. Among these may be mentioned the offset crankshaft, large diameter wheels, straight line drive, spare wheel, and engine accessibility. All of these features will be retained with such amplifications as another year of hard use has dictated. The accessibility idea, in particular, will be carried further, all adjustments having been made more get-at-able than before. This is an improvement which savors of common sense, since an inaccessible adjustment is about as valuable as no adjustment at all. All told there will be five models, but the number of chassis is limited to three, while the engines to be built total but two, and the transmissions, the same.

What the Engines Show—All of the engines are of the four-cylinder type. The cylinder castings are individual, with the valves located on the right, a la Renault. This construction makes the cylinder very simple, and correspondingly safer to use. The crankshaft is offset to the amount of one-fourth of the stroke in each case. This would be 1 3-8 inch for the larger or 5 by 5 1-2 inch motor and 1 1-8 for the 4 1-2 by 4 1-2 inch engine. When first brought out, this was a feature of doubtful utility and one that met with much skepticism. This fact makes its present universal acceptance of more than ordinary value. In fact, the question for argument to-day is not of the advisability of offsetting, which is granted, but, rather, the most advantageous offset. The Rambler manufacturers selected one-fourth as the proper proportion of the stroke after much expensive experimentation. After several years' use, no reason for changing it has yet appeared. The cylinders are of a close-grained gray iron, while the crankcase is also of cast iron. This latter is now in line with the most modern practice, which is taking account of the unreliability of lighter metals under severe stresses. The case is of the barrel type, that is, it is cast in one piece, with open ends. The crankshaft is put in through the ends, which are then closed by means of circular plates. These latter carry the end bearings also. Speaking of bearings, the individual cylinder construction allows of the use of a bearing on each side of each cylinder or five total for a four-cylinder engine. The many and various advantages of numerous bearings need not be repeated—they are too well known. The shortest, simplest and easiest way to explain it is to say that the result is longer life for the crankshaft and better service during its life.

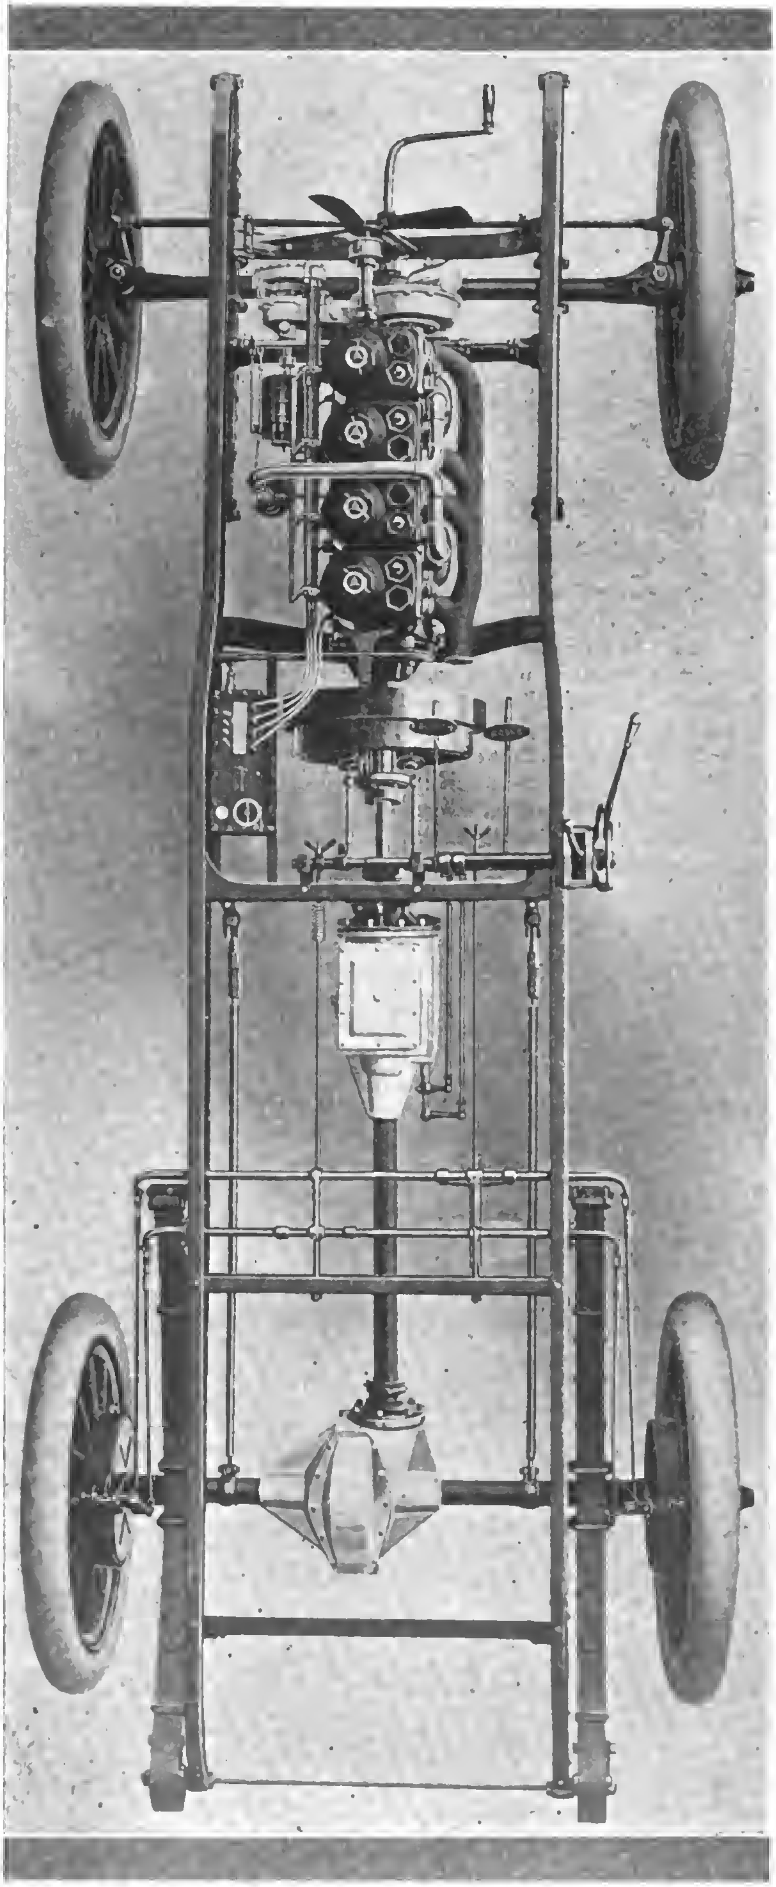
The barrel crankcase would result in the bearings being very difficult to adjust were it not for the fact that a special design of adjustment is used, and for the additional fact that the valve side of the case is made with a very large hand-hole plate. This measures 8 inches in width by 23 inches long, so that with it removed the whole interior of the case is as open and accessible as if there was no such thing as a one-piece case. Main bearings, connecting rod bearings, camshaft bearings and all parts may be inspected readily, and work done upon them as easily as if they were entirely open and exposed. The wedge method of adjustment of the main bearings is new, but possesses much of sterling worth, which will lead to extensive duplication. The upper part of the bearing housing is milled to a taper surface. This rests against a taper block which presses on the crankcase. To adjust, one tightens up the two bolts which move the block, the amount of motion of the nuts determining the movement of the bearing. The taper being slight, this can be regulated very accurately, even to thousandths of an inch.



Magneto and Water Pump Side of Forty-five-Horsepower Engine

Some Other Engine Features—In the 1910 model the pump has been moved to a position forward of the cam gear case. This change is to provide for a more accessible magneto location. It is now located on an extension of the pump shaft just back of the cam gears. It can be very easily reached for both inspection and adjustment. The magneto is placed on a shelf which is attached to the plain side of the crankcase by means of three studs. The magneto itself is driven through a slip joint, so that it may be lifted out of place for inspection, adjustment, or repairs. This may be effected as soon as it is released, which is done by taking out the holding bolts, four in number. The top or delivery end of the pump is carried over to the center and up, so that from the delivery end to the cylinder water inlets is a straight line, as soon as the right-angled turn has been passed. This makes the water-inlet piping very simple, consisting as it does of a single straight pipe, with the attaching cylinder flanges as the only projections.

Three-point suspension is effected for the engine by the use of a front supporting tube, which passes through the upper portion of the crankcase and forms the two forward points. The rear point is formed by the I-section cross member, which drops down from the level of the main frame so as to pass below the rear end of the case. The upper surface of this is milled out at the center, and the lower portion of the rear of the case has a circular pad at its lowest point, which is machined to match the finished surface of the support. The whole forms a sort of cradle upon which the rear end of the case rests. The front support, or tube, is carried by another I-section drop-forging, attached to the main frame at the sides. This, too, drops down so as to pass under the case at the front end. While actually unnecessary this makes an excellent stiffener for the forward end of the frame, so that its use is a good feature. The tube is not used as a support alone, the spark and throttle levers being pivoted upon it. This saves weight, as otherwise brackets would have to be used. These would require attachment to the frames, and the total weight of brackets, bolts, etc., would be considerable—enough at least to be worth saving.



Chassis View Showing Construction and Placing of Parts

In the interest of convenience and simplification, the compression cocks have been located in the side of the compression chamber, on the back or left side of the cylinders. In this position, a single bar connects the operating levers of all of them. This bar is prolonged, and may project either through the dashboard or forward through the radiator. In the former position, it is handy for testing the compression while running the car, and without leaving the seat. In the latter location, it is handy when starting, in that the slightest movement of the bar lessens the compression in all four cylinders, thus making starting much easier, and consequently less dangerous.

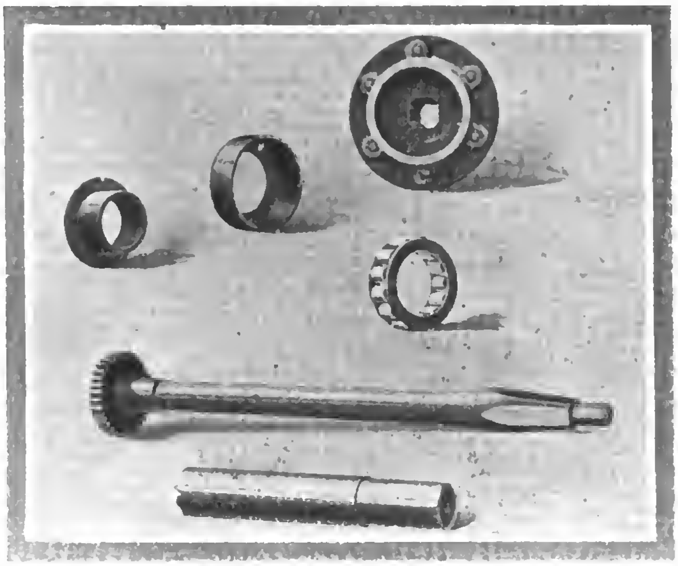
All of the accessories are driven from the engine either at the forward end or from the rear. The fan, for instance, is hung from a bracket attached to the front cylinder. In this position it is driven from the crankshaft extension by means of a large diameter pulley and through the medium of a wide flat belt. The fan is of large diameter and has four blades. The mechanical oiler is placed at the left side of the frame, just opposite the clutch and operating mechanism. This is the point where the frame widens out, and there is a considerable space there. To utilize this otherwise waste space, a short angle in combination with the main frame forms a small sub-frame upon which the oiler is fixed. This brings the forward end, carrying the driving pulley, opposite the end of the camshaft, from which the drive is by belt. The driving pulley is located on the rear extension of the camshaft, and drives across the car in a straight line to the oiler. The leads proceed to the various points to be lubricated, with the single exception of a sight feed located on the dashboard, in front of the driver.

A new feature which will be found on the 1910 models only is the provision against the usual dropping of oil from the crankcase ends. This consists of a combined shield and oil gutter attached to the crankcase at the rear of the flywheel and main bearing, which returns all surplus oil that may work through this bearing back to the crankcase. This eliminates the possibility of its dropping on to the flywheel and being thrown on to the other parts of the mechanism.

Wedge Adjustment of the Engine Bearings

Big Changes In the Clutch—In models Fifty-five and Fifty-four chassis the clutch has been changed from the cone type to internal expanding. This eliminates end thrust on the crankshaft and its design is such that it exerts the greatest pressure when fully engaged. With the average clutch, the spring is expanded when the clutch is engaged so that it then exerts the least instead of the maximum pressure. This clutch has been very thoroughly tested on a number of different cars, and has been found to be ideal in operation. It engages very gradually, holds positively, and disengages instantly. In model Fifty-three, the lowest priced car of the line, the clutch remains unchanged, that is, it is of the cone type, with readily accessible external adjustment of the coil spring.

Meritorious Features of the Transmissions—All of the gear boxes afford the same number of speeds, three forward and reverse. They are all of the selective type of sliding gear, also. The cases are of aluminum, closed at the front end by a cast-iron circular plate. These cases are of the barrel type similar to the engine cases, and large hand-hole plates located on the top correspond to the plates on the side of the engine case. This forward plate carries the stresses from the drive and is connected to the bearing at that point. This bearing is located on a cross-member placed there for the particular purpose of supporting the combined joint and drive bearing. The only change in the transmission is at the roller bearing which carries the forward end of the main drive shaft. This is a hinged bearing with a dowel fastening, retained in a steel case and provided with adequate means to compensate for all end thrust.

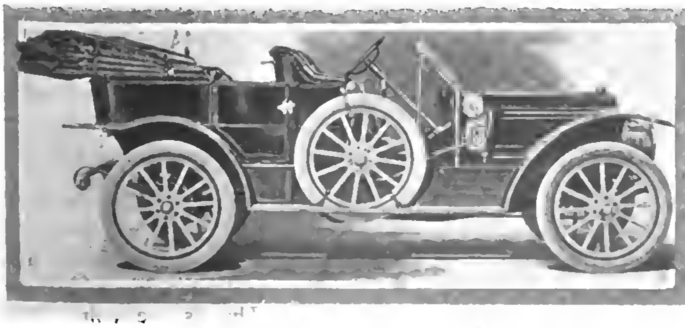


New Rear Axle with Roller Bearing and Other Parts

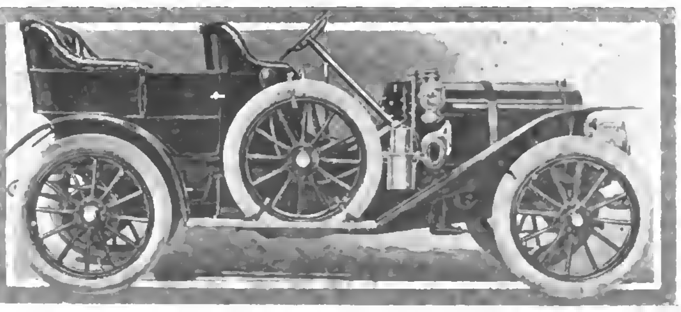
The rear bearing of the gear case is carried backward for quite a distance, while the forward end of the differential case is similarly carried forward toward the transmission. The two projecting ends carry the tube which houses the driving shaft, and the additional length renders the construction firmer.

Axle Changes Slight Refinements Only—The rear axle continues of the semi-floating type but the drive shafts are larger and a new method is used for securing the wheels. On the Rambler drive shafts, the differential gear is upset on the end of the shaft, making the drive gear and axle integral. Now, the wheel end of the shaft is also upset. This enlarged end is squared and tapered for the forged wheel hub. This method of upsetting or enlarging the shaft before squaring it makes it strongest where otherwise it would be weak.

To list the five models as concisely as possible, these are: Model Fifty-five with seven-passenger touring body and with seven-passenger limousine; Model Fifty-four in five-passenger touring style or four-passenger close-coupled body; and Model Fifty-three, which is only made as a five-passenger tourer. Fifty-five has a 45-horsepower engine, 36-inch wheels, 123-inch wheelbase and 4 1-2-inch tires for the touring car. The same chassis fitted with 5-inch tires serves for the limousine. Model Fifty-four also has a 45-horsepower engine, but the wheelbase is shorter, 117 inches. The wheels are 36 inches in diameter, and the tires, 4-inch. On the lowest priced car, Model Fifty-three, which is almost a duplicate of last year's model Forty-four, is used a 34-horsepower motor, 108-inch wheelbase, 36 wheels, and 3 1-2-inch tires, with 4-inch fitted as an extra at $20.



As Model "Fifty-five" Appears with Top and Windshield



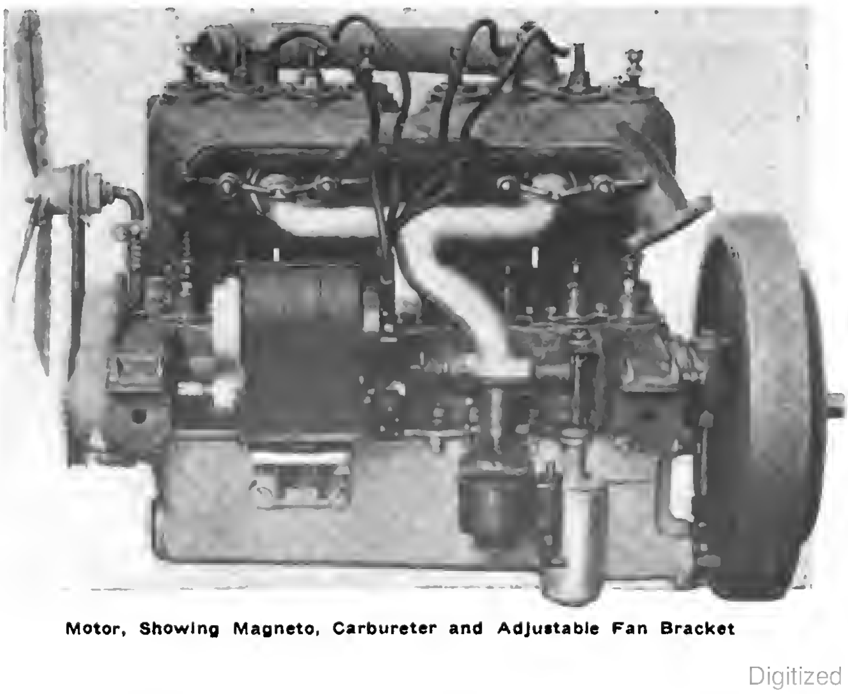
Rambler Model "Fifty-three" Five-Passenger Touring Car

STABILITY, when it is realized, is a readily recognized quality, and in the Regal 30 car, owing to the satisfactory performance of the 1909 model, only minor deviations were considered desirable, it being the idea to take advantage of experience gained in turning out 2,000 of these cars during the past year, and bring the model up to date in point of general external appearance as well as mechanical details.

External appearance of the latest model will best be gleaned by scrutinizing the halftone of a photograph of the car, and, in the doing, observe that the lines are in good taste and the side entrance is wide, due to the lengthened wheelbase, which was increased by two inches, making the same 107 inches. In order to improve further the appearance of the car, the dash is curved, and highly finished Mexican mahogany is used for the purpose.

It is not wholly the roomy body that makes the new car so pleasing, for in addition the spring suspension is refined to a high state of perfection, and full scroll springs in the rear take care of all longitudinal tendencies as well as the vertical bounce induced by road inequalities. Then, the wheels are big in diameter, using 32 x 3 1-2 tires front and rear, which selection also affords the advantage of reducing the spare tires usually carried to a single casing. This feature is well worth while.

The body is of metal, highly finished, due to twenty separate coats of "rough stuff" and finish, of a quality designed to afford permanence. The framing of the metal body is designed for lightness without sacrificing strength, and the metal work is so placed as to hold its shape, offering the additional advantage of not being susceptible to dampness, checking, etc. The body is stoutly ironed, all the fittings are good and particularly neat in appearance, and the upholstery is leather of selected grades, neatly tufted, and the cushions are in full accord with the usual best requirements.



Motor, Showing Magneto, Carbureter and Adjustable Fan Bracket

Mechanical Features of the Regal—Since the general view offers the advantage of depicting the exact appearance of the car, it is believed that all ends will be served if the design of the car as a whole and working drawings of some of the most important assemblages are presented at this time, with a view of discussing the details. The motor is of the four-cylinder, water-cooled type, with L cylinders, and the valves are located on one side. Cooling is by thermo-syphon; hence, in the list of accessories, there is no water pump, and the radiator, located on the center line of the front axle, is especially designed to prevent steaming, whether the car is running at any of its speeds or standing at the curb. The reason why the radiator does not steam will be understood by referring to the features of it. The force of any entrained steam passes into a pocket and there divides, part of the water passing downward, and the balance going up; but any entrained steam, instead of oozing out through the overflow, has its heat abstracted from it by the water it has to mingle with, and is therefore liquefied.

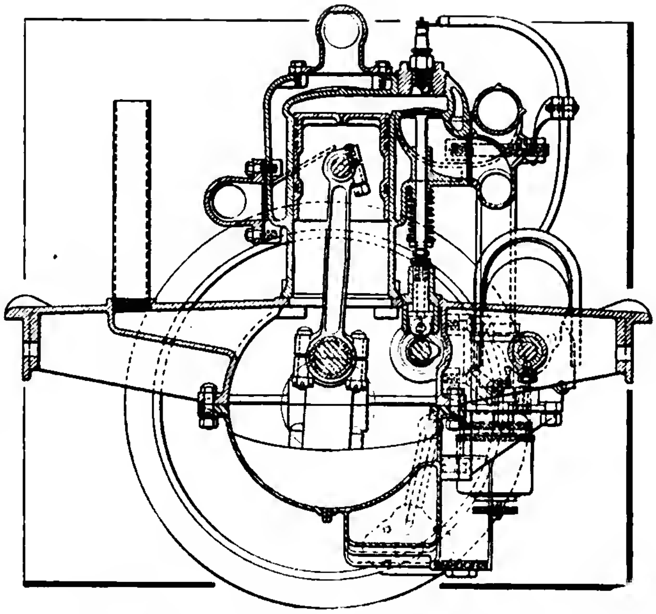
Exposing Details of the Motor—To understand the refinements in design, it will be better to examine a cross-section of the motor, cutting through the center line of one of the cylinders. The cylinder walls are of even thickness, with a generally symmetrical design and valves of adequate area to assure maximum power. The passageways are of even contour, free from obstructions, and designed to abort back pressure on the exhaust side, as well as to prevent an excess induction depression anywhere.

Compression space is calculated to afford the greatest amount of power, favorably influence conditions of ignition, and enable the motor to perform under severe conditions without laboring. The crankcase is of circular section and great strength. It is vented by means of a large "breather" tube, so placed and baffled that oil will not splash up and out, or silt drift in.

The pistons, which, like the cylinders, are of a fine grade of gray cylinder iron, are light enough to limit inertia troubles at high speeds and strong enough to sustain against maximum pressures. Four rings are provided, so made and fitted that compression leakage is prevented. This condition is permanent, owing to liberal bearing surfaces, machining close to limits, and low pressures, both as respects surface and in the fiber of the material. The piston pin is of heat-treated alloy steel, hardened and ground to exact size, thus assuring stability of fit, absence of lost motion, and kinetic qualities to resist the severe shocks of ordinary use.

Crankshaft and Connecting Rod—The connecting rod is of the I-section, designed for strength and light weight, has a take-up bearing at the piston pin, where it is suitably bushed and provided with a clamping bolt of ample proportions. At the crankshaft end, the connecting rod is very carefully designed to eliminate every fraction of excess weight. Brasses are lined with a fine grade of white bearing metal, and, in fitting, all bearings are blued and scraped by men of skill in this process, to assure perfect bearing and an even pressure at all points. The crankshaft is drop forged from a special grade of crankshaft steel, is heat-treated to render material highly kinetic and to improve the qualities of the bearing surfaces. The crankshaft sections at the different points are carefully designed to assure a low limit of the extreme fiber strain, and bearing surfaces are on a basis of safety.

Lubrication Is Positive—While the positive system of lubrication is used, it will be worth while to note that in this motor the oil level is maintained by means of an overflow system to a "sump," which shows in the bottom half of the crankcase, to the right. When the oil enters this space, it is lifted by a gear pump of excess capacity, passes up through passageways in the case, and is shot out against the bearings to be lubricated, which bearings are suitably provided with channels for the purpose. The result is, the lubrication is profuse. Since it is important to know how much lubricating oil there may be in a system, the motor is provided with a tell-tale so located that it may be readily seen, and is actuated by means of a float in the oil well, but it is so arranged that the glass will not coat over and hide the readings. The float is of cork, and operates much the same as the float of a carbureter. This is fixed at the lower end of a vertical rod, upon the upper extremity of which is attached the indicating disc. The latter thus moves up and down, with the float which marks the oil level, and registers the same on the gauge glass, the same being visible to the driver

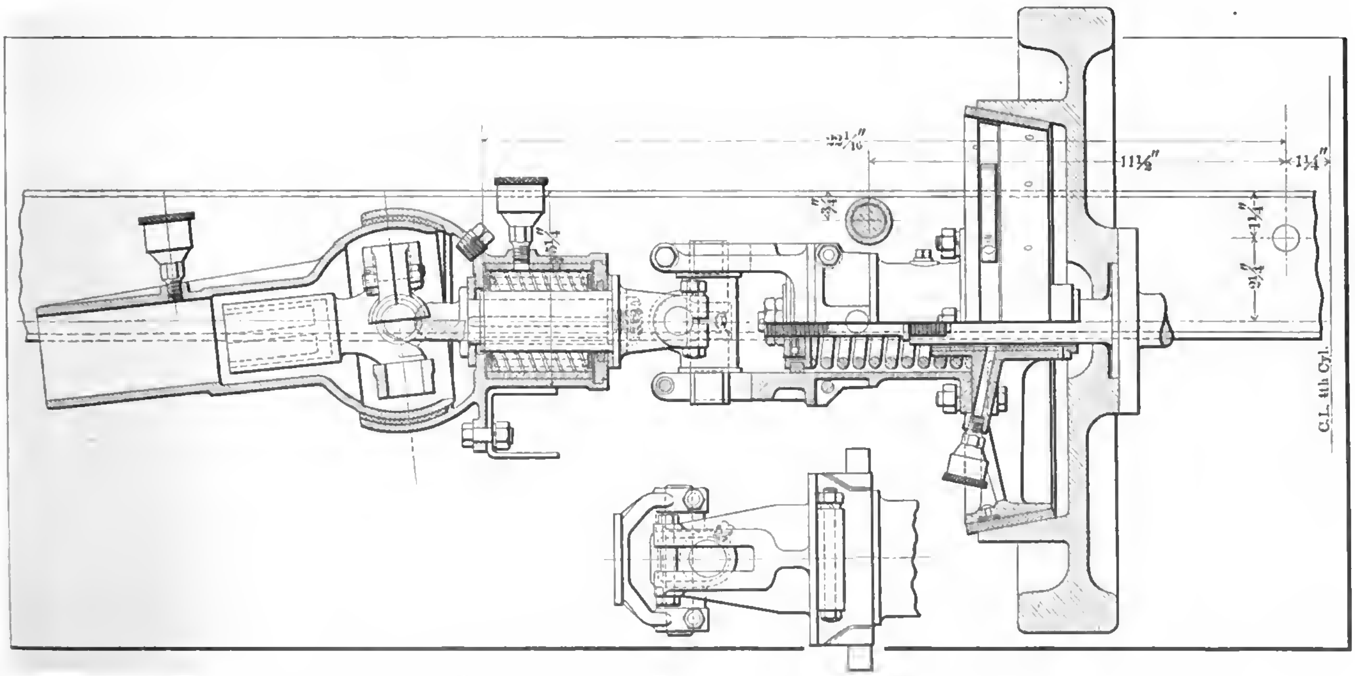


Cross Section Through Engine Displays Large Valves

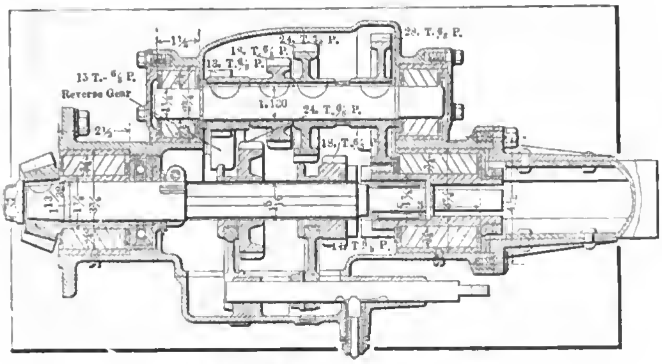
from the exterior. The fan bracket has also been changed, and is attached to the front cylinder with proper adjusting means.

Among the remaining important points to be noticed in the motor, attention will be diverted to the means for adjusting the lift of the valves, and since an integral camshaft enables the use of proper-sized rollers on the ends of the lifts, the actual clearance for the tappets is a minimum, and tappet-knocking is eliminated. The valves are of adequate area to do the required work and it was not necessary to make the lift pronounced, with the result that noise tendencies and hammer blows are not present. With ready means for adjustment, which consists of a nut and lock at the end of the lift, it is an easy matter to retime the motor.

Three-Speed Selective Transmission—Referring to the cut of the transmission—which lies in a direct line to the rear of the motor—this is suspended on the propeller-shaft tube, and the weight is borne by the chassis lateral stiffener and rear axle. The housing for the shaft between the clutch and the transmission is a large and stout tube, while the joint is not only capable of supporting thrust and tension, but it is free to respond to all road inequalities. The transmission housing is



Assembled Clutch with Universal Joint, Central Bearing, and the Relating Parts—A Very Neat Assembly



Regal Three-Speed Transmission, Showing Compactness

relatively small, of light weight, shaped for strength, and holds the gear set centered in Hyatt nickel-steel roller bearings of liberal proportions. The gear shafts, both direct and "lay," are short, of liberal sectional area, hence rigid in the extreme, rendered more so by the use of a selected grade of nickel steel, the gears, as well, being of this material.

Elsewhere in this article, a cut shows the leather-faced cone clutch of suitable diameter. The leather is pressed out by flat springs disposed around the periphery. The clutch spring is strong, and a ball-bearing takes the thrust. Just back of the spring, a joint engages a roller bearing, which, in turn, rests on a cross-member of the chassis frame, so that all stresses are transmitted to the frame just in front of the propeller-shaft tube, close to the axis of motion of the universal joint. All rear axle torsional moments are resisted by the large tube, relative motion is cared for, and the spacing between the axle and the joint is maintained in the same way.

Steering Mechanism Makes for Sturdiness—The steering gear, when cut through the longitudinal center, discloses a helical gear mounted on liberal bearings, with provision for taking thrust on both directions and means for taking up any lost motion which may be generated. The housing of the gear is grease-tight, of suitable proportions, and by means of a webbed foot, is bolted to an arm of the motor, thus affording a stable anchorage, which is a guarantee against lost motion.

Ball and socket joints of large diameter (one of which shows in the figure) are provided at every point, and the levers and linkages are made considerably stronger in all respects than would seem to be required. The steering wheel is of a most substantial design, holding the wood of the wheel in rigid relation, and the levers and rods for the spark and throttle control are enclosed within the steering post, connecting with the spark and throttle levers on top of the steering wheel. The "rake" of the steering column is 45 degrees in touring cars and 54 degrees in the runabout type.

With the power plant of the size used, so located that the moments are in closely-coupled relations, considering a low center of gravity, the adequacy of the spring suspension, and other design features to match, it is claimed by the Regal Motor Car Company of Detroit, Mich., makers of this car, that maintenance will be at a minimum, although, since the power for weight ratio is favorable, the speed of the car is above average expectations. Naturally, the reflections as to the future of this model are on a reasonably certain basis, due to the experience gained from 2,000 cars of substantially this design, which have uneventfully weathered over a year's service.

Besides the customary equipment—as lamps, generator, etc.—each power plant includes a Remy magneto, making a dual ignition system, in view of the auxiliary spark coil, battery, etc., furnished with every car at the price, which is $1,250.

BEVEL TURNING LATHE SIMPLIFIES SHOP WORK

BEVEL GEARS, which in automobile shop work are customarily turned on engine and turret lathes, can be more satisfactorily handled on a special machine recently brought out for this purpose by the Bridgeford Machine Tool Works, of Rochester, N. Y. This machine has been especially designed to turn simultaneously the face, front and back angles of bevel gears and pinions up to 18 inches in diameter. It will also handle advantageously the first operation of boring and facing the back.

The illustrations give a good idea of the general appearance of the machine. Drive is through a constant-speed pulley, 15 inches in diameter for a 6-inch belt, running at 440 revolutions per minute; twelve spindle speeds are provided, ranging from 5.8 to 214 revolutions. Three cutting tools may be used up to the limit. The carriage has a travel of 13 inches, and is provided with two cross-slides carrying angle-turning rests, that on the right having a turret tool holder. The feed box gives ten ratios of feed, ranging from .005 to .190 inch per revolution of the spindle.

For the first operation the blank is chucked in a universal chuck and bored with a tool in the left-hand rest, while the facing is done by tools held in the turret of the right-hand rest. For the second operation the blank is chucked either on a special hub or an arbor in the taper spindle hole. The left-hand turning rest carries a roughing and finishing tool for the face angle and the turret of the right-hand rest a set of roughing and finishing tools for the front and back angles.

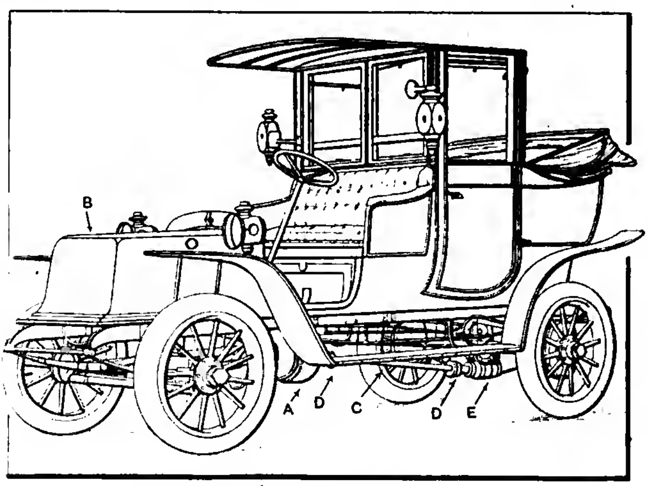
Babcock Electric Model 11 for 1910, Depicting a Town Car with the Landau Top

NOISELESSNESS is what designers are reaching for and it is one of the strong claims which has always been made by makers of electric vehicles for their products. In this, a certain amount of natural advantage is a normal expectation, owing to the absence of a power plant of the class involving the use of valves, reciprocating parts, and contrivances of a kindred nature, which make for unavoidable noise.

The natural advantage attending the performance of electric vehicles is not without a disadvantage, in that the very noiselessness of the electrical system accentuates every little sound, and the emanations which would not be noticed in other makes of cars become most annoying in electric vehicles. In going over this question, F. A. Babcock considered that his types of electrics would have to be so constructed that even the hum of the bevel drive in live rear axles would not be permissible. In order, however, to eliminate this slight source of noise, it was considered necessary to do away with the bevel gear, and so the Babcock Model 11 for 1910 is without a bevel drive.

Worm-Driven Rear Axle—In view of the excellent results obtained from worm-gear transmissions of the Hindley type, and realizing, of course, that this system is noiseless, the Babcock designers recognizing certain practical limitations, went into the matter of details at great length. The finished product shows the result of this special investigation and the modifications resulting, one result being the perfect "coasting" ability of the model 11 car, notwithstanding the fact that the average worm drive is nearly irreversible. Usually the worm will readily drive the wheel, but the wheel will not readily drive the worm.

The finished car, which is shown, was designed for town service, it being of the landau type. Referring to the other view of it, the car will be seen with the top down, and certain letters for use in ready reference to the design features as follows: A shows the electrical motor placed on the center line of the chassis, in the fore and aft plane, but with the customary ground clearance. B indicates the location of the electrical battery under the hood, which consists of 42 cells of 15 plates each, with a capacity of 140 ampere hours. C indicates a propeller shaft between the motor and the live rear axle, with double universal joints, D D, so disposed as to eliminate variations in the speed of rotation as well as to compensate for inequalities. E shows the housing of the live rear axle, just where the worn shaft enters and engages with the worm wheel.



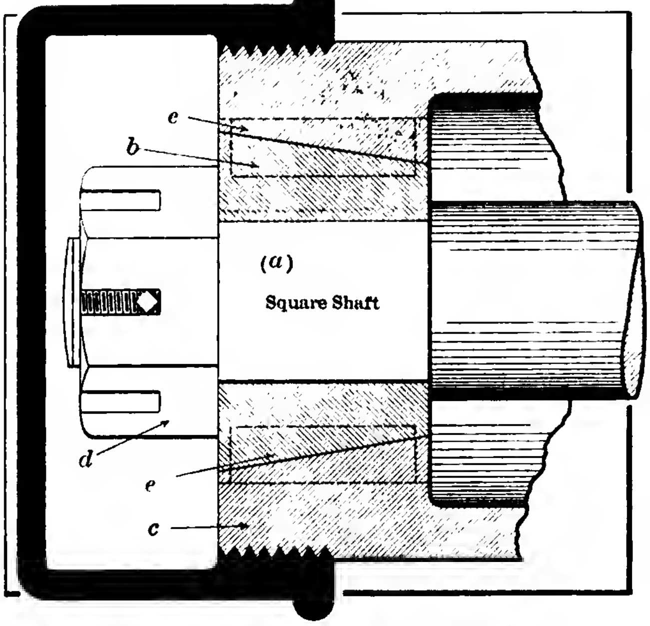
Diagrammatic Design of Babcock Model 11

The live rear axle, besides having a worm drive, houses a differential of the usual order, but there is one other new detail. The figure shows, in principle, the new idea, a represents the shaft, finished to a square, engaging a broached conical member b, which, in turn, engages a cone face in the hub c, due to the pressure of the nut d. Relative motion is prevented by the keys e, e. It is claimed for this drive, that it has all the advantages of floating, and that it cannot work slack, make noise, nor ultimately require repairing.

Annular Ball Bearings Used Throughout—To be consistent, and in order to carry out the plan of noiseless performance, it was decided to use a class of ball bearings which could not be adjusted. This idea assures that noise will not be the product of service, plus a "tinker" and a wrench, and the sizes of ball bearings were selected on a liberal basis.

Both front and rear springs are of the "Perfection" type, using Krupp special spring steel. The road wheels are 32 x 4 1-2 front and rear, and a trussed, laminated, wood chassis frame, imparts additional resilience to the whole body structure.

With a motor of great power; battery of ample output, it follows that good spring performance is desirable, and not only in order to please the purchaser by making riding enjoyable, but to eliminate battery troubles, by way of broken jars, loss of electrolyte, etc. In the meantime, in order to insure this performance under the most severe conditions, the Babcock designers, having located the most prolific cause of battery derangement, designed and adopted the plan of crating and holding the battery as shown. The oak crates, or trays, are in



Conical Drive in Live Rear Axle of Model 11

sets, and when the sets are put in place, the clamping device shown, delivers a uniform pressure on all the jars, independently of the crates, and prevents any relative motion at all.

Dual Method of Car Control—Referring to the wiring diagram, this shows a series motor five speed control, the connections, coming from the rear battery, lead to a drum type of controller, through the contacts numbered 7, 8, 9, and 14, and from the front battery to contacts terminals numbered 10, 11, 12 and 13. From 6, a lead passes to the motor armature, and thence, 1, 2, 3, 4 and 5 connect to the fields of the motor. Contact No. 1 also leads to the lever of the foot control, through resistances 31, 32 and 33, or evading resistance, when the lever 29 bridges to 30.

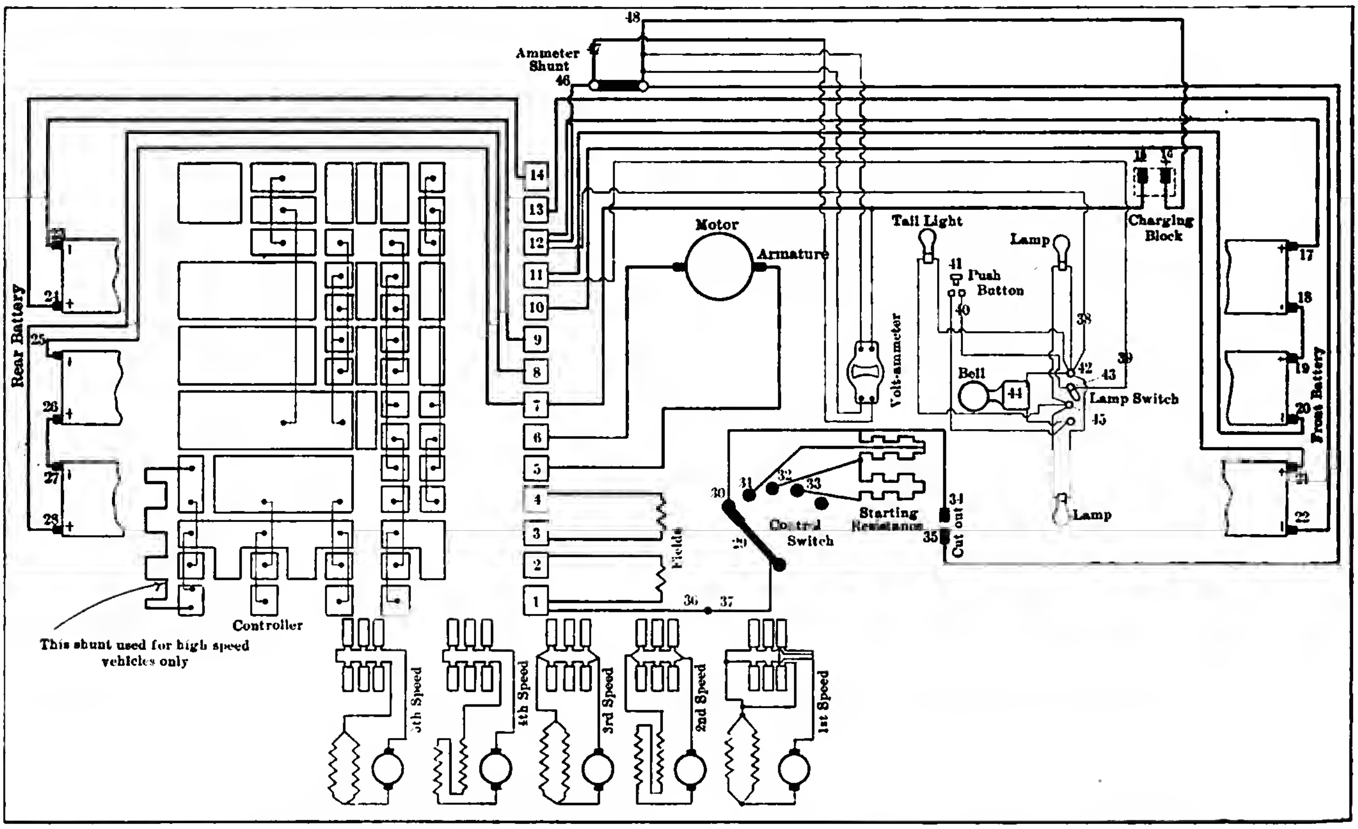
The several combinations required to give the first, second, third, fourth and fifth speeds, are shown at the lower part of the diagram, and remembering that the combinations may all be made in succession, by moving a single lever, the time will be propitious to divulge the use of the resistances as above referred to. It is obvious that the control might be made to serve without the resistance, which is but a matter of leaving the lever 29 in the position which bridges to 30, hence shutting off the resistances 31, 32 and 33.

Since the lever 29 may be worked independently of the drum control lever, the operator of a car has two choices, *i.e.*—the five separate speeds may be used by means of the hand lever of the drum control, without resorting to the foot lever 29, or with the drum control on any one of the five speeds, the foot lever 29 may be used to start, control, and speed the car, up to any limit fixed on the drum control. To go into reverse, however, it is necessary to throw the lever into the reverse position before the foot lever will be of any service. Of the remaining connections, little may be said, since they are for lighting, signalling, charging, metering, etc., nor would it seem to be necessary, at this time, to elaborate upon the advantages of electric lighting etc. The great question involves the principle of the use of separate resistances in the auxiliary control, thus rendering the operation of the car so simple and sure that ladies may drive with safety. Economical conditions obtain, since the resistances are merely auxiliary, serving to abort the consequences of forgetting how the controller may be set, and allowing free use of both hands in a tight quarter by substituting foot manipulation of the resistance lever.

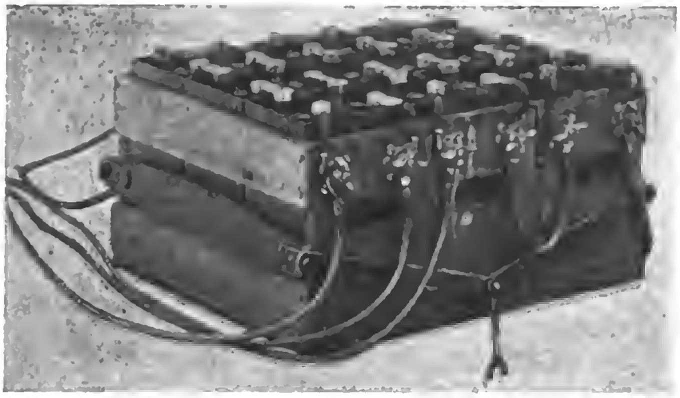
Details Are Worked to a Fitting Conclusion—The Babcock battery is of the type as originally brought out by Camille Fauré in 1881, but improvements wrought since that time, have reduced the whole to a wholesome basis involving qualities as follows:

(A) Considering a single motor drive, the greatest possible torque, and highest desired speed of the car. The torque realized assures that the car will negotiate deep snow, soft going, etc., while the speed on good roads is all that can be desired.

(B) The wiring system is protected at every point by the use of American Circular Loom, which is an insulator of permanence, and acid proof to all intents and purposes.



Wiring Diagram of All Models of Babcock Electric Carriages, Showing How Dual Control Is Carried Out



Babcock Clamping Lock for the Battery Cells

(C) All terminal connections are made of non-corroding Tobin bronze, sufficiently so to assure that bad contacts are not induced, and electrical troubles of this character are aborted.

(D) The sizes of conductors used are such that undue heating is not possible and the "drop" in the electrical system is therefore within economical limits.

(E) Speed combinations are as follows:

First speed: Three groups of 14 cells of battery in parallel, and motor fields in parallel.

Second speed: Two groups of 21 cells of battery in parallel, and motor fields in series.

Third speed: Two groups of 21 cells of battery in parallel, and motor fields in parallel.

Fourth speed: All cells of battery in series, and motor fields in series.

Fifth speed: All cells of battery in series, and motor fields in parallel.

(F) Flexibility of control, economy in the use of energy, insurance against mistakes of the operator, and absence of noise, without sacrificing harmony in any of the important relations, is the fitting conclusion.

Pedal control as outlined above renders the car more readily controlled, as, for instance, in the case of a woman driving, so that this method is bound to result in even greater popularity among the "weaker" sex, with whom it is already very popular.

AUTOMOBILE INVADES SOUTH AMERICAN HOSPITAL SERVICE

WHILE no one has ever set a limit upon the possibilities of the commercial car, it is generally supposed that it has a limit. What this limit is, is hard to ascertain, for every day sees some supposedly immune field invaded by the gasoline-driven car. Time was when the machines were noisy, but the silence of the modern car has done much to open up new opportunities for it. One of these is that of hospital service.

In this line, the superior speed and immunity to fatigue, give it at once a big advantage over the horse, as soon as the prejudice against the machine can be removed. This statement holds particular weight in warm countries, where the horses and other beasts of burden have their already small amount of usefulness still further reduced. The illustration below shows a car designed to replace the unreliable horse in a situation of this sort. It is the Pope-Hartford ambulance purchased by the municipality of Rio de Janeiro, Brazil. In this city, it supplanted several antique French cars. The body was mounted upon the regular chassis for commercial use, this being equipped with a 40-horsepower engine, three speed transmission, 130-inch wheelbase, standard tread, 34-inch wheels, 5-inch tires, and a special sixteen-gallon fuel tank.

Upon this chassis is mounted the body which was built after the specials plans by the Navy Department of Brazil. It is very striking in appearance, for instead of the dark colors generally used on ambulances, it is painted with a soft French gray. This makes it more appropriate for use in a warm climate. One of the features particularly distinctive of this ambulance is the top. Here an entirely new idea has been put into effect. Instead of the closed roof, devoid of any means of ventilation, usually employed, this ambulance has what is called the "trolley" top. In this the top is carried up a little way above the sides, giving room for four oblong windows on each side and two both in front and in back. This adds wonderfully to the comforts of those within and gives the machine a distinctive appearance.

Upon the interior has been spent even more time than on the exterior, for as a matter of fact, any old outside would do, if only the facilities for handling patients were adequate.

Its inside finish is in mahogany and is very roomy. There is every conceivable contrivance for the comfort of the sufferer. The details of inside equipment are as follows: Four beds with springs and mattresses made of best curled hair and covered with plain leather. These beds are arranged on slides and rollers so that they can easily be taken in or out of the wagon, and a locking device is provided so that they can be held firmly at any position. There are four stretchers of rubber cloth and four pillows similarly covered. Two medicine chests are provided with compartments for the physician's case, cotton, and splints. There are two folding seats for the nurses, surgeons, and attendants.

Long wheelbase, large wheels, large diameter tires and proper springing will go far toward making this car ride easy, as easy as would be necessary in a vehicle for transporting the injured, while a special gear ratio allows of high speed, as in the case of a hurry-up call, accidents, poisoning cases, etc.

Special Pope-Hartford Ambulance for Brazilian Navy Department

AFTERMATH OF THE LONG ISLAND STOCK CHASSIS DERBY

LONG ISLAND roads have been famous since the earliest days of automobiling, and have been made classic by the Vanderbilt Cup races, yet few, even of those who knew them best, supposed that they would yield such a marvellously fast course as that which connects in triangular fashion Riverhead, Mattituck and Centerville. There had been the usual advance reports of fast time made in practice, and these had been taken with the proverbial grain of salt. The awakening, however, came in the very first lap of the September 29 race, when the time of the three-year-old Mercedes formerly owned by W. K. Vanderbilt, Jr., was announced as 19:20, a speed of 70.5 miles an hour for the 22.75-mile course. Chevrolet and his Buick came not so far behind, with a record of 69.2 miles an hour. The same combination made the fourth lap in 17:40, a rate of 77.3 miles an hour, and finished, as everyone now knows, at an average speed just short of 70 "per."

The grandstand received the first notifications incredulously, and Announcer Prunty was requested to repeat them several times. After the race the Motor Contest Association gave out that the surveyor who measured the course had filed a sworn statement attesting that the length was really 22.75 miles, measured on the crown of the road, and that the steel tape used had been sealed by the supervisor of weights and measures. Thus the correctness of the measurement seems well attested. The timing was done by the Warner electric timing machine, presided over by the inventor himself, and supplemented by the New York Timers' Club, which obviates any possibility of error on that side.

Where Officials and Pressmen Performed Their Duties

Course Was Excellent
De Palma's Fiat in Flight

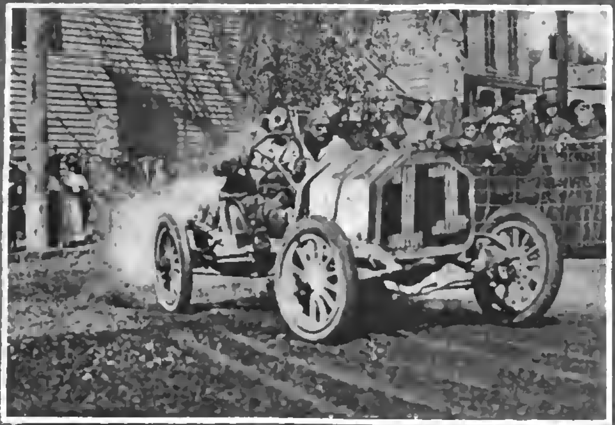
One explanation of Chevrolet's fast time is, of course, the shortness of the race, as the class he was in only went five laps, 113.75 miles. This enabled him to finish without having made a single stop, either for tires or gasoline. Many rumors have been afloat concerning the genuineness of the Buick's claim to be a stock car, but the Buick team has passed the scrutiny of several different technical committees without having been found at fault. Of course the A.A.A. rules for stock cars only specify that twenty-five of a given model must have been made, and it is easily possible for a concern which intends to go in extensively for racing to make twenty-five special cars, call them stock models, and not lose much by it.

Lytle on the Road to Recovery—Herbert Lytle, the plucky driver of the Apperson "Jack Rabbit," is reported to be practically out of danger. He is still in the Eastern District Hospital, at Greenpoint, L. I., but is expected to be well enough to leave in a few days. The surgeons say that he suffered more from shock than any other cause, and the internal complications at first feared have as yet failed to appear.

No authoritative explanation of the accident has been made. Some reports say that it was a plain case of skid. All, however, agree that the Apperson was going at high speed at the time, probably 70 miles an hour.

The American Hot Springs—The American roadster driven by Hugh Hughes caused some excitement in the grandstand when it stopped at the end of the fifth lap. A jet of steam over the radiator cap proclaimed that the engine had become overheated through some derangement in the cooling, and the mechanic, arming himself with a big bunch of waste, leaped to the ground the moment the car stopped and got busy with the cap. When he finally got it off a geyser of hot water, steam and mud shot up twenty feet high, sprinkling the onlookers in the nearby boxes. There was some shaking of heads when the mechanic immediately began pouring in cold water, and many predicted that the American would be put out for good by a cracked cylinder. No ill results became apparent, however, and the American was still running when the race was brought to an end.

Daring Work of Mechanic—Herbert Bailey, the mechanic on Disbrow's Rainier, pulled off a bit of work which marks him as a future driver of no little promise. At least he possesses the requisite agility and nerve. The most hardened racegoers gasped with amazement when the Rainier sped down the homestretch and stopped in front of its pit with Bailey clinging in some miraculous fashion to the radiator and the front spring irons, holding the steering gear together. On the sixth lap, just after leaving the grandstand, a pin came out of the cross-link of the Rainier's steering gear, leaving the left front wheel adrift. It was, of course, impossible to steer the car with control over only one wheel, so Disbrow and Bailey strapped the link back in place. The repair did not look very secure at that, and finally Bailey climbed on to the spring hangers to hold it in place. He



Chevrolet, Who Averaged 70 Miles Per Hour

Arthur See, Maxwellite, Small Car Winner

needed both feet and one hand to hold himself on the car, but with the other hand he got a good grip on the link. He maintained this precarious position for twenty miles. The Rainier made the lap in a trifle over twenty-six minutes, and Disbrow afterwards said that he did not even slow down for the turns.

The Sharp-Arrow Forgot to Stop—William Sharp's Sharp-Arrow was literally "in a class by itself," and had no trouble winning the trophy for cars selling between $2,001 and $3,000. It finished its specified six laps in 2:09:02, a rate of 63.6 miles an hour. Sharp liked the going so well that he kept right on after he had officially finished, and completed three more laps. Some of the spectators did not know that he had finished, and asked for his time, whereupon Peter Prunty informed the grandstand that the Sharp was "just touring." When Starter Wagner finally ordered it off the course it had a five-minute lead on De Palma and his Fiat.

Another Race Next June—It is unofficially announced that another race will be held over the Riverhead course some time next June. Certainly this new course is too good a find to be allowed to drop back into obscurity. Without doubt it is the fastest course in the country. The roads are of loam and sand, but rolled hard and smooth and plentifully oiled. They seem to be especially easy on tires. There is some doubt as to how the surface would stand the strain of some twenty heavy cars at full speed for ten or more laps, but for comparatively light cars and short distances it is certainly unexcelled.

Senator Morgan said immediately after the race that he would retire from participation in such events, but when assured that the accident was in no way the fault of the course he reconsidered his decision, and will probably have charge of the race next June. Many contingencies remain to be provided for; the consent of the county officials must be obtained, and another sanction must be issued by the A.A.A., but every effort will be made to give the racing teams another chance to show what they can do on the Long Island circuit.

Nearly All Cars Made Good Time—With remarkable uniformity nearly every car except those in the smallest class made at least one lap in excess of a rate of a mile a minute. The old reliable Mercedes scored one lap, the third, in 18:49; De Palma's best was the seventh, done in 20:56. Disbrow's Rainier made the second lap in 21:53, and his comrade Lund drove the sister car over the third lap in 22:00. By a coincidence Disbrow and Lund both made the second lap in 22 minutes flat. The Palmer-Singer, the only six-cylinder car in the race, made a record of 20:05 for the second lap, and the Sharp-Arrow, not far behind, covered the third in 20:56. Chevrolet made the fourth in 17:40, and Burman's best was the second, in 19:50. Most astonishing of all were the times recorded by the little Maxwells; See covered the course in the time of 25:03 and Costello in 25:43, both at the rate of about 54 miles an hour.

MANY CLUBS FORMED IN COLORADO

Denver, Colo., Oct. 2—There has been much activity in this part of the country in forming new clubs, and in this the Denver Motor Club has taken a considerable part. Among the organizations recently reported are the automobile clubs of Greeley, Ft. Collins, Boulder, Longmont, Colorado Springs, Pueblo, Trinidad, Canyon City, La Junta, Ft. Morgan, Julesburg, Rocky Ford, Florence, Las Animas, Grand Junction and Glenwood Springs, and those of Cheyenne, Wyo.; Tulsa, Okla.; Garden City, Kan., and Imperial, Neb.

Mercedes (Armstrong) Withdrawn Because of Accident

Herbert Lytle's Apperson After the Fatal Plunge

A Picturesque Roadway That Is Part of the Course

PHILADELPHIA, Oct. 4—The first gun of the coming contest for the honors in the Fairmount Park 200-mile stock chassis race next Saturday was fired this morning when the 7.8-mile course was opened at daylight to a dozen or more anxious entrants who were on the ground to try out their cars and become acquainted with the course. There are twenty-one entries in hand, with one, and possibly two, additional starters, which will be announced later. At a meeting of the contest committee of the Quaker City Motor Club last Tuesday evening, the entries of Bergdoll's 120-horsepower Benz and Barney Oldfield's car of the same make, which he entered as of 59.6 hosepower, were rejected, it being the opinion of the majority that the cars did not meet the official specifications of a "stock" machine.

The lineup will include some of the most famous track and road drivers, including Robertson, with a Simplex; Dingley and Lorimer, Chalmers-Detroit; Grant, Alco; Haupt, Thomas; Zengle and Parkin, Chadwick; Wallace, Palmer & Singer; Chevrolet and Burman, Buick; Lytle, Apperson (if he recovers from his recent injuries in time), and several others almost equally as well known.

An examination of the course Saturday showed that it was in 50 per cent. better condition than last year, when not a little new road had to be hastily constructed to round out the circuit. The stretch along the South Concourse is absolutely flawless, as is the combination hairpin-S turn on Sweet Brier Hill. Almost the entire stretch of three miles of the river road along the Schuylkill, which was the worst portion of the course last year, has been worked on until it is in nearly as good condition as the Concourse. The bad turn under the Chamounix bridge has been improved, too, but it is still somewhat lumpy for fast work. After practice hours a gang of men will be kept at work at this point all this week. City Line avenue, as usual, is in the best of condition, while Belmont avenue is being worked upon to get it into mile-a-minute shape. At a previous inspection of the course the committee induced the Park Commission to remove several telephone poles and fire-plugs located at turns, and which, in the event of a bad skid, might cause trouble. All in all, the course will be as safe as human ingenuity and hard work can make it. The main feature which makes for safety is the boulevard width of the roads throughout almost the entire circuit. Fast cars cannot be held up by slow ones, and in this respect alone the course is the fairest in the country.

That the largest crowd that has ever witnessed a similar contest will be on hand next Saturday afternoon is positive. The homes of a million and a half of people are within a five-cent carfare ride of the course, and the half-holiday will bring out every man, woman and child who can get on a trolley car. The police arrangements, as personally looked after by the Mayor and Superintendent of Police Taylor, are perfect. Fifteen hundred policemen, reinforced by miles of rope and wire fence, will keep the course clear, and additional guards and flagmen will be furnished by the Quaker City Motor Club. At dangerous turns, such as at Sweet Brier Hill, at Chamounix railway bridge and at the Catholic fountain, special care will be taken to protect the public.

Many parking spaces and grandstand boxes were disposed of at public auction last week, not a few of the former bringing 200 per cent. more than the regular price. Many of the boxes also brought good figures, and the expectation of the promoters that at least $20,000 will be turned over to the four charitable institutions which have been named as beneficiaries, seems in a fair way of being realized.

The main stand is ready for its decorations, and a large gang of carpenters is at work on the official and press stands and repair pits. The latter will be located above and below the tape, directly in front of the big grand stand, thus affording the spectators a fine view of the exciting features attendant upon quick tire changes, taking on of supplies, etc.

'Phone stations will be established at various points around the course, and the scoring arrangements have been under rehearsal for the past fortnight, to insure the prompt and correct recording of the work of the various contestants. The score-board itself will be a vast improvement over last year's crude affair, which came in for no little deserved criticism. A specially drilled corps of men will have charge of the board, while the Warner Instrument Company will supplement the work of the scorers with its patent recording device, which shows the relative positions of the three leading cars.

LIST OF ENTRANTS

No.	Car	Cyl.	H. P.	Bore and Stroke	Driver
1	Acme	6	60	5x5	Malin Leinau

HOOSIERS ENJOY SOCIABILITY RUN

INDIANAPOLIS, Oct. 4—Local owners and drivers held a combined sociability run and hill-climb last Saturday and Sunday, which proved such a success that it is hoped to make it an annual affair. The run was to Mudlavia Springs and back, and a handsome silver trophy, hung up by the Warner Instrument Company, was to go to the driver who made the trip in time nearest a secret schedule. Twenty-three entries appeared at the start. The first car left Indianapolis at 7 o'clock Saturday morning, and was due to arrive at Mudlavia Springs in time for lunch. The others followed at one-minute intervals. The Marmon confetti car, driven by Bernard Saltzgaber, was ditched between Crawfordsville and New Richmond, and Mr. Saltzgaher was slightly hurt. The accident was not so serious as to affect the pleasures of the day.

Saturday afternoon a hill-climbing contest was held on Devil's Elbow, which was won by Carl G. Fisher, driving a Stoddard-Dayton. The return trip, by way of Lebanon, was 104 miles in length. After the return to Indianapolis it was announced that the trophy for the nearest approach to the schedule time had been won by Miss Katrina Fertig, driving a Premier. Her time varied but one minute three seconds from the schedule.

These guessing tours have been a prominent feature of the various Premier tours of the year, and have attained popularity.

Atlanta Will Supply Southern Hospitality

The New Auditorium-Armory Where the First of the Southern National Shows Will Be Held

ATLANTA, GA., Oct. 4—That the citizens of Atlanta are determined to live up to their famous reputation of Southern hospitality and make the Atlanta Automobile Show a record breaker and one to be remembered, is best evidenced by the manner in which professional and business men of the city are contributing to the fund to be used for entertaining the visiting manufacturers, salesmen, and others who attend the Atlanta Show. Already over $15,000 has been received by the executive committee, and by the time the guests begin to arrive this amount will be increased by many thousands.

Atlanta has been a little envious of her sister city, Savannah, ever since the latter city held the Grand Prix races last Thanksgiving day and took such good care of her visitors. Atlanta now sees a chance of outshining Savannah's hospitality and is doing her utmost to beat all records for entertaining those interested in the motor car industry. That she will succeed is admitted by those cognizant with the plans being prepared.

For a city the size of Atlanta it means a hard task to house the great influx of visitors who will attend the show, and to meet this exigency a public comfort department has been created with S. C. Dobbs, of Atlanta, as chairman. This department will find temporary homes for those attending the affair. A general call has been sent out to the citizens of Atlanta to open their residences to the guests, and hotel proprietors are making every effort to increase their facilities. A general renovation is in progress, and the hotels from now on will be in the hands of decorators and painters putting the Atlanta hostelries in the best of condition.

Invitations will be sent out to every dealer and garage proprietor in the District of Columbia, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Texas, Alabama, Mississippi, Louisiana, Arkansas, Missouri, Kentucky and Tennessee.

In addition these, which number about 1,100, will be issued invitations to all carriage dealers in the same States, swelling the number to about 2,000. The courtesies of the show will be extended to these dealers gratuitously. As is well known, the show is being held at the time of year when money is free in the South. The planters have harvested their crops and will receive about $120,000,000; banks have increased surpluses, merchants and store proprietors have done a good business, and, in brief, practically all the Southern higher class are in a position to, and will, buy motor cars and accessories. All this makes doubly sure the success of the Automobile show.

Racing on the Great Speedway—The great $300,000 two-mile automobile speedway of the Atlanta Automobile Association was turned over to the owners by the contractors on Saturday last. Monday morning the experts of the Standard Oil Company began their work of oiling the track. This work will probably consume one week's time, and then the track will be ready for the racing men, who will give it the first official test. The management of the Atlanta track is determined that there shall be no imperfections in the track if they can possibly be avoided, and it is with this object in view that they have secured the services of such noted drivers as Robertson and De Palma to visit Atlanta and make an inspection of the track.

The work on the grandstands is progressing to such an extent that they are to-day ready for occupancy, and the bleachers will be finished before the end of the present week. The garages—75 in number—are constructed of corrugated iron, and each one will be provided with all modern conveniences.

The star event of the great five-day meet to be held from November 9 to 13, inclusive, will be the 200-mile stock chassis race for cars from 451 to 600 cubic inches displacement. This race will be for the City of Atlanta trophy, valued at $10,000. In addition to the trophy, the winner of this race will receive $1,000 in gold; second prize, $500 in gold; third prize, $300 in gold; fourth, $200 in gold. In addition, there will be other races at shorter distances for various sized cars, together with special match races, pursuit races, etc.

THE AUTOMOBILE

WHAT ABOUT OFFSETTING?

One of the stock questions of the past three or more years has been that of the most advantageous offset. Beginning at the time when the practice of setting the cylinders off of the center line of the crankshaft, that is, *de saxe*, as the French have it, there was much argument, pro and con, as to the merits of this practice. The result seems to have been that it won a certain place in the industry; that is, some manufacturers thought it worth while and took it up. Others, and they are numerous, granted the contention that the practice was all right, but would not and do not use it to-day. However, the advantages having been granted, the later question for discussion became the most advantageous offset.

New light has been shed upon this perplexing subject by the results recently published, for the first time, of a number of experiments made for the express purpose of settling the argument. The conclusions deduced from a number of tests of large gas engines, differing only in size and relative weight from automobile engines, are most interesting in that they seem to shed light not only upon this problem, *per se*, but also upon the equally perplexing one of the two-cycle engine. A statement of these conclusions will make this clear, as follows:

A. An offset cylinder may be employed with *least* benefit on a high-speed, four-cycle, vertical engine.

B. It may be employed with the *most* benefit on a slow-speed, two-cycle horizontal engine.

C. The maximum advantageous offset is limited by the side pressure near the beginning of the first stroke, regardless of cycle.

The italics are ours, put in to bring out the desired point; that is, the tests would seem to show that the practice of offsetting is of the greatest utility as applied to the two-cycle motor. From this it is a reasonable deduction that its use in that form of engine will increase the power output of any given unit. This will be of much benefit, since that form has been sadly lacking in this department, for, far from developing an excess of power over the corresponding size used four cycle, in the vast majority of cases there is a large and very noticeable lack of what might even be called equality.

True, the investigator has made the point that the most gain is found in the horizontal type of two-cycle engine, of which very few are built, but it is logical to deduce backwards from this to the statement that the two-cycle vertical would present the next best amount of advantage, using the practice of offsetting. This idea, taken at its full worth, in combination with some one or more of the other modern notions, such as the differential piston, the rotary valve, the slide valve, or fuel injection, should evolve a new and superior type of two-cycle power plant.

NEW YORK SEES WRIGHT FLY

Aviation had its first really public demonstration when Wilbur Wright circled the Statue of Liberty and flew from Governor's Island to Grant's Tomb and back. Other great aeroplane flights have been made on closed fields, or, if in the open, in comparatively secluded localities. Now, for the first time, an aeroplane has flown past a great city, revealing itself to the multitudes in the streets. Several hundred thousand people must have witnessed the flight. Crowds looked on from the Battery, from Riverside Park, and from the wharves on either side of the Hudson; other crowds saw it, at a greater distance, from windows and the roofs; ferryboats stopped in mid-stream, their decks black with passengers staring upward; the crews of the French, German and English warships, at anchor in the stream, lined the yard-arms and cheered.

Considered scientifically, the flight must rank as among the best yet accomplished. Bleriot's passage of the English Channel was longer, both in time and distance, but the course lay over open water; the French aviator's only difficulty lay in crossing the line of English cliffs. Wright, on the other hand, flew the whole distance in close proximity to New York's towering buildings.

TWO-CYCLE SHOWS UP WELL

Advocates of the two-cycle form of construction are elated over the showing made by the Elmore and the American Simplex in the Munsey reliability run. These cars won their classes, and the Elmore won, in addition, the cup for the best performance. It made the remarkable record of being the only car both to finish the run with a clean score and to go through the technical examination unpenalized. In France, too, the two-cycle engine is regarded with more favor than formerly. A car of this type held third place in the voiturette race at Ostend for nine of the twelve laps, being forced to retire by a broken wheel.

SOME COMMENT OF THE MOMENT

President Schurman of Cornell may or may not be an autoist, but he is something of a satirist, judging from a most recent utterance which found its way into print upon his return from Europe. During his travels abroad the distinguished factor in education observed that the aeroplane had produced evidence of its undoubted worth. "The possibilities of flying are so wonderful," said the Cornellian, "and the marked advances of the past summer so promising, that some day the rich young society youth may abandon his automobile for a flying car, thereby leaving the roads to the public again." Dr. Schurman said he looked forward to the time when the roads should be open to "you and me" again. When that day arrives the Doctor will find the great army of law-abiding autoists celebrating with him the disappearance from the roads of the small but inconsiderate contingent which hogs the highways in a criminally reckless manner. In the jailing that must take place there will be others besides rich young men of demoralizing leisure, for while this class is to be seen numerously, the guilty embrace all classes. Sky travel may help to lessen the offenders, but the most efficient remedy is to compel every driver of an automobile to obtain a license, the abuse of which may lead to temporary or permanent revocation.

But there is a natural sequence even for the rational autoist to add flying to his accomplishments, and the industrial phases of these two pastimes have much in common. A recent illustration is W. D. Gash, one of the John Wanamaker department store commanders. Once upon a time Mr. Gash had to do with the making of Orient bicycles, and then motorcycles. Next he figured as a sales manager of the Searchmont, one of the earliest American efforts in automobile manufacture. Subsequently he completed the arrangement whereby John Wanamaker undertook the selling of Ford cars, which idea did not assume the proportions anticipated. When the plan was discontinued, Gash remained in the Wanamaker employ, and now among his varied duties he is giving some attention to the flying machine exhibition at the New York store. Mr. Gash was one of the charter members of the Aero Club of America, and has attended all of its important functions, as in like manner he has continued to keep more or less in touch with automobiling by being present at leading social events and classic competitions.

The first cash prize ever offered in this country in an automobile race was over a year ago in a gruelling 24-hour race at the Brighton Beach track in New York City. Montague Roberts, the winner of the race, in a Thomas car, is still looking for the $1,000 which was supposed to go to the winning driver. In the meantime William H. Pickens, who vouched for the business integrity of one Joseph Gaites, continues to serve as the manager of the racing team of one of the most prominent concerns interested in racing. While the metropolitan club which officered the meet had no business connection with it, except to receive a percentage for its work, it would be an act calling for much commendation if it contributed the sum toward the meeting of the obligation. Pickens ought to be relegated to the side lines until either he or his theatrical ex-partner produce the unpaid prize. "Heads I win and tails you lose" is flimflam in whatever channel it is practised, and the payment of prizes only when sufficient money comes in at the gate is a thing not tolerated when sport has real government. The improved conditions since the M. C. A. became a factor should include a demand for the settlement of a prize the continued neglect of which is little short of exasperating to the man who should receive it. It speaks well of the winning driver, who did not win, that he has never made a "holler" for the money, nor stirred up a "fuss."

The old Porter House in North Cambridge, Mass., is to become a garage; here it was that the fame of the Porter House steak began. The husky eaters of Boston Town, when their vigorous appetites demanded substantial attention, journeyed to the old Porter House, and many a man—and woman, too—who has enjoyed this succulent cut of the beef will learn for the first time upon this reading the source of its naming. Bostonian chronicles tell not the name of the man who first carved this cut nor the fortunate one who ate it; but it is a matter of record that in the years following its advent the procession of patrons of the Porter House grew in great numbers, and in the ranks were men of note in the affairs of the commonwealth. And now the smell of gasoline is to replace the delicious odor from the grill, with resultant pangs of hunger to those who now will have to search elsewhere for a less historic source at which to appease their longings, for it should be said in the passing that the old Porter House had survived a century and a bit more.

A new wrinkle in the way of automobile persecution in England is the inclusion of the passenger when arrests are made for so-called overspeeding. In a recent happening in the tight little isle a passenger accompanying an arrested driver was mulcted to the tune of £4, which, in good American money, means nearly $20. In this revised method of apprehending offenders it is not improbable that good results may ensue, for the occupant of the tonneau, when time hangs heavily on his hands, might employ as much persuasiveness as he can summon, verbally and physically, in urging the man at the wheel to lessen his pace so that he will keep within the confines of the law. In some instances the plan might be an excellent one, though it is pretty good guessing that it will not be astonishingly efficacious as a general rule.

One of automobiling's phases is the gradual loss of the so-called "speed-fever" by the older drivers, who nowadays seem to drive quite slowly, even on a good road, instead of extending their cars to find out exactly what they are capable of when utilizing all their power. There are times when one may drive fast, and there are times when one should drive slowly. Discretion in both cases tells whether one is a good or a bad driver.

Automobiling Has Made the Road Signs of France Comprehensive and Concise

SELDEN DECISION BRINGS STARTLING RESULTS

(*Continued from page 591*)

To-day's Meeting of the Licensed Association

The A. L. A. M. has its regular monthly meeting to-day, and all these matters of great moment will come before the association. None of the officers of the Licensed body cared to be quoted in advance as to the probabilities, contenting themselves with the expression of an opinion that a broad view was being taken of the entire situation and that the general good of the industry was to be considered. This has been the open expression of Colonel Charles Clifton, president of the Licensed body, for some time past, though he encountered some difficulty in convincing others of the wisdom of his course. His advice is likely to be quite potential at the present moment.

Two Shows Are Still Assured

Believing that two shows are a necessity in New York City, it is probable, no matter what the outcome will be in clarifying the situation, that there will be no interference with the announced plans for the holding of the shows in Madison Square Garden and Grand Central Palace, the latter under the auspices of the A. M. C. M. A. One building could not possibly house all the exhibitors, and thus two separate shows become an actual necessity.

The National Association of Automobile Manufacturers yesterday held a meeting for the purpose of allotting space for the Chicago show, and to-morrow the A.M.C.M.A. will have its drawing for the Palace exhibition.

BAY STATERS TO HAVE AN ENDURANCE

Boston, Oct. 2—The contest committee of the Bay State Automobile Association has announced the preliminary plans for an endurance run to be held Friday and Saturday, October 22 and 23. The primary object of the contest will be to give the people of many of the principal cities of New England an opportunity to see the 1910 models in operation and to make comparison of their performances under uniform conditions. According to the plans that have been made, the run will cover approximately 450 miles, the contesting cars making half the distance on each of the two days. On the first day the cars will pass through the cities and larger towns to the south and west of Boston. The route includes Quincy, Holbrook, Brockton, Bridgewater, Middleboro, New Bedford, Fall River, Taunton, Providence, Pawtucket, Woonsocket, Fitchburg and Worcester. The second day the run will be to the north and east of Boston, the principal points on the route being Lowell, Nashua, Manchester, Concord, Dover, Portsmouth, Newburyport, Haverhill, Lawrence, Salem and Lynn. At the end of the road test the cars will be examined by a technical committee.

NOVEMBER MEET ON BRICK SPEEDWAY

Indianapolis, Oct. 4—The aviation meet which was to have been held at the Indianapolis Motor Speedway, Oct. 14, 15, 16, has been abandoned, owing to the inability to reach satisfactory terms with Glenn H. Curtiss, who refused to participate for less than $12,000. However, the speedway management has arranged for another automobile race meet for November 1, which will be the first held on the new brick course. The work of paving the course is proceeding rapidly.

WAGNER AND AMES BUY "HORSELESS AGE"

One of the pioneer automobile journals of the country, *Horseless Age*, has been purchased by Fred J. Wagner, formerly of *Motor Age*, and C. B. Ames, of *Motor*. Both are well known in the industry, and under their capable direction the property should receive the up-to-date attention of which it has been in need for some time.

PALACE SHOW HAS RECORD LIST

All records have again been broken in connection with the application for space in the Tenth International Automobile Show, which will open New Year's Eve in Grand Central Palace, New York. When the applications for space to participate in the first allottment closed 110,000 square feet had been applied for, which is about 5,000 square feet more than was applied for last year. With but 72,000 square feet at their disposal, Chairman R. E. Olds and his associates on the Show Committee will experience considerable trouble satisfying the demands of motor car and accessory exhibitors.

Members of the A. M. C. M. A. have fairly swamped the management with requests for increased space, and members of the Importers' Automobile Salon have taken every foot contracted for by that association. David J. Post, who represents the Motor and Accessory Association, is authority for the statement that members of his association have applied for 25 per cent. more space for the Palace affair than at any previous exhibition. The drawing for space will be held at the headquarters of the A. M. C. M. A., 505 Fifth Avenue, New York, at 10:30 o'clock to-morrow.

Opening the 1910 show season the Grand Central Palace as usual will be the first in which are exhibited the products of many new concerns, both motor car and accessory manufacturers. The great quantity of new exhibitors this year has impressed the Show Committee with the growth of the industry since the Grand Central Palace Show of last year.

PLANNING FOR A SHOW IN COLUMBUS, O.

Columbus, O., Oct. 2—At a recent meeting of the Columbus Automobile Club it was decided to hold an automobile show in this city some time next January or February, and a committee was appointed, consisting of Perin B. Monypeny, Fred H. Caley, Herman Hoster, N. O. Aeby and O. H. Perry, to make the necessary arrangements. All manufacturers will be invited to participate, and it is expected that the date will be arranged between those of the Cleveland and Cincinnati shows, so that manufacturers will not be forced to go to unnecessary transportation expense.

The "Old People's Day" proposed by several members of the club has been postponed till next year because of the lateness of the season.

"LUMMY" GOES BACK TO "LUNNON"

A. E. Lumsden, London representative of the B. F. Goodrich Rubber Company, sailed for home Saturday last on the *Cedric* after a two months' visit in this country. The success of the London branch of the Goodrich company is attested by the fact that it has now been in existence for several years under the able direction of Mr. Lumsden, who will be remembered as one of the old-time bicycle champions of America, his base of operations having been Chicago. It is like carrying coals to Newcastle to sell tires in Europe, and salesmanship enters into the proposition as much as quality of goods. Apparently "Lummy" knows how to sell things, and he has something good to sell. He was accompanied on his visit by Mrs. Lumsden and son, and part of the time was spent at Christmas Cove, Me., at the summer home of Mr. and Mrs. S. A. Miles.

NEWCOMERS IN THE INDUSTRY

Detroit, Oct. 2—The Sibley Motor Car Company has been organized and incorporated under the laws of Michigan to manufacture a popular-priced touring car and roadster. Plans are being developed for quantity production to begin early next year. The incorporators are: Frederick M. Sibley, Henry Wineman, Jr., John G. Utz and John B. Phillips. Mr. Utz and Mr. Phillips were formerly associated with the Chalmers-Detroit Motor Company as chief engineer and superintendent.

INDUSTRY AS VIEWED BY HEADS OF ONE BIG CONCERN

GREATER DEGREE OF CO-OPERATION DESIRED

By H. H. Newson, General Manager McCord Manufacturing Company.

The builder of automobile parts is no longer a manufacturer who blindly supplies whatever may be called for by the specifications and blueprints of his customer, but is in the position of an active department of the customers' organization, and consequently must often act in an advisory capacity. The result of this condition is shown by the testing plants and laboratories maintained by many of the parts manufacturers. For instance, the manufacturers of radiators to-day are no longer asked to build a radiator according to certain exact specifications, hut often are given merely the outline, the location of inlet and outlet castings and engine dimensions and asked to design a radiator to cool efficiently. I believe that a great deal of annoyance could be avoided if this idea were put more into practice, as it is certainly reasonable to suppose that an organization which spends its entire time on practically one subject should be better posted on this subject than the man who designs one or possibly two radiators a year. This calls for a full knowledge of not only the radiating efficiency of one's own type of radiator, but also of the various other makes in use as well as complete data relative to the entire question of cooling gasoline motors. The lack of information on these subjects even by the best posted automobile builders has been surprising, and now that there is a decided tendency toward the use of the thermo-syphon system of water circulation, the need for a thorough knowledge of the subject is greater than ever.

Another matter of great importance is the testing of the product by the parts manufacturers before delivery to the automobile makers, as nothing disrupts an organization and delays an output so much as the necessity for returning parts on account of defects, even though they may be minor ones. One of the greatest single items of expense in the production of such parts as lubricators and radiators is this item of testing, as the system maintained must be thorough and to a certain extent elaborate. A great many automobile builders would be very much surprised to know the expense of testing radiators, to make certain that they are absolutely tight before they are applied to the customer's car.

The ultimate result, of course, will be a greater degree of co operation between the motor-car builders and the parts makers, and it is plain to see that this is a most desirable condition. There are many parts which probably always will be made by factories independent of the automobile factories, as unquestionably the specializing induced by this condition permits of decidedly better results. The parts makers view the situation from this standpoint and are laying their plans and establishing their factories and organizations accordingly.

HEAVY CARS STILL MUCH FAVORED

Cleveland, Oct. 4—The growing popularity of light cars has failed to convince George J. Dunham, president of the Royal Tourist Company, that this type is superior to the heavy models, and this company will continue in 1910 to be one of the few in this country which has not brought out a car of light, or, at any rate, medium weight. The 1910 Royal Tourist, designated Model M, Series Two, will have a 5 1-2 by 6-inch motor, rated at 48.4 horsepower, and claimed to develop 65. There have been but few changes; the motor is the same, with the exception of the oiling system, which is of an improved circulating type. The hood has been lengthened and the dash is now square. Alloy steel is used for the frame, axles and gears, and by improved methods of construction it has been found possible to build a large seven-passenger car of comparatively moderate weight and capable of economical operation. Preparations are being made at the Royal Tourist factory to meet a heavy demand.

PARTS FACTORIES WILL BE ILLUMINATED AT NIGHT

By P. L. Barter, Sales Manager McCord Manufacturing Company.

The enormous and marvelously quick growth of the automobile business is a topic of interest throughout the whole country, but in Detroit the situation is more focused in the public eye than elsewhere owing to its increasing number of factories.

This situation provides a greater problem for the parts makers than for any one else in the business, due to the fact that a majority of the cars produced during the next year will be wholly or partially assembled, and that in very few cases will all the complete parts be built in one factory. There are, of course, many parts of an automobile that cannot be produced by inexperienced manufacturers, and so as a matter of fact the output of cars to a large extent will depend upon the output of the factories of the established makers of standard parts.

The ability to "deliver the goods" is the main factor in this business to-day, and it is reassuring to note that the leading manufacturers of parts have anticipated this situation by adding to their factory space and equipment to care for the increasing demand. That the "live people" are meeting the situation satisfactorily is undoubtedly true, and the wise and well-organized concerns are only taking on such business as they can actually produce.

That there will be any serious famine is doubtful, but that the parts factories throughout the country will be illuminated at night for the next twelve months is unquestionably a fact

On the whole, never has the outlook been as favorable as at present, and while there are murmurs of future disasters from the ever-ready pessimists, those who undoubtedly are closest to the great buying public tell us that the upward wave will not reach its crest for the next two or three years, and by that time the situation will have been thoroughly clarified and reduced to an ordinary basis.

The more the sane business side of this great industry is accentuated in the press and in the mouths of those composing the trade, and the less stress is laid upon its quick profits and spectacular features, the more quickly will come the result we all anticipate and desire. We believe that even the advertising should reflect a spirit of conservatism and careful business forethought, tending to more and more spread a belief in the stability of the entire industry

QUAKERTOWN'S P. O. EMPLOYS AUTOCARS

Philadelphia, Oct. 4—On Friday last the local post office authorities put into commission five Autocar motor trucks, to be used in collecting mails in the northern and western sections of the city. So promptly and thoroughly was the work done on the first two days that the postal officials are delighted. The new deal throws nine horse-drawn teams out of commission, and if the results of the first few days' operation are continued for a reasonable length of time, the motor truck collection service will be considerably extended. It is understood that the government is paying $3,000 per annum for each truck with its driver

POPE MFG. CO. REPORTS PROGRESS

Hartford, Conn., Oct. 2—The report of the reorganized Pope Manufacturing Company, of this city, shows that during the period from December 24, 1908, to July 31, 1909, the net earnings of the company have been $482,866. Under the heading of assets is listed real estate, equipment, plant and patents totaling $5,194,835. The total assets of the company approximate $6,910,414. Only the factories at Hartford and at Westfield, Mass., have been operated. A new branch of the business, the building of automobile ambulances, patrol wagons and fire equipment, has proved very profitable.

Pole Discoverer Cook Receiving Ovation in Boston

On the occasion of Dr. Cook, the successful Arctic explorer, visiting Boston to deliver his lecture at Symphony Hall, he was driven around in a Thomas car by C. S. Henshaw, manager of the Thomas Boston branch. Another Thomas followed with the reception committee. During the whole of Dr. Cook's week of lecturing he will be driven around in Thomas cars, arrangements having been made to have a car of that make meet him at each stop.

TO STOP JOY-RIDING AND RAKE-OFFS

PHILADELPHIA, Oct. 4—With a view of putting a stop to "joy-riding" and "rake-offs," a number of prominent local garage owners met last week and formed an organization under the title of Philadelphia Garage Association. Stringent by-laws were unanimously adopted, among them being one providing for a fine of $25 for any member who shall pay a commission to a chauffeur, failure to pay which subjects the offending garage to suspension from membership. Another rule provides that upon request a member will furnish to any patron a complete daily record of the movements of his car during the preceding month. An employment bureau, through which the clientele of members of the association will be furnished with competent chauffeurs upon the payment of a small fee, has also been established.

LATEST COLUMBIA SHOWS CLASSY BODY

Among the newer bodies and color schemes none shows more attractive lines than the newest product of the Columbia Motor Car Company, whose big plant at Hartford, Conn., is very busy in a quiet way turning out the rejuvenated Model 29. The latest form which this takes is the short chassis with toy tonneau, double or single rumble. All three of these are interchangeable, as the picture shows. This represents a toy tonneau, but beside it on the ground is placed a single-rumble, which may be substituted for the tonneau in the length of time it takes to tell it. This particular body was done in a light gray, striped a lighter green, and upholstered in dark green. The whole effect is very attractive, as are also all of the other color tones, most of which show a tendency towards gray and the lighter colors.

Latest Columbia is a Nattily Designed Runabout

TIRE OUTPUT WILL TOTAL THIRTY MILLIONS

"The tire output of this year will total nearly $30,000,000," declares H. S. Firestone, one of the best informed authorities on the subject, "and next year's production is expected to run between $45,000,000 and $50,000,000."

The rubber harvest has averaged an annual increase of only about 11 per cent. for several years, which is barely enough under normal conditions to keep pace with general business requirements. It is owing principally to the recent large demand and to local conditions in the rubber districts that fine Para rubber has steadily risen from 67 cents a pound in February, 1908, to the record price of $2.15 which now prevails for immediate delivery. There is very little to be had even at that price.

"Most of the rubber used comes from the Para district, up the Amazon River, where it is harvested wild, and from Ceylon, where it is gathered from extensive plantations. Some rubber comes from Mexico, Africa and parts of South America outside the Para district, but this is of inferior grade and the automobile world will eventually have to look to the rubber plantations to supply a large portion of the extraordinary amount required in the manufacture of high-grade tires."

DETROIT'S BIG LITTLE SHOW

DETROIT, Oct. 4—January 24-29 are the dates selected by the Detroit Auto Dealers' Association for the biggest little show in the country. This year, as last, the show will be held at the Wayne Pavilion, and it is planned to make it even more representative than in the past.

Those who witnessed last year's exhibition will realize that when the association announces its determination to make the forthcoming show bigger and better than ever it will have to go some. Manager E. LeRoy Pelletier last winter evolved a show that was an eyeopener even to New York and Chicago, and in point of beauty had no rival. Just what the dealers have up their sleeves is not disclosed at this time, but something new and novel is promised.

John Gillespie, one of the most active members of the local motoring colony, and well remembered by Glidden tourists and others as secretary of the entertainment committee that made life pleasant for participants in the big A. A. A. tour before leaving Detroit, will act as manager of the show.

STUDEBAKER MANAGERS CONVENE

SOUTH BEND, IND., Oct. 2—Twenty-four Studebaker branch managers spent the past week in their annual convention at this city. A tour of inspection was made through the carriage and wagon factory. This plant covers an area of two square miles and the trip covered a distance of about 24 miles. As it was impossible to make such a journey on foot, a number of Studebaker electric cars were pressed into service for use in the corridors of the buildings. In this way the trip was made in a single afternoon with ample stops for inspection. A trip was also made to Detroit to inspect the plants in which are made the Studebaker-E. M. F. and the Studebaker-Flanders and from there the party went on to Elyria, O., to see the Studebaker-Garford factory. It is said that the combined Studebaker interests will make and sell 40,000 cars during 1910.

LATEST NEWCOMER FROM DETROIT

DETROIT, Oct. 4—The Paige Detroit Motor Car Company has been organized, and it is announced that by December 1 the new car will be on the streets ready for delivery. Fred O. Paige, for some time identified with the Reliance Motor Car Company until its absorption by the General Motors Company, is president and general manager of the new concern; Willis Buhl, vice-president; Gilbert Lee, treasurer, and William B. Cady, secretary.

The company will manufacture runabouts selling for $800, and will introduce several revolutionary features. Chief of these will be a two-cycle three-cylinder motor.

Told in the Progress of the Industry

Oakland Increases Stock—Continuing the policy of the General Motors Company, as illustrated in the recent doubling of the capital stock of the Olds Motor Works, the capital stock of the Oakland Motor Car Company, of Pontiac, Mich., has been increased from $300,000 to $800,000. A question has been raised by the Secretary of State of Michigan as to whether the General Motors Company can legally do business in that state, and an investigation is being made by the Attorney-General. It is doubtful whether the laws permit holding companies to own the stock of Michigan corporations. At any rate it is contended that the state is entitled to a franchise fee from the company.

Needless to say, if this view is upheld it will have a far-reaching influence on future combinations, and this phase of the industry is of growing importance.

Tires in the L. I. Derby—Chevrolet's non-stop record in the Riverhead race was in some measure due to the performance of the Michelin tires with which his car was equipped. The first three cars to finish in the big car race, De Palma's Fiat and Disbrow's and Lund's Rainiers, were also fitted with Michelins. Only two Michelins were changed in the entire race, and those because of punctures caused by horseshoe nails. Ajax tires were used on the Maxwell cars driven by See, Costello and Doorly in the small-car class, finishing first, second and fourth, respectively. All three sets were in excellent condition at the finish, no punctures or other trouble having been reported.

Erie Hammer the One Used—In the description of the equipment of the new addition to the Rambler factory at Kenosha, Wis., in The Automobile of September 23, page 535, the name of the steam drop-forging hammer and its makers, the Erie Foundry Company, of Erie, Pa., was inadvertently omitted. This company, in addition to its extensive line of steam hammers and shearing machinery, traveling grates and stokers, makes a specialty of castings and finished automobile cylinders exceptional in character which are meeting with great demand from the manufacturing trade.

Stepney Now Makes Rims—The American Stepney Spare Wheel Company, of Chicago, is utilizing part of its new plant to turn out in quantities its improved standard clincher rims. These rims are copper-plated and are said to be considerably stronger than the usual type. A large supply is being carried on hand for immediate delivery, both in Chicago and at the New York branch, 1773 Broadway. Samples will be sent to the trade on request.

Osburn Foundries Reorganized—The Osburn Foundry Company, of Detroit, has been reorganized under the name of the Osburn Electric Company, but will continue to manufacture the same line of magnetos, batteries and coils. This move provides a broader plan, larger capitalization and better facilities. The assets of the old company have been included in those of the new, and its liabilities have likewise been assumed.

Change in Forging Company—The Lakeside Forge and Wrench Company, of Springfield, Mass., has acquired the plant of the Springfield Drop Forge Company, and began operations there with a full force of men on September 27. Eugene Childs, formerly connected with the Trimont Mfg. Co., of Roxbury, Mass., will be president and general manager of the company.

Studebaker's Foreign Log-Books—For the benefit of Americans who wish to tour in Europe, the Studebaker Automobile Company is publishing a log-book containing an illustrated description of the extensive trip recently made "on the other side" by Walter Hale. The contents include road maps, distances, and information as to taxes, passports, fees, etc.

Detroit Headquarters for "The Automobile" and "Motor Age"—H. H. Gill, advertising representative of the Automobile and "Motor Age," has opened up commodious Detroit offices in the Majestic building, which, in view of its central location, is the place of call for the fraternity at large when sojourning in Detroit.

Re-Financing of the Berkshire—The Berkshire Motor Car Company, of Pittsfield, Mass., which went into bankruptcy during the panic, has been reorganized with a capital of $120,000, and may locate in Hartford, Conn. John McQuade, the trustee, has been in that city looking over the Pope Mfg. Co.'s tube mill.

K-W Floor Space Doubled—Word comes from Cleveland that the K-W Ignition Company of that city has doubled the floor space of its plant and is preparing to manufacture its magnetos and coils in much larger quantities next season.

Inspection Tour of Studebaker Branch Managers of the Big Factory Plant at South Bend, Ind.

While apparently traveling over roofs, the cars pictured are carrying the Studebaker branch managers on a tour of inspection through the mammoth plant at South Bend, Ind. On this trip, a distance of 24 miles is covered through every floor and over a system of tramways, which run over the roofs and connect the various buildings. The cars are shown on one of the tramways.

IN AND ABOUT THE AGENCIES

New Moon Agencies—The following new agents have been appointed by the Moon Motor Car Company: Motor Sales Company, Washington, D. C.; Moon Car Agency, Tampa, Fla.; City Garage, Springfield, Ill.; Keller & Company, Edwardsville, Ill.; E. H. Wilson, Bartlett, Tex.; Duff & Company, Nebraska City, Neb.; Stearns Automobile Company, Los Angeles, Cal.; T. J. McConnell, Atlanta, Ga.; J. Wills, Des Moines, Ia.; C. L. Baker, Holyrood, Kan.; W. C. Ballard & Company, Oklahoma, Okla.; J. H. Monner, Aurora, Neb.; Hill Storage & Implement Company, Burlington, Vt.; Segerstrom Automobile Company, Minneapolis, Minn.; J. Pumphrey, Memphis, Tenn.; R. T. Jones, Ballinger, Tex.; C. Krumsick, Washington, Mo.

Oldsmobile and Oakland, Pittsburg—The Federal Motor Car Company has been appointed exclusive agent for the Oldsmobile and Oakland in Western Pennsylvania, West Virginia and Maryland, and has taken over the former quarters of the Oldsmobile Company at 5922 Baum street. J. H. McClarren is president of the company and A. M. Brown, manager.

More Hupmobile Agencies—The following sub-agencies for Ohio have been placed by C. Roy Cliugh, manager of the Columbus branch of the Charles Schiear Motor Car Company, State agents: Newark, G. D. Heisy; Springfield, L. E. Bauer; Greenville, Swope Music Company; Dayton, A. H. Pearsen, at the Central Garage.

Studebaker, Brooklyn, N. Y.—The interests of the Studebaker Companies will be looked after in this borough by the Carpenter Motor Vehicle Company, 1239 Fulton street. A number of changes have been made in the building to provide an attractive home for the Studebaker cars.

Hupmobile, Augusta, Ga.—"Ty" Cobb, the star of the Detroit ball team, has often been reported about to enter the automobile business, and this time the report seems justified. He will handle the Hupmobile at 647 Broad street.

Continental Tires, Pittsburg—The Continental Caoutchouc Company announces that its tires and rims will henceforth be handled in Western Pennsylvania by the Jos. Woodwell Company, 203 Wood street, Pittsburg.

Overland and Marion, Oakland, Cal.—Messrs. Tallman and Stephenson are to act as agents for the Overland and Marion cars, as well as for the California-built Sunset, with headquarters at 310 Twelfth street.

Pullman and Keystone, Houston, Tex.—The Imperial Motor Car Company has been organized to hold the Pullman and Keystone agencies in this city, and will locate at Prairie and San Jacinto streets.

Selden, New York City—In the future the Selden car will be handled in the metropolitan district by the Cloud-Marts Company, and a salesroom will be opened at 1871 Broadway.

Chalmers-Detroit, Burlington, Ia.—The local agency will in the future consist of John P. Sheagren and W. B. Hunt, who have also secured the agency for the Hudson runabout.

PERSONAL TRADE MENTION

E. M. West, known in trade circles as former automobile editor of the new York Times, and later as advertising manager of the Harry S. Houpt Company, has taken charge of the New York office of the H. L. Hornberger Advertising Agency, of Philadelphia. He is now located at 2010 Broadway.

Henry Goodman, for a number of years the Eastern traveling representative of the Waverley Company, has engaged with the Buick Motor Company. He will be attached to the commercial department of the New York branch.

C. C. Hildebrand, sales manager of the Stevens-Duryea Company, of Chicopee Falls, Mass., has started on a trip which will take him to the Pacific Coast. He will not return to the East until November.

R. B. Eifer, formerly salesman with the Flint Motor Car Company, of Providence, R. I., is now the Fall River, Mass., representative of Alvan T. Fuller, New England Packard agent.

D. T. Keenan has jointed the Hart-Kraft Motor Company, of York, Pa., manufacturer of commercial vehicles, as salesmanager, his appointment to take effect immediately.

George L. Bixby has entered the service of the Overland Automobile Company, of Indianapolis, as secretary to W. H. Brown, the manager of the Indianapolis factory.

Weldon A. Fosdick is now salesmanager of the Moline Automobile Company of Texas, located at Dallas. He was formerly connected with the Maxwell Company.

J. V. Carr has accepted the position of salesmanager with the Fuller Power Truck Company, of Delphos, O., manufacturer of four-wheel drive trucks.

RECENT INCORPORATIONS

Tate Gas-Electric Motor Vehicle Company, Jersey City, N. J.—Incorporated with a capital stock of $100,000, by J. L. Tate, C. E. Tate and J. L. Tate, Jr., all of Jersey City, to manufacture automobiles, motor boats and aerial machines.

The Leech Automobile Company, Trenton, N. J.—Incorporated with a capital stock of $500,000, by C. A. Bliss, of Toledo, O.; J. P. Le Fevre, Dover, Del., and C. H. Le Fevre, Smyrna, Del., to manufacture automobiles.

De Schaum-Hornell Motor Company, Buffalo, N. Y.—Incorporated with a capital stock of $150,000, by W. A. De Schaum, W. C. Paul, R. H. Lincoln and H. J. Hopkins, to manufacture gasoline motors.

Metzger Motor Car Company, Detroit—Incorporated by W. E. Metzger, B. F. Everitt and W. F. Kelly, with a capital of $500,000, of which $300,000 has been paid in, to manufacture automobiles.

Commercial Car Company, Keyport, N. J.—Incorporated by G. F. Smith, P. and W. Cherry and C. Russell, with a capital of $125,000, to manufaoture automobiles and motor boats.

Croxton-Keeton Motor Company, New York City—Incorporated by H. A. Croxton, J. P. Stoltz and W. D. Grand, with a capital of $60,000, to manufacture and sell automobiles.

Mono Motor Car Company, Elizabeth, N. J.—Incorporated with a capital stock of $300,000, by W. H. Wood, H. T. Eaton and Charles Roberts, to manufacture automobiles.

Warren Motor Car Company, Detroit—Incorporated with a capital stock of $100,000, by Homer Warren, C. R. Wilson and H. C. Walters, to manufacture automobiles.

Clark-Carter Automobile Company, Jackson, Mich.—Incorporated with a capital stock of $100,000, to manufacture automobiles.

Premier Agents, Thirty-two in Number, Representing Every Large City, Being Entertained on Sight-Seeing

GOODRICH COMPANY'S NEW YORK STORE

One of the most admirably equipped buildings for the handling of rubber products, especially tires, has just been finished by the B. F. Goodrich Company, of New York, at 1780-1782 Broadway. The structure is a notable addition to the business buildings of the neighborhood in which it stands, on Broadway next to the corner of Fifty-seventh street, and it has an ell of almost equal size at 225-227 West Fifty-seventh street, There are twelve floors and a basement. The latter is used entirely for the storage of tires. The rear of the ground or street floor is a receiving and shipping room. The front is a large salesroom. which has been very effectively done in mahogany, and green marble is also an element of the finish. It has been chosen for the counter tops and the heavy pillars that support the ceiling.

On the second floor, looking out on Broadway, is the reception room—a considerate provision for the comfort of customers who may be awaiting attention. There are large easy chairs, smoking tables and convenient writing desks. The finish here is fumed oak. A rear room is reserved for the solid tire storage and repairing. Here is a complete wheelwright and forge equipment, so that all tire fitting can be done, as well as the repair work.

The eighth floor has been given over mostly to offices for the manager and salesmen. The rear is a storeroom for the stock of mechanical rubber goods. Above, on the ninth floor, are the general offices for the clerks.

The next floor, for the company's use, is the eleventh—a large stock room for specialties such as druggists', surgeons' and stationers' rubber sundries.

On the top, or twelfth, floor are the most complete automobile tire repair facilities in the United States.

Throughout this building, seemingly, no mechanical device for the ready handling of the heavy stock has been omitted. There are special automobile elevators. One of these has the convenience of a turn-table floor. There is also a general freight lift. In addition, two passenger elevators are provided, and an electric dumbwaiter, adjusted to stop automatically at any floor.

Goodrich's New Metropolitan Home

The exterior of the building is white and green marble, with bronze capitals and decorations for the first two stories. Above this the material is pressed brick with white stone trimmings.

The combination is effective and distinguishes the building as a conspicuous achievement. W. H. Yule is general manager, with H. C. Miller in charge of the automobile tire department.

HAWS WINS RIGHT TO NAME PANHARD

In Part IV, special term of the Supreme Court of New York, Judge McCall has just rendered a very important decision. This was in the case of Geo. A. Haws versus the H. T. Alexander Company, both of New York City. The cause of the suit was the name of an oil, Haws having brought out an oil which he called Panhard. This, as brought out in the trial, was in 1901. In 1907, Alexander also brought out a Panhard oil, and was soon sued by Haws. After much litigation the case was finally settled by Judge McCall's decision, which was to the effect that Haws alone had the right to use this name in connection with lubricating oils. One very important point to the trade at large brought out by this suit is that a car manufacturer has no right to this same car name when applied to some other object or substance. This point was brought out when Judge McCall ruled out the testimony to the effect that Haws had a license from Panhard & Levassor. The judge ruled this testimony out as having no relevancy or effect. The ruling, in part, was:

"While some proof was offered on the part of the defendants to establish their prior use of the name, to say the least about it, it falls far short of the force requisite to give it any convincing power. and I believe the fact to be that the defendant did not use this designation until 1907, some three years after the plaintiff had been serving the trade with 'Panhard oil' and expending their energies and capital to establish it as a foremost factor in the trade. While I admitted the proof of the issuance of a license to defendant by the manufacturers of the Panhard car to use the name 'Panhard,' it has no relevancy to this case, and does not affect the question one way or the other. Judgment must, therefore, be rendered, granting the injunctive relief prayed for, and accounting must be rendered of the sales made by the defendant under the name 'Panhard.' Findings to be submitted."

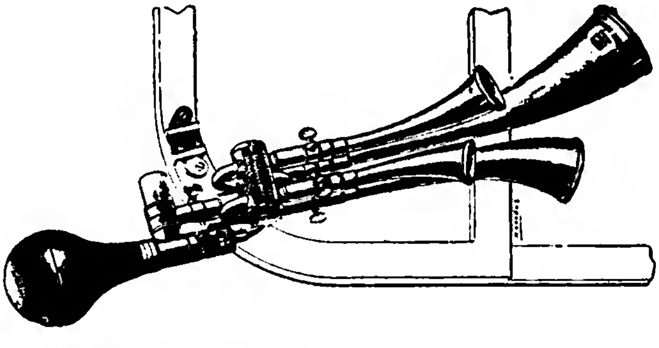
RECENT TRADE PUBLICATIONS

The New Era Gas Engine Company, Dayton, O.—The latest type of motorcycle manufactured by this company is an automobile in every respect except the number of its wheels. The bicycle pedals and saddle have been replaced by a footboard and a comfortable formed seat; the motor is started with a crank, and drives through a two-speed planetary gear. The gears and the brake are controlled by automobile-type push pedals on the footboard. The motor develops 3½ horsepower, its cylinder dimensions being 3¼ and 3½-in. bore and stroke, respectively. Wheels are 28-in. in diameter, with 2½-in. tires, and the wheelbase is 60 in. The merits of the New Era are set forth in a 16-page catalog, illustrated with clear half-tones of the machine, its motor and special features. which in turn are well explained by the text.

Trip to French Lick Springs, Ind., Upon the Occasion of the Annual Agents' Convention at Indianapolis

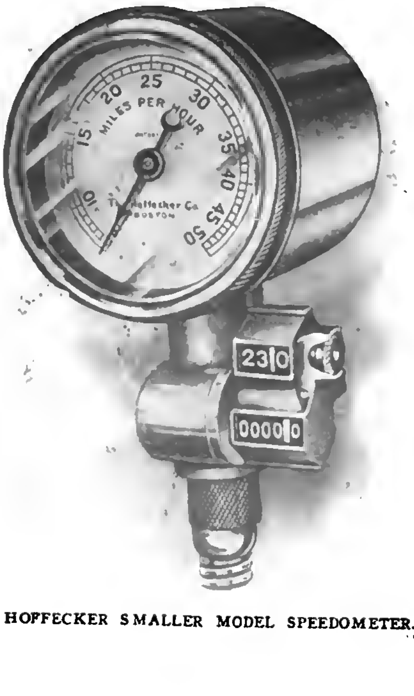
Information for Auto Users

The Musical "Testophone"—This French device is one of the latest ideas in the signaling line, and has the merit that, unlike most of the recent products in this line, its sound is really pleasing, and does not cause shivers to run up the spine of the inoffensive pedestrian. The Motor Car Equipment Company, of 55 Warren street, New York, which sells it in this country, says that it has made more friends in the short time it has been on the market here than any other device, and the friends are not numbered among the automobilists alone. Not only is it an effective warning instrument, but its bugle calls are novel and pleasing. It resembles an ordinary bulb horn in its operation, but has four reeds, each with its separate trumpet. Each time the bulb is pressed a piston arrangement actuates a ratchet wheel at the base of the horn, revolving a valve which directs the air to the various tubes in turn. The effect of pressing the bulb lightly a number of times in rapid succession is to give a fanfare closely resembling a bugle call, as the different notes of the group are sounded in sequence and sometimes in combination. The combinations can be controlled and varied at will by adjusting the valve. The horn is 26 inches in length and is finished in brass.



THE LATEST FRENCH MUSICAL HORN IS CALLED "TESTOPHONE"

1910 Hoffecker Speedometer—Still using for its watchword the phrase "The Steady Hand," the Hoffecker Company, of Boston, has brought out 1910 models of its speedometers, differing from former designs only in detail refinement. All the three styles use identically the same speed-indicating movement, which is that always known under this name. It is of the centrifugal, flying-ball governor type, in which the indicating hand is actuated through an irreversible device which prevents any movement save those caused by variations in the speed of the car. The smallest model has a 3-inch dial, graduated to 50 miles, and to save expense a Veeder odometer is used, carried beneath the dial; it registers to 100 and 10,000 miles respectively on the trip and season indicators. A larger and more expensive model has a 3 1-2-inch dial, graduated to 60 miles, and the odometer, of Hoffecker construction, is incorporated in the body of the instrument. On this the trip mileage is registered on a circular dial concentric with that indicating the speed, by means of a moving hand; the season register shows figures in the usual manner. This large instrument is also made in combination with a Chelsea clock, in a circular case similar in size and shape to that of the speedometer, and is provided with an electric light between the two dials.



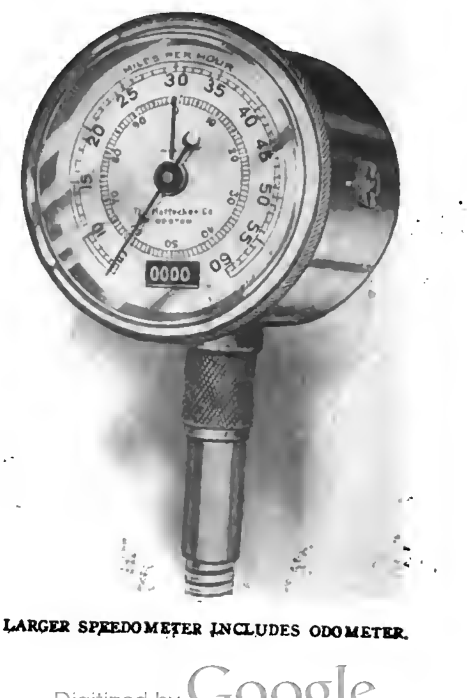
HOFFECKER SMALLER MODEL SPEEDOMETER.

Ronson Pocket Wrench—"Nine wrenches carried in the vest pocket" summarizes this clever device. With a length of 6 inches and a weight of 8 ounces one may have nine wrenches, ranging in size from 3-16 to 13-16 inch, a perfect substitute for a set which ordinarily would weigh 5 pounds and take up half a tool-box. The "Ronson" consists of four thin plates of steel, each, with jaws at either end, slotted in the middle and clamped together by a square bolt passing through the slot. By loosening a wingnut any desired member can be slid out into working position, leaving the other members to form a handle and give greater leverage. As the members must be very thin, they are made of plate steel, carefully heat-tempered. The center bolt and wingnut are drop-forged. The thinness of the members is in itself claimed to be an advantage, as it enables the wrench to be used in places where an ordinary type of wrench could not be applied. The finish is

RONSON VEST POCKET WRENCH.

nickel. Cryder & Company, Park avenue and Sixty-third street, New York City, hold the exclusive selling agency.

Carborundum Grinding Compound—Formerly carborundum powder has only been available in the dry state, and when used for grinding in valves it has been necessary to mix it with oil or grease. Naturally, the mixture was often done by guesswork, and the results were not always what may have been desired or expected. To obviate this objection the Carborundum Company, of Niagara Falls, N. Y., which makes carborundum powder, grinding wheels, etc., has brought out a ready-to-use valve grinding compound, which consists of a suitable grade of carborundum powder mixed in the proper proportion with a high-grade grease. The compound is put up in a handy little case, which contains two collapsible tubes, one of coarse compound and one of the finer grade, and also a package of carborundum cloth strips for cleaning vibrator and contact points, and a book of carborundum cloth for general use. For those who have acquired some degree of skill in the mixing process and wish to mix their own compound, another kit is offered, containing two quarter-pound cans of dry powder, coarse and fine, as well as the cloth strips and book. It is claimed that the work can be done with this material quicker than with glass or emery, and that a better valve seat is secured.



LARGER SPEEDOMETER INCLUDES ODOMETER.

Vol. XXI New York—Thursday, October 14, 1909—Chicago No. 16

THE AUTOMOBILE

Robertson Again Wins Fairmount Race

Robertson—Trophy—Smile

OFFICIAL ORDER OF THE FINISHING QUINTETTE			
Pos.	Car	Driver	Time
1	Simplex, 90 h. p.	Robertson	3:38:58-8-10
2	Chalmers-Detroit, 40 h. p.	Dingley	3:44:20
3	Apperson, 50 h. p.	Harding	3:52:17-7-10
4	Chadwick, 60 h. p.	Parkin	3:55:31-2-10
5	Isotta, 40 h. p.	Strang	3:56:54-4-10

PHILADELPHIA, Oct. 9—George Robertson is thoroughly at home in Fairmount Park. To-day, driving a 90-horsepower Simplex, he scored from a representative field in the 200-mile stock chassis race. A year ago, with a 40-horsepower Locomobile, the same intrepid driver appropriated honors which he appreciates with a characteristic modesty that adds to his widespread popularity. Robertson has become the American Nazzaro, and it would be most interesting if he were to meet the coolheaded Italian in a motor-driven battle for the world's championship. Such a race would be worth the watching.

True it is that in to-day's race Robertson had a Simplex speed craft possessed of twice the power of Dingley's Chalmers-Detroit, which finished second, but the fact remains that the pilot of the larger car did his work in a brilliantly capable manner.

Some five minutes behind Dingley came Harding with a well-driven Apperson "Jack Rabbit," while the Chadwick, with the younger and elder Parkin aboard, had a rattling good battle with Strang—once more on an Isotta—for fourth place, the six-cylinder from Pottstown proving the victor.

In addition to the honors which go along with an impressive win under such favorable conditions, Robertson annexed $2,500 in gold and the $1,000 MacDonald and Campbell trophy. Dingley captured $1,250 in gold and a gold chronometer for the most consistent work. Along with third place Harding gathered in $750, while the plucky work of "Joe" Parkin against a past master in the art of driving brought him in $500 in the yellow metal. This youngster was one of the race's surprises.

Robertson's victory is a great personal triumph, inasmuch as the Fairmount Park eight-mile circuit is what might be termed a "driver's course." There are no long straightaways on which a big, powerful car can be opened wide and thus mow down its less powerful competitors. Every car in to-day's race was

90-Horsepower Simplex (Robertson) That Won the Contest Had Speed in Plenty capable of a mile-a-minute speed or better, but such a clip, if maintained over the sinuosities of the Park roads that composed the course, would soon bring to grief the driver who attempted it. Robertson averaged about 55 miles an hour, but withal nursed his car so carefully that he was compelled to stop but once to remedy minor trouble and once for supplies. The fact that he guided a Locomobile to victory over the same course last year would seem to bear out the claim that it was a Robertson rather than a Simplex victory.

Philadelphia and the Quaker City Motor Club to-day set a mark in big race management which other promoters may aim to approach; they can hardly excel it. Eighteen hundred policemen, 120 flagmen and umpires, a big corps of doctors and nurses with all the paraphernalia of their craft, and miles and miles of rope made for the public safety. The whole problem of course-guarding was directly under the eye of Mayor Reyburn and the Department of Public Safety, with Superintendent of Police Taylor doing the action stunt. That they succeeded in their task was manifest, for the accidents in that mighty crowd, where accidents were to he expected, were few and far between, and even those that did occur were of a minor variety.

The only accident to a racing man came in the 8th lap when American, No. 12, Hayes, driver, was negotiating the combination S-hairpin at Sweet Brier Mansion. The car skidded to the right and then to the left, landing heavily against one of the ubiquitous telephone poles without which no course seems complete. Hayes shut off and held to the wheel, managing to stay with the car when the crash came. Mechanician A. H. Johnson went ahead when the car stopped and landed on his head and shoulders in the grass. He was merely stunned, however, and in a couple of minutes, with the aid of the Red Cross artists who were on the scene in a jiffy, he and Hayes were walking cross-country to the main stand.

Malin Leinau, driving Acme, No. 7, missed serious trouble at the same point by quick work and a little luck. His speed carried him so far to the side of the road that the car mounted the gently shelving bank, and ran on the grass for fifty yards, passing between the scattered trees and reaching the road some distance below. On a later lap the Acme shed a tire at the foot of the same slope, and had to stop directly in the path of the others while the crew fitted another to the wheel.

The Selden, No. 23, broke a wheel on the same S-hairpin on the first lap and lost over half an hour.

The Acme furnished a sensation on the 12th lap, when the right rear tire came off directly in front of the upper end of the long grand stand. The tire flew 30 feet into the air and in its descent struck a small boy who was watching the run from one of the pits in front of the stand. He was merely stunned, but was carried off by one of the official Red Cross cars in a jiffy.

It was a day for the four-cylinder car and one for the light-weight and small-horsepower machine. The "40" Chalmers, runner-up to the "90" Simplex, had scarcely half the latter's piston displacement, and it took a 710-cubic inch Chadwick to beat the 490-cubic inch Isotta by a minute. Both these cars also made wonderful average laps, the Isotta not varying over 29 seconds, while the Chalmers' greatest variation, barring the first two laps, was 50 seconds. Only fourth place was taken by a "six"; first, second, third and fifth went to four-cylinder machines. The following were the four and six-cylinder machines entered:

No.	Four-Cylinder	H.P.	No.	Six-Cylinder	H.P.
2	Simplex	90	2	Thomas	70
2	Chalmers-Detroit	40	2	Chadwick	90
2	American	60	1	Acme	60
2	Buick	30	1	Palmer & Singer	60
1	Benz	60	1	Alco	60
1	Apperson	60	2	Welch	70
1	Columbia	32	1	Lozier	50
1	Isotta	45			
1	Selden	36			
13			10		

The average speed of the first five cars was higher than that of last year's winner. No. 4 Simplex averaged 55.4 miles per hour; No. 5 Chalmers, 54.2; No. 8 Apperson, 52.2; No. 18 Chadwick, 51.4; No. 17 Isotta, 51.3. The Locomobile last year did 50.1.

Not only were the average speeds very much greater, but the lap speed of some of the cars was nothing short of wonderful, if the timing was correct. (Needless to say, the method used did not impress old timers as very satisfactory.) Zengle in the Chadwick made a lap in 7:41, or at a rate of 63.3 miles per hour, and with it came $100 in gold. Next came the big Simplex with 62.9 miles per hour. Following these closely came Dingley with a lap at 62.3. The fourth best was Betz with the other Simplex, 61.5.

This is only part of the story, however, for although the first two cars, Nos. 16 and 4, had the largest motors in the race, No. 5 had one of the smallest. The piston displacements were:

No.	Car	Driver	Cu. In.	Finish
16	Chadwick	Zengle	710	Out
4	Simplex	Robertson	672	First
5	Chalmers	Dingley	373	Second
1	Simplex	Betz	672	Out
8	Apperson	Harding	596	Third
18	Chadwick	Parkin	710	Fourth
17	Isotta	Strang	490	Fifth

This shows that the Chalmers, with 55 per cent. the displacement of the Simplex, was able to almost hold its own with the larger car. In addition, because of its smaller motor, it did not have to stop for fuel during the race. Because of its light weight it was not necessary to stop for tires—in fact, Dingley never made a stop during the race. The consistency prize, a gold watch, offered by the Autolight Company, went to this combination of man and machine. Robertson only stopped once, on the fourteenth lap, to replenish his fuel supply and change tires. There was some talk of protesting the Simplex on the ground that it was not stock. Later it was given out that the Chalmers-Detroit had decided not to force the issue.

To Strang and the Isotta should go the credit of making the most consistent run of all the cars. At no time during the race, except when he stopped for fuel on the eighteenth lap, did the Isotta's time vary over 29 seconds. His slowest lap was 9:31; his fastest 9:02. In all races in which Strang has piloted an Isotta car he has made just this consistent running.

The first five cars were equipped with Michelin tires. Robertson and Harding made but one change, and that when they stopped for fuel supplies.

HOW THE RACE WAS FOUGHT BY LAPS

Lap 1—It was evident that there was to be no waiting game played, for all the favorites let their cars out to the limit from the jump—Robertson in the Simplex, Chevrolet in the Buick, Drach in the American, and Zengle in the Chadwick, all doing the lap under 9 minutes—in 8.33, 8.40, 8.44 and 8.50 respectively—with Dingley's Chalmers third and William's Palmer-Singer fifth and sixth respectively. Selden, No. 23, threw a tire at Sweet Brier Hill, less than a mile from the start, and lost 35 minutes. Burman's Buick, No. 9, was not working right, and he finished the lap among the tail-enders. Haupt in the Thomas, No. 6, Leinau in Acme, No. 7, and Harding in the Apperson, No. 8, also had trouble with tires on the initial round, and lost valuable ground. Seymour, on the back stretch, near Neill Drive serpentine, broke his water pump and dropped out then and there, failing to complete first lap.

Lap 2—Chevrolet jumped his Buick into the lead, with 39 seconds advantage over Robertson, who was sharing third place with Drach in the American, and 32 seconds ahead of Zengle in the Chadwick, who had crawled up into second place. Reports of continued tire trouble came flashing in from Benz, No. 3, Willie Haupt's Chadwick and Leinau's Acme, the trouble occurring in each instance far from the pits, and resulting in additional delay. Dingley was still in fifth place, but by a closer margin, and Parkin has brought his Chadwick up into sixth position, displacing Wallace's Palmer-Singer, which dropped a notch.

Lap 3 saw Chevrolet still in the lead, but by the small margin of three seconds over Robertson, who had an advantage over Drach of 46 seconds. Zengle dropped back to fourth position, eight seconds behind Drach, with Dingley still fifth and his team-mate, Lorimer, in Chalmers-Detroit, No. 19, coming up rapidly from 9th place to 6th. Strang in Isotta, No. 17, first began to show prominently on this round, coming up from 10th to 7th position, and trailing the Chalmers pair closely. The Quaker brewers, Bergdoll and Betz, in the Thomas and Simplex respectively, were having a battle all to themselves, occupying 8th and 9th positions, and being separated by a margin of but five seconds. The former's brother, Erwin, in the Welch, No. 20, failed to register the third lap, having been reported in trouble with his engine on the Neill Drive; he later retired. Coffey's Columbia, No. 14, also developed a loose rear construction, and also withdrew.

Lap 4—Robertson came back to his own on this round, Chevrolet's engine misbehaving sufficiently long to relegate him to 15th place, while Drach and Dingley moved up into 2d and 3d places respectively, but with a margin of nearly 1½ and 3 minutes separating them from the leader, thanks to "Robby's" record 7.44 in the previous round. Amateur Betz, in Simplex, No. 1, crawled up into 4th place, the local man's effort being greeted with cheers.

kept grinding out laps that averaged around 8.35, a short stop in the 11th round, when Zengle came within 14 seconds of him, being followed on the 13th with a thrilling 7.31, which increased his margin of lead by over a minute. In the unlucky 13th round Zengle also opened 'er up and set the stands rocking with a 7.31 circuit; but he must have pushed matters too strenuously, for it was three-quarters of an hour before he reappeared at the tape, magneto trouble developing and delaying him continuously.

During this period Dingley kept ding-donging along at a most beautifully even pace, without a stop for anything, supplies and tires seeming apparently to be unheard-of things in the Dingley lexicon. The margin of time separating him from the leaders seldom varied more than a minute, and the Chalmers kept on in the "even tenor," etc., in a manner that boded ill for falterers.

The plucky driving of Amateur Betz during this period brought him a big hand every time he sent his big yellow Simplex past the stands. He tore off a 7.54 on the 11th round, just to show what he could do. At the end of the 13th round he was a trifle over 7 minutes behind Robertson, going like an electric fan. Strang kept his Isotta within striking distance, and if anything happened it was evident that he would have to be reckoned with.

Dingley's 40-Horsepower Chalmers-Detroit Which Finished a Convincing Second

Strang also improved his position, climbing to 5th place, Zengle dropping to 7th and letting Bergdoll, another local favorite, in ahead of him. Engine trouble was reported as the cause of Zengle's slow-down. Parkin, still another Quaker favorite, who had dropped to 11th on the previous round, moved up to 9th place, right behind Hayes in the American Roadster, who had also improved his position from 12th to 8th place. Haupt's Thomas, No. 6, was reported down and out with engine trouble.

Lap 5 saw Robertson still in the lead, but with Zengle, by virtue of a phenomenal round in 7.40, flashing into the place, with but a trifle over a minute separating him from the leader. Dingley was still third, by a similar margin, while Brewer Betz was ousted from his hold on 4th place by Strang, but by the margin of but one brief second. Bergdoll still occupied 6th position, with Drach, who had to stop at the pit, in 7th place as a result of the five-minute lay-over. Chalmers-Detroit, No. 19, was reported at the filter plant with a broken frame, and was later announced as withdrawn. The Parker Chadwick nosed out the American Roadster, No. 12, for 8th position, the latter leading Harding's Apperson by exactly one minute.

Lap 6—There were no changes in the relative positions of the three leaders, although Zengle had gained 24 seconds on Robertson during the round, with Dingley 2.01 behind the Chadwick. Betz regained fourth place from Strang and led him by 33 seconds at the wire, with Bergdoll's Thomas, Drach's American and Parkin's Chadwick retaining their respective positions.

Laps 7 to 13—For seven laps the positions of the leading quintet remained unchanged. With the regularity of clockwork Robertson

During these seven laps the Parkin Chadwick, Harding's Apperson and the Drach American were having a triangular battle for 6th, 7th and 8th places, the completion of the 13th lap showing them placed in the order named. On the 7th lap Hayes' American, No. 12, was eliminated by a telephone pole into which it skidded on the back stretch, breaking both front wheels and otherwise damaging the car. The following lap witnessed the departure of Leinau's Acme, after a series of disheartening delays due to engine trouble. The same cause was announced as being responsible for the disappearance of Chevrolet's Buick from the course in the 12th lap.

Laps 14 and 15—With Zengle's troubles in the 14th round came a move up for Dingley and Betz, this pair dropping into 2d and 3d places, about 6 and 8 minutes, respectively, behind Robertson. Parkin jumped ahead of Strang just here, and it was a peculiar coincidence that throughout the race, almost from the start, these two were within striking distance of each other, the margin separating them rarely being much more than a minute, except on those occasions when one or the other stopped for supplies. Both cars ran most consistently. Apperson moved up into 6th place on the 14th round and Wallace, in the Palmer-Singer, who had been going sweetly, swung in back of him on the 15th circuit.

Laps 16, 17 and 18—Nothing now apparently being able to dislodge Robertson and Dingley from their positions except serious trouble of some kind, interest in the race was centered in the struggle for 3d place between Harding, Parkin and Strang. The latter looked good to the crowd when he finished the 16th circuit in

Pressmen and Officials Found Working Conditions Somewhat Difficult in the Muchly Crowded Stand

the coveted position and retained his advantage in the next two rounds; but it was evident that the slightest delay for any of the trio would put the others ahead of him, and so it proved. At the end of the 16th round Zengle, whose plucky fight with the leader had won him hosts of sympathizers, finally withdrew his Chadwick, a broken water connection being the last straw. The 18th circuit also witnessed the withdrawal of the last hope of the Buick contingent, Burman's long delay in the 8th round having put him so far in the rear that it was evident that he hadn't a ghost of a chance. This left but nine cars in the race.

Laps 19, 20 and 21—Robertson and Dingley during this period opened still wider the gap separating them from the others, although neither of them took any chance which might dislodge him from his position, Robertson averaging about 8.40 and Dingley around 8.50, and playing 'em safe at all times. Harding and Parkin pried Strang out of his place in the 19th, but the Chadwick man was in turn dislodged by the Isotta on the 20th circuit, which advantage was retained through the next round, although Strang could not make up any of the nearly three minutes or more by which Harding led him at the end of the 19th. Betz's Simplex was taken out of the race at the conclusion of the 20th round for no apparent reason, for the car was moving sweetly.

Laps 22 to 25—At the end of the 22d circuit Joe Parkin dislodged Strang from 4th position, which was being fought for savagely, for it meant $500 in gold to the driver who landed it. The Chadwick man led by but 24 seconds, but in each succeeding lap to the end of the race he added a little to his lead until at the flag he had nearly a minute and a half on the Isotta. Robertson, Dingley and Harding were too far ahead for Parkin to care to do anything more than hold his own, and the race finished with the positions unchanged in the last four laps. When the crowd finally overflowed the track, Drach's American, No. 2; Howard's Benz, No. 3; Wallace's Palmer-Singer, No. 10, and Youngs' Selden, No. 23, were also pegging away, the latter having finished its 17th lap, the Benz its 21st, the American its 20th and the Palmer-Singer its 24th

21	Welch Hall	Did not start.																									

NOTE—Comparing the winner's time and average with the time and average of the same man, winner last year, although driving a different make of car, gives some idea of the progress made in the last year by the various drivers. Just a year ago, Robertson, driving a Locomobile "40," went the distance, then 195 miles, in the time of 4 hours, 2 min. 30 sec., which was then considered very good. This averages to 48.27 miles per hour as compared with Robertson's time this year, which works out 55.9 miles per hour. The whole advantage of 7.63 miles per hour average cannot be ascribed to improvement in construction, as the past has been a year in which the majority of constructors have "stood pat." So, too, with the fastest lap. Last year, Seymour, driving a Lozier, completed his tenth circuit of the 7.8 miles course in 8:32. This year Zengle, at the wheel of a Chadwick, carried off the honors with 7:41 for the 8.1 miles. The assumption almost forces itself upon one giving this thought that the drivers are much faster than other and previous years.

Harding's Handling of the 60-H.P. Apperson Gave the "Jack Rabbit" Third Place

Parkin, Junior, and Parkin, Senior, Capably Piloted the Big Chadwick "Six"

Strang Looked Familiar at the Wheel of the Isotta, and Finished Fifth

SOME RACE GOSSIP

Robertson's one stop at the end of the 13th lap, gave the stands an opportunity to witness action. Robertson was not fairly out of his seat before the Simplexites were all over the car. There was system in the apparent confusion, though, and "Robby" was sent on his way with an encouraging cheer echoing behind him. But the "real goods" in quick action was afforded by the Appersonians, whose pit was almost directly opposite the press stand. Harding, for one reason or another, seemed to stop more often than any of the real contenders. At one stop a new tire was put on and tanks filled in a trifle over one minute.

No. 21, the Welch car that was to have been driven by Al. Hall, did not start, as Hall, who had been arrested earlier in the week for disregarding the signals of the "coppers" and assault on an officer, was disqualified by the contest committee of the Quaker City Motor Club for failure to live up to the practice rules. His $500 entrance fee was returned, and he and his pretty wife, who is the sister of the Bergdoll boys, who drove No. 15 Thomas and No. 20 Welch, and for whom Hall was formerly chauffeur, witnessed the race from the grand stand.

That Job of Starting — Thursday night previous to the race a movement was started by some one among the drivers to depose G. Hilton Gantert from the starter's position on the grounds of inexperience and trade alliances. A "round-robin" was circulated among the drivers, pretty generally signed, and presented to the race committee. As Mr. Gantert is the Q. C. M. C.'s official starter the club refused to impugn his integrity, especially in view of the fact that no representative of the cars he handles was in the race. "Wag," however, served as associate referee.

A big smoker in the huge banquet hall of the Hotel Walton wound up the festivities, at which Mayor Reyburn and all the celebrities were present, including the winning drivers, who were after their plunder. The possible filing of a protest by the Chalmers - Detroit people against the Simplex necessitated the calling off of the distribution, which was to have been one feature of the symposium. The prizes will be given out Thursday night at Keith's Theater, providing there is nothing further turns up to interfere with plans of the management.

Among the out-of-town automobilists who toured from New York to the race was a large contingent from J. M. Quinby & Company, which has recently taken over the Isotta Import Company of New York. The party came, hoping to see Louis Strang celebrate the return to his first love with a victory not unlike the four successive ones of a year ago. In the Quinby party were: President W. W. Ogden, Vice-President Emerson Brooks, Sales Manager Rockett, Claude Hamilton and Charles G. Percival, publicity manager.

WHY SOME CARS DIDN'T PERFORM BETTER

No. 9 Buick stopped at the pits on the second lap to change spark plugs and repair a badly leaking radiator. Large quantities of flaxseed were poured into the radiator in the vain endeavor to stop the leakage. Finally Burman withdrew on this account, it being impossible for him to continue in the race and make any kind of a showing.

Both Willie Haupt, driving No. 6 Thomas, and Chevrolet, driving the Hoodoo No. 13 Buick, broke inlet valves. Haupt replaced his, but Chevrolet had to drop out, as the broken valve punched a hole in the cylinder.

Bergdoll's No. 15 Thomas had such a chronic case of overheating that he finally had to withdraw, this being all that could be determined as to his failure.

Drach, driving an American bearing the same number as at Lowell, No. 2, while making good time for the first few laps, finally had mechanical difficulties which put him out of the race. His first stop was to replace a rear auxiliary air valve. This was followed by the loosening of his auxiliary gasoline tank. The feed pipe unions to the carbureter cracked because of the displaced tank and Drach had considerable difficulty in bringing the car to the pits. After another unsuccessful attempt to fix up the feed pipe the car was withdrawn.

The other American, driven by Hayes, met with disaster at Sweet Brier hill. Hayes stated that first one and then the other rear tire gave way when he set his brakes. The reaction threw the car into the ditch. As it was, Hayes experienced great difficulty to keep from hitting the telephone pole head-on.

This Photograph Was Taken Just as No. 12 American, E. O. Hayes Driving, Punctured and Swung Into a Telephone Pole

No. 10 Palmer & Singer made a good showing, considering that Wallace had to drive the major portion of the race with a broken universal joint.

No. 3 Benz broke an exhaust valve on the third lap and stopped at the pits to replace it. It continued in the race after making the replacement, although hopelessly behind.

The Acme was very unfortunate, having almost no mechanical trouble, but its slow speed was due to continuous tire trouble. The rims would constantly become loose, and the difficulty was finally found to be the use of 4 1-2-inch tubes in 5-inch covers.

Coffey, driving No. 14 Columbia, gave the reason for his accident. Parkin, Senior, also verified the tale. The big Chadwick made a bad skid when turning into City Line avenue, and Coffey, in order to avoid crashing into the Chadwick, tried to go outside between a tree and the car. His rear axle struck the tree and simultaneously his front wheels struck the right rear wheel of Parkin's car. The Columbia's rear axle was torn from the spring clips, so violent was the impact. On the other hand, Parkin's rear wheel was badly loosened up, but by running the risk and doggedly pushing the car along he finished fourth, ahead of the Isotta, which did not stop except for fuel.

Betz, the young amateur driver, after having third place well in hand with No. 1 Simplex on the sixteenth lap, was forced to withdraw on account of a broken pump and overheated motor.

Zengle, with the big Chadwick, which made the fastest time, literally shook his water pipes loose. The pipes on top of the cylinders were leaking badly, and finally, it was stated, his water-pump drain plug opened. The motor ran hot, and it was reported Zengle went down to the Schuylkill River to get water to replenish the empty motor. After this, however, he never was a factor in the race. At the time of this accident he was running second.

No. 22 Lozier was reported to have broken a pump shaft on the first round. Another equally definite rumor was that the after main crankshaft ball-bearing rod broke.

No. 19 Chalmers-Detroit on the fourth lap broke its frame and, of course, retired.

Perhaps the most exasperating incident to happen during the ray was to Harry Grant's No. 11 Alco. As he drew up to the grand stand preparatory to the start, the brazing on his steering column gave way, allowing the wheel to turn independent of the worm and rendering steering impossible.

VANDERBILT RACE PREPARATIONS ARE IN FULL SWING

RUNNING of the Vanderbilt Cup race this year was finally assured when the Board of Supervisors of Nassau County, Monday last, granted permission to use county roads to complete the course. The race is now positively scheduled for October 30.

The course is 12.64 miles long, including, in addition to 5.15 miles of the Long Island Motor Parkway, which is private property, the Massapequa road, the old Country road and the old Westbury road. According to the conditions imposed, the race must be run between 5 a. m. and 5 p. m., October 30, and the contestants are granted permission to use the roads for practice between 5 a. m. and 8 a. m. after October 20.

Further conditions are that the Motor Cups Holding Company, which is promoting the race, must sprinkle the Massapequa road with oil, repair and make safe the old Country road, and must guard and police the roads during practice and on the day of the race. A bond of $100,000 must be deposited to in-

A Lodge Entrance to the Long Island Motor Parkway

demnify the County Supervisors and Sheriff against any damage suits, and the sum of $500 must be deposited to put the roads in condition after the race. It is also provided that if any of the entrants are convicted of violating the speed laws outside of practice hours they and their machines are to be disqualified.

The Motor Cups Holding Association opened a bureau of information this week in room 212 of the Long Acre building, 1493 Broadway, New York City, on the northwest corner of Forty-third street. This office will be open daily from 9 a. m. to midnight, and on Sundays between 2 and 7 p. m. The association has prepared diagrams of the stand, boxes and parking spaces, and the sale of seats has begun. Several hundred applications for seats and boxes are already on file. Prospective applicants are urged to write or call as soon as possible, as it seems almost certain that the demand will exceed the supply.

The course promises an unusually fast race, and also a spectacular one. It will be noticed that the length of the circuit has almost been cut in half. This was done because it was found, from experience at Lowell, Fairmount Park, and elsewhere, that the spectators enjoy a race on a short course more than on a longer course, as the cars pass more frequently. There are no hills and no bad turns on the new course, and the few turns which do exist will have a four-foot bank, carried well around in the straight. The turns on the Parkway, of course, are banked in the most scientific manner. Expert drivers figure that the time should at least equal that made at Riverhead in the Long Island Derby.

Ample time for practice will be allowed the drivers, as they can let their machines out to full speed on the course for ten days before the race. This is not only giving more days of practice than was ever allowed before, but the limits of 5 to 8 a. m. give a longer time each day. The offer of practice should induce manufacturers to make early entries, as the more trials the drivers have the better, of course, will be their chances in the race. It should be noted that the course is open for practice to contestants only. No permission has been granted for private owners to use it other than in the ordinary way and at their own risk in practice hours.

Anderson Brothers, of Mineola, already have a large force of men at work widening the county roads, clearing out the gutters, filling in holes and rolling and oiling the roads. As in previous Vanderbilt races, a complete telephone system will be installed. At each point at which communication is likely to be necessary a station will be established and connected with the official stand by a direct private wire.

No official announcement of the entries can be made yet, as the entry blanks were only issued a few days ago. Enough favorable responses have been received, however, to indicate that at least thirty-five cars will start. The throwing of the race open to stock cars has proved a great incentitve to the manufacturers. Among those who have promised to compete are the Chalmers-Detroit Motor Company, with four cars; the Maxwell-Briscoe Motor Company, with three; the National Motor Vehicle Company, the Buick Motor Company, the Simplex Automobile Company, Marmon & Nordyke Company, the Dayton Motor Car Company, the Knox Automobile Company and the Rainier Motor Company, all with two cars each. There is a possibility of two Benz cars being entered if they arrive from Germany in time. In addition to those who will enter teams, Renault, Moon, Fiat, Isotta, Apperson, Columbia, Allen-Kingston, Alco, Mercedes, Sharp-Arrow, Cameron and Matheson will be represented by at least one car each.

Many familiar names will be found missing from the revised course. From the starting point opposite the grandstand, the route runs east along the Parkway for about two miles; the cars then turn north on a specially constructed cut-off to the Massapequa road, which leads to the outskirts of Hicksville. From here the cars turn west on the old Country road to Westbury, thence south to the Parkway at Meadowbrook Lodge.

Hudson "20" Tries Straightaway with No Speed Limit

FOR AND ABOUT THOSE WHO COMPETE

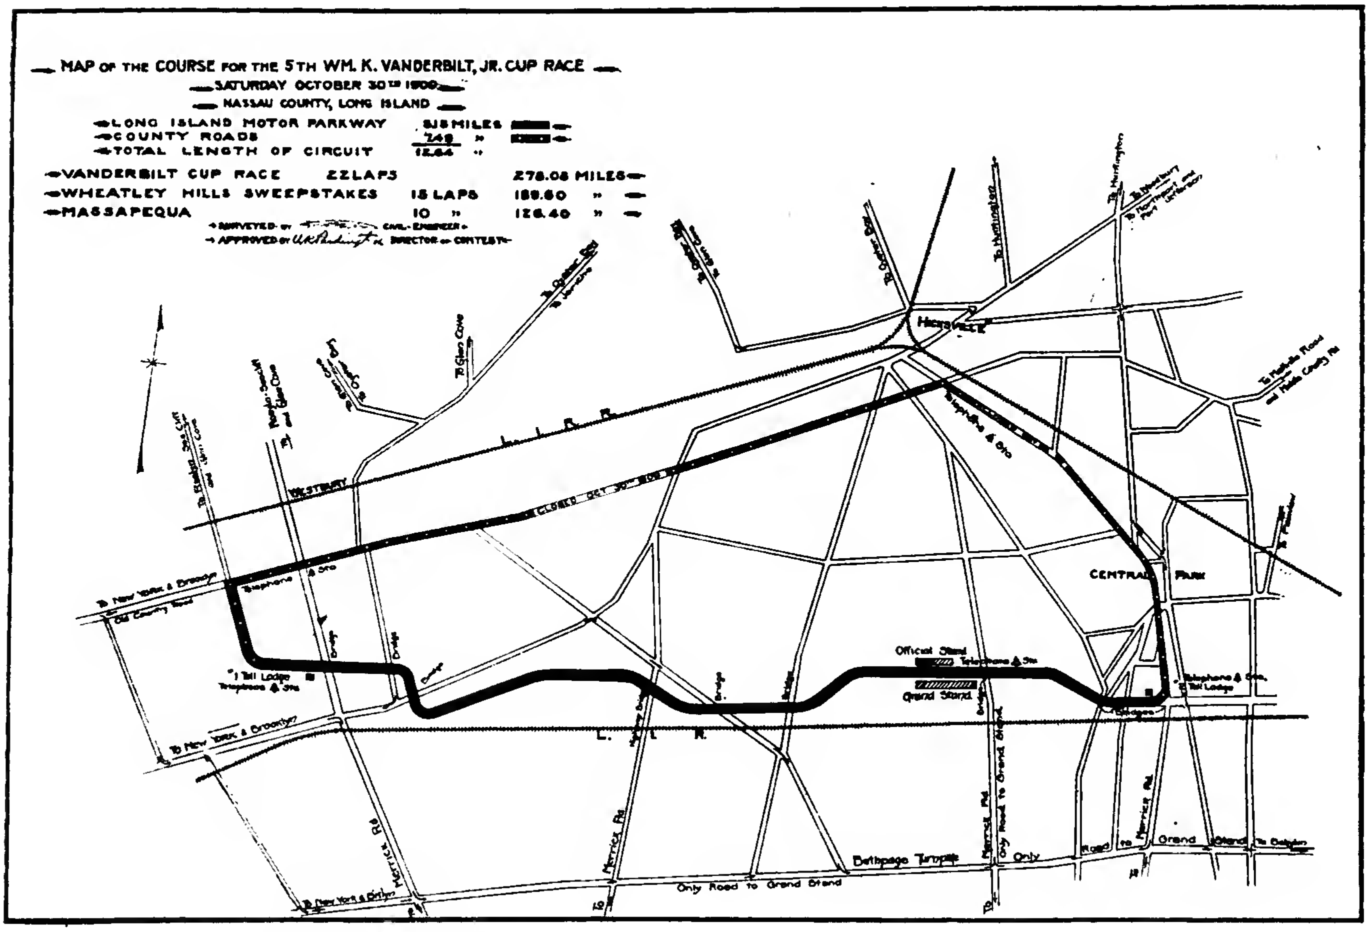
Ralph De Palma Injured at Danbury—The Vanderbilt lost one of its most promising candidates last Saturday when Ralph De Palma, the winner of the Long Island Derby, was spilled from his car on the Danbury, Conn., race-track. The accident happened during the last lap of a five-mile free-for-all, which was contested by De Palma, driving his Fiat "Cyclone," Brown with another Fiat, and Wagner with a Columbia. De Palma had been having trouble with his machine, but overcame it and started after the others. He passed Brown and was overhauling Wagner, when a rear tire burst, causing the machine to crash through the infield fence and turn turtle. De Palma was thrown some twenty feet, landing on his side. He suffered a compound fracture of the left upper leg, and although out of danger, there is no possibility of his taking part in the Vanderbilt.

Race Meet in Lone Star State—The San Antonio Automobile Club is promoting a series of races to be held on the last four days of the International Fair, November 14 to 17, at San Antonio, Tex. Entry blanks have been sent out, and, in view of the attractions offered, should meet with a favorable response. A special automobile track is being constructed, which, although only three-quarters of a mile in length, is of ample width and has well-banked turns. Safety is provided for by a sloping wall of loose earth taking the place of the outer fence, which, in the event of a racer becoming uncontrollable, will bring it to a gradual stop. The program for the first day calls for five races, at distances of from five to 25 miles, for cars classified by price limits. On the second day will be held four races distinguished by piston displacement. The third day will see the free-for-all, a winners' race and record trials, and the conclusion, on the fourth day, will be a six-hour race.

Hill Climb of Ohio "Twin Cities"—The second annual hill climb of the Twin City Automobile Club, of Uhrichsville and Dennison, O., proved no small success, and the several thousand spectators who lined the course saw some keen competition. The hill, although but one-sixth of a mile long, is quite steep, having a grade of 12 per cent. at the bottom, increasing to nearly double that figure at the top. The crowds caused some trouble by getting on the course. The best time, 17 1-5 seconds, was made by W. Stuller, driving a 35-horsepower Jackson, who won in his class and also in the free-for-all.

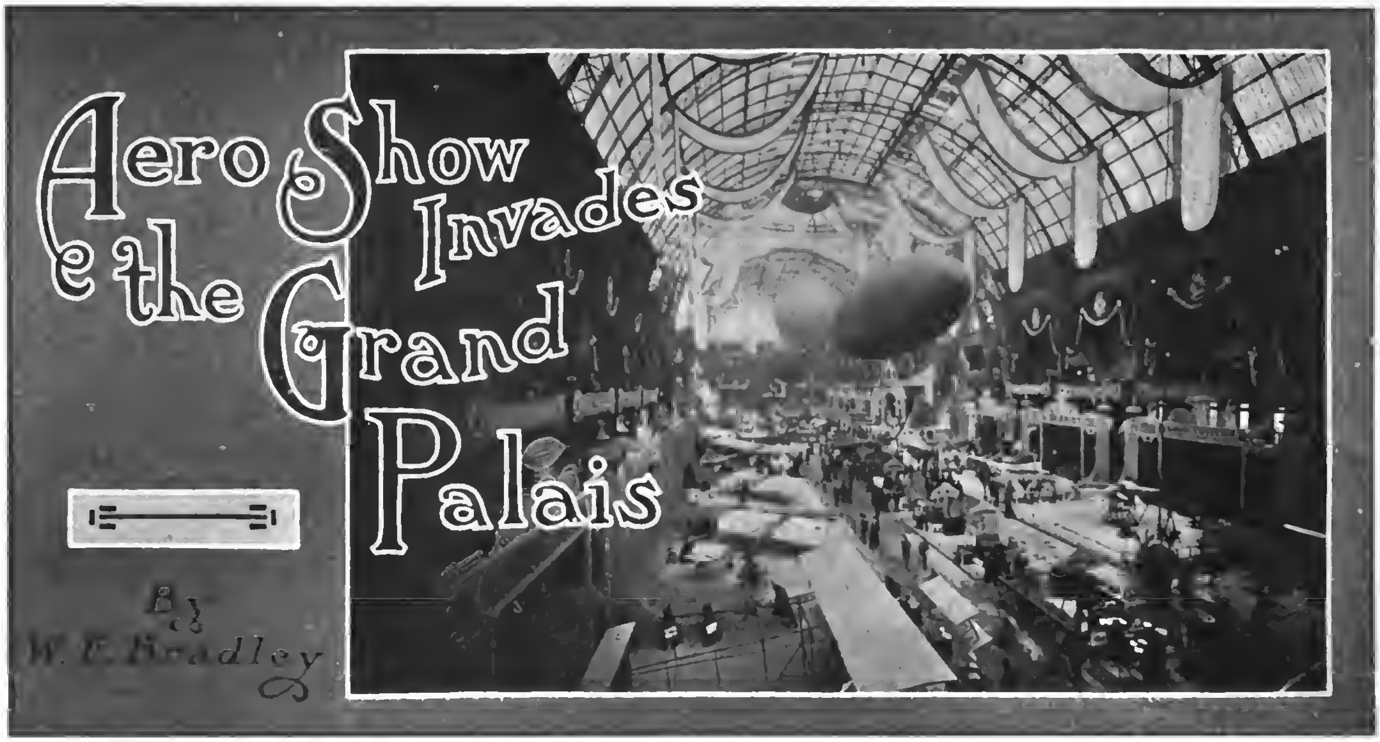
Jackson Wants the W. & S. Trophy—Word comes from Indianapolis that the Jackson Automobile Company has filed a suit against the Indianapolis Motor Speedway to force the latter to award it the Wheeler & Schebler trophy. This is in addition to the suit filed some weeks ago in which the company asks for $100,000 damages. In the 300-mile race for the trophy at the Speedway in August, Lynch, driving a Jackson, was in the lead when the race was called off because of accidents.

Bosch Prize Offer Still Holds—The Bosch Magneto Company says that the prizes it offered for the postponed Brighton Beach 24-hour race will hold in the coming race, October 15 and 16. The prizes, it will be remembered, were $100 to the winner, and an additional $50 if George Robertson's record for this year of 1,091 miles was broken, conditional upon the use of a Bosch magneto on the winning car.



Racing for Good Roads Benefit—A novel plan of assisting the good roads movement in Louisiana has been originated by the New Orleans Automobile Club, namely, holding a race meet, of which the proceeds are to be devoted to the cause. The meet will take place November 20 and 21, following the first annual meeting of the Louisiana Good Roads Convention.

France May Revive the Grand Prix—The sporting commission of the A. C. F. met October 6 to consider the advisability of offering the Grand Prix for a race in 1910. The secretary was empowered to find the sentiment among the manufacturers. If the race is held it will be without any conditions whatever regarding the construction of the competing cars.

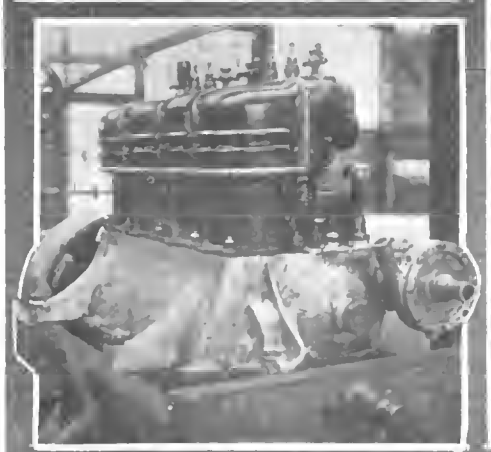


Interior of the Grand Palais Where the Great French Aeronautical Exhibit Now Holds Full Sway

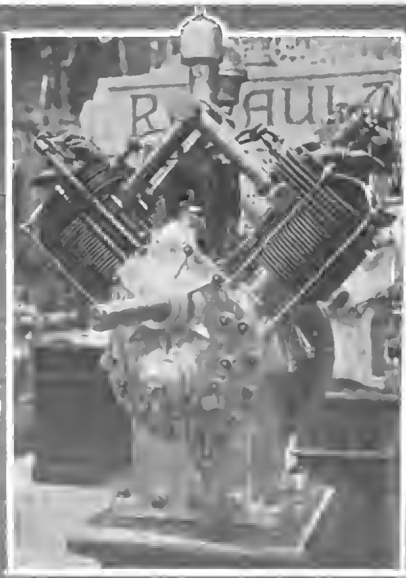
PARIS, Oct. 7—More inventive genius is shown in the motor section of the Paris Aero Salon than in that portion devoted to aeroplanes. With one or two exceptions, the aeroplanes are standard models which have been making flights all the year and are fairly well known to the public. The newcomers, for the most part, are neither convincing nor pleasing in their workmanship. One of the most obvious pieces of plagiarism ever seen is the Fernandez biplane, copied from the Curtiss, which was seen at Rheims. As the American machine only arrived in France toward the middle of August, M. Fernandez is to be congratulated on the speed with which he has produced his copy. Instead of suspending the motor between the planes, Fernandez has put it lower with a transmission by chain to the propeller shaft.

The Bayard-Clément Company has made its appearance in the aeroplane world with a remarkably good-looking biplane, which has not yet made flights, but which should have no difficulty in doing so. The machine is a compromise between the Wright, Farman and Curtiss, the main wings resembling the Wright without being flexible, however, the front elevation rudder is of the Farman type, as is also the tail, and the *ailerons* are very similar to those used by Curtiss. The aeroplane is driven by a four-cylinder Bayard-Clément motor placed behind the pilot, and transmitting to the propeller through a clutch, a spring-mounted shaft with a universal joint and inclosed reducing gear. Maurice Clément, the younger brother of the unfortunate Albert, killed at Dieppe, is now making trials with the new machine. The workmanship, both of the biplane and the engine, is fine.

Airship motors occupy a very large amount of place. Certainly the most interesting is one of the new four-cylinder, 200-horsepower engines about to be fitted to the monster dirigible balloon intended to be sent to England by the aerial way. As the airship's capacity is 6,500 cubic meters (about 270,000 cubic feet), it is possible to equip it with very large engines. The Bayard-Clément Company has selected the same type of motor



Bayard-Clément 45-H.P. Aero Motor

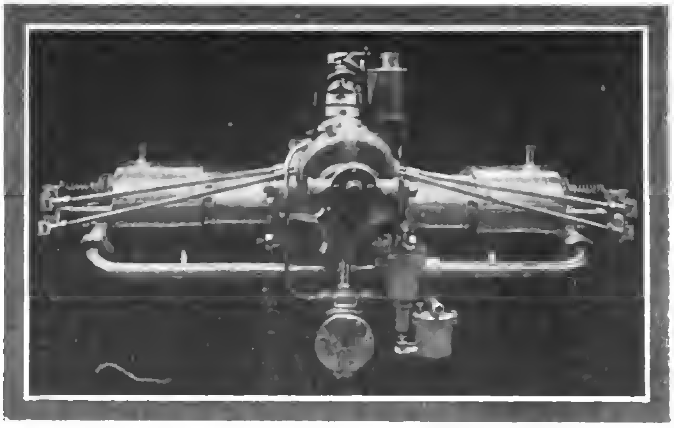


Renault Motor with Camshaft Drive

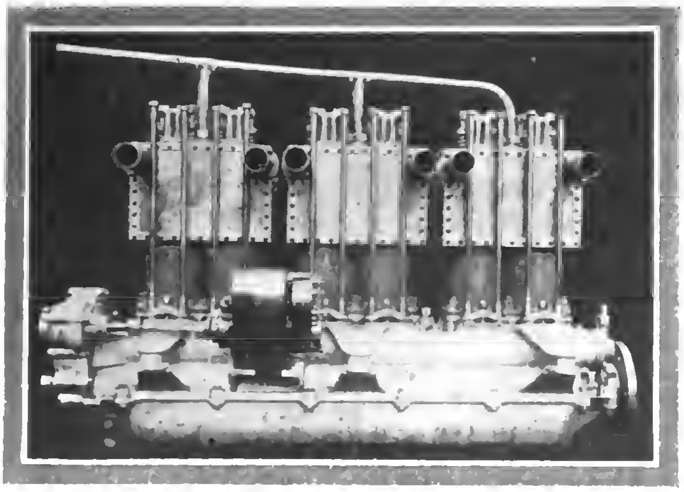
Compact DeDion Aeronautical Motor

as was used on last year's racing cars at Dieppe and at Savannah, but instead of a bore of 155 millimeters has adopted one of 190, or 7.4 inches, with a stroke of 9.1 inches. Each engine is rated at 200 horsepower. In the design only a few details have been departed from the racing-car model. The cylinders are cast in pairs with the valves inclined in the head and operated by an overhead camshaft running right down the center of the motor, exhaust valves being at one side and inlets at the other. A hemispheric combustion chamber is employed with very high compression. For starting, the compression is relieved through a special type of ball compression cock. The cylinders are fitted with rivetted-on copper jackets, through which the water circulates by pump feed. Double ignition is employed, both plugs being just below the inlet valve. The distributor is worked off the end of the overhead camshaft, which, by-the-by, is driven by inclosed gearing, vertical inclosed spindle and bevels. The base of the crank chamber forms the oil reservoir and oil is delivered under pressure to all the main bearings.

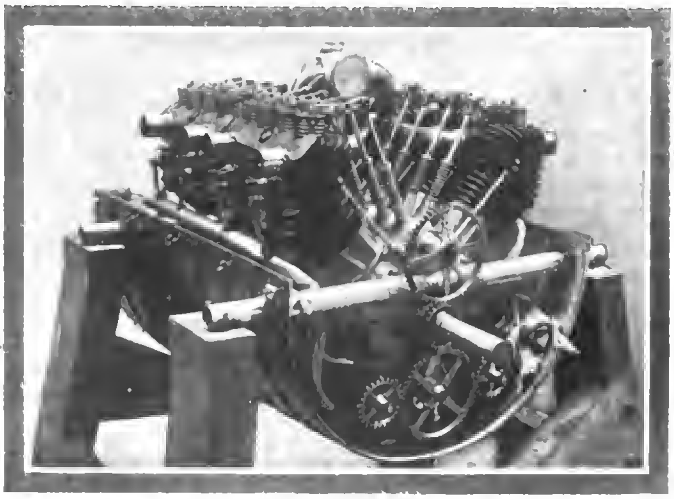
The engines will be mounted on an automobile type of chassis, side by side, each carried on short transverse springs. It is thus possible to disconnect the springs and lift out engine and chassis as one unit. A special type of band clutch is employed with connection by a shaft from this to a gear box, also carried on the chassis. The engines being side by side, lengthwise of the airship, the propeller shafts are at right angles to the engine shaft, projecting respectively to left and right of the steel car. Bevel gearing is, of course, employed, the propellers being mounted in the center of the airship, as on the Zeppelin and the ill-fated *République* Should one engine be stopped, it is declutched and its shaft between the clutch and gear box connected up to that of the live engine by means of a transverse chain. By putting in the low gear it will be possible to make progress. The propellers will be wooden ones built by Chauvière, designed to turn at a low rate of speed.



Darracq 30-Horsepower Two-Cylinder Opposed Motor



Operating Side of Buchet Six-Cylinder Aero Motor

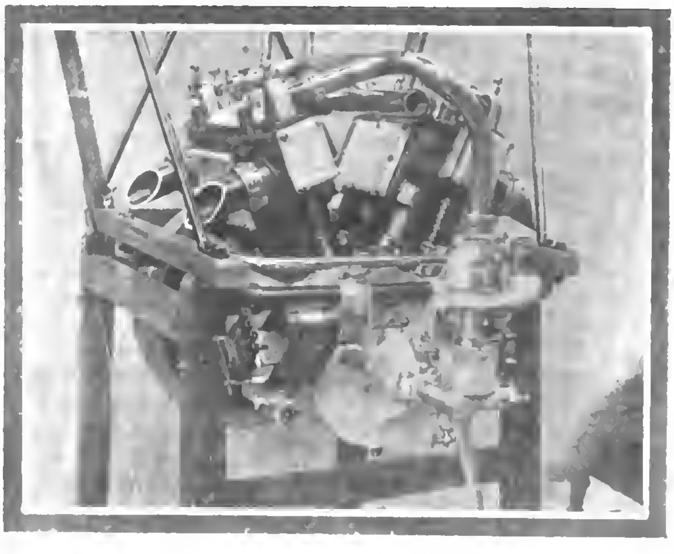


Flat Eight-Cylinder V-Type Aviation Motor

One of the largest motors is shown by the Wolseley Company, of England. Although not the most powerful, it is the largest in overall length, the eight cylinders, cast in pairs, being placed in Indian file. De Dion-Bouton shows several types of eight-cylinder "V" engines, the distinctive feature of which is the use of two independent magnetos mounted on a bracket near the top of the cylinders.

Panhard has had more experience in airship engine building than prohahly any other firm, having equipped all the military airships, including the *Patrie* and the *République*. On the new model, with four cylinders cast separately and fitted with copper jackets, the magneto is carried on the top of one of the cylinders, driven by bevel gearing and vertical shaft. The object is, of course, to give greater accessibility, the usual position being very inaccessible when the engine is of necessity carried on the floor.

There is an even greater selection of engines for aeroplane work than for dirigible balloons, the array comprising every model from the two-cylinder, air-cooled horizontal to the sixteen-cylinder, water-cooled "V" and the twelve-cylinder rotary. Renault has thoroughly gone into this field and has produced several surprises. His eight-cylinder, air-cooled "V" motor is well known, but it was somewhat of a surprise to find that he had also produced a four-cylinder of the same design. On both



Water-Cooled 45-Horsepower Mors Aero Motor these the propeller is carried on the reinforced camshaft. A light-weight, water-cooled model also figured on their stand, the cylinders being separate, with copper water jackets and valves in the head, side by side and operated by a single camshaft. The lower portion of the crankcase, of considerable depth, forms an oil reservoir, from which the lubricant is pumped.

An engine which attracted attention is the one with which Santos-Dumont made his fast cross-country flights. The motor is now the subject of litigation, the Darracq Company claiming that it is a special type loaned by them to the Brazilian aeronaut and Santos-Dumont maintaining that he ordered it and paid for it and can therefore do with it as he wishes.

The engine is of the two-cylinder opposed type, with copper water jackets. Its originality lies in the timing gear, a single cam operating all four valves, carried in the head, and only two gears being employed for the valve mechanism, pump and magneto. This suppression of organs has allowed a reduction of weight without any scraping away of metal in essential parts.

Mors has come forth with an entirely new engine of the four-cylinder "V" type, the cylinders being cast in pairs with their water jackets. This disposition allows the use of a two-throw crankshaft, and as the cylinders are offset in relation one to the other, the connecting rods can be attached side by side to the same crankpin without the use of forked ends. The exhaust valves are mechanically operated, two of them being at the front and two at the rear of the engine, with the inlets automatic and immediately above them. A special type of carbureter is carried with the float chamber placed so low that at whatever angle the motor is placed the level of the gasoline is not likely to be seriously disturbed.

The general tendency among French constructors, however, is to produce an aeroplane engine on standard lines—that is, four or six vertical cylinders, saving weight in the water jackets, valve mechanism and certain portions of the crank case casting. It is the type of motor first introduced by Wilbur Wright. The changes that can be worked on this model are infinite.

Bayard-Clément, for instance, has produced a 40-horsepower, four-cylinder model with all valves on one side in an outstanding pocket. The engine is a single casting with all metal cut away between the second and third cylinders and the usual cast water jacket is replaced by a one-piece copper one. Thus to look at the valve side of the engine the impression is that it is a standard type of motor with valves in pockets on one side only.

Buchet has endeavored to make a saving of weight in a somewhat similar manner. His vertical six-cylinder engine has cylinders cast in pairs with but a framework cast around the two sides and the ends of the cylinders, and to this framework the aluminum flat plates forming water jackets are screwed on. The arrangement allows the thickness of the cylinder walls to be verified with accuracy and naturally decreases weight, for the aluminum plates are much lighter than a cast jacket. All valves are on one side, thus requiring but a single camshaft, and are in the head, side by side. One of the features of the engine is that the piston is bored with holes in all its lower portion.

Antoinette shows the first of the new sixteen-cylinder motors with the cylinders in V. The only respect in which this differs from the eight-cylinder model used by Latham is in the number of cylinders, the engine being practically two eighths on a crank case of double the usual length. The new model in both eight and sixteen cylinders has one-piece copper-deposited water jackets. This allows a cylinder with a fixed head, and as the only joint in the jacket is at the base of the cylinder the possibility of leaks is reduced to a minimum. Formerly the separate head was liable to allow leaks from the cylinder into the jacket, the water being driven out and overheating occurring. A very similar type of jacket is employed on the E. N. V. motor used by Blériot and on the new Brouhot eight-cylinder motor.

Gabriel Voisin, the maker of the well-known type of biplane, after fitting his biplanes with any type of motor selected by his clients, has now built an engine after his own ideas. It has four separate cylinders with copper jackets and concentric valves in the head. The cylinders are given considerable offset and are mounted on an aluminum crankcase, the sides of which are screwed on. The timing gears are contained within the crankcase and not in an extension, being reached only by taking down the sides of the crankcase. The high-tension magneto is carried on a bracket at the rear of the engine immediately above the crankshaft, its gears being within the case.

Americans Plowed Best at Amiens

On the Field at Amiens During the Agricultural Trials Which Were Won by an American Tractor Plow

AMIENS, FRANCE, Oct. 5—France is seeking to encourage the use of the internal combustion motor among agriculturalists, both for work on the farm and for the transport of farm produce. The methods pursued are to hold an exhibition annually in different parts of the country and at the same time to put on foot various competitions.

The spot chosen this year is Amiens. But the northern Frenchman seems to be harder to convert than his compatriot of the center. Manufacturers appear to know of this, many of them who were present at the last exhibition held at Bourges being absent at this. The agriculturist comes in numbers to see the new-fangled notions, but he comes with his mind made up that they are not much good. Thus, before it is possible to sell him a machine, it is necessary to convert him, and the task is not an easy one.

The exhibition comprises two large halls with an open-air exhibition between them. Apart from the purely agricultural exhibits the hall contains gasoline and gas engines of various types, most of them driving agricultural machinery. The French manufacturer is convinced that the best type of motor for stationary farm work is a single vertical cylinder. The long-stroke, slow-speed horizontal motor so commonly employed in America for this class of work is not seen here.

The Ceres Company had one of the neatest outfits in this line, the engine being mounted on a truck and connected by belt to a countershaft with a series of pulleys from which the drive could be taken to the various machinery. The engine, which was of practically standard design, was cooled by a circulation of water contained in a circular radiator mounted on the truck, the center of the radiator containing a fan driven by belt off the engine. The entire outfit was protected by a galvanized iron roof. Small stationary engines for pumping water or driving light machinery were plentiful, most of them being mounted on portable platforms. Magneto ignition is employed on even the smallest of these outfits.

Instead of being shown in the exhibition hall, the automobiles designed for farmers' use were kept on the road giving demonstrations of their ability to do a day's work. Working with the three or four French trucks was an American buggyabout, the first of its kind ever shown in this portion of Europe. It was shown by the French branch of the International Harvester Company. French automobile manufacturers have made no effort to provide a vehicle for the farmer, for it cannot be maintained that the low-powered, low-built runabouts introduced at these exhibitions is an agricultural vehicle. As plowed fields are the same the world over, and even highly developed France has byroads that cannot be traversed by the standard type of automobile, there is no reason why the American buggyabout should not be adopted by the agriculturists of France.

Plowing without the use of horses was one of the most important features of the Amiens exhibition. Here honors fell to the Cima, under which title is hidden a tractor produced by the International Harvester Company. This machine worked with perfect regularity, plowing on the first day 3 1-2 acres of land in 5 hours 55 minutes, with a consumption of 8 4-5 gallons of gasoline and 4 1-2 gallons of water. On the second day the same machine worked 6 hours 35 minutes, plowing 3 3-4 acres, with a consumption of 9 3-5 gallons of gasoline and 16 gallons of water. The American machine was awarded the first prize of the Automobile Club of France.

Neither of the two French machines was able to get through a day's work. The competitors were of two entirely different classes, the Landrin being a tractor, like the International Harvester Company's machine, while the Bajac operated by winding drums. The Landrin had a standard type of four-cylinder engine mounted on a stout chassis, drove to the rear wheels through side chains, and at the rear had a revolving drum with plowing blades driven by chain from a countershaft on the chassis. As the ground in the neighborhood of Amiens was particularly rocky the blades did not last long; they first buckled up, then broke off altogether.

The Bajac, with its winding drums, was some time before it could be got into working condition. When it did start its furrows were not made with all the straightness demanded by critical agricultural eyes. A two-cylinder vertical engine provided the motive power to the winding drums, which were driven by an overhead shaft meshing with a large pinion on the end of each drum. A special type of plow was employed, an operator sitting on a bogey attached to it and directing its course and depth of operation. When the end of the field was reached the plow was swung round without the plowman descending from his seat and operation in the opposite direction was commenced. As this machine needed three men, one on the plow, one at the engine and another at the winding drums, it was obviously costly to work.

The American machine was the standard pattern operated by a long-stroke, slow-speed, horizontal single-cylinder gasoline engine. The plow was towed behind, the operation only requiring the presence of two men, one being on the tractor and the other at the plow.

A useful competition was held among mechanics and farm workers in testing their ability to repair motor and various types of agricultural machinery. A stationary engine was purposely put out of business in some artful manner and the competitors, some twenty in number, invited to find the cause of the breakdown and repair it as quickly as possible. Various farm machinery was treated in the same way.

A conference on the use of motors in agriculture was held during the exhibition period, the delegates representing practically all countries in Continental Europe interested in agriculture.

SALZER, MERCEDES, SEMMERING HERO

Berlin, Oct. 1—The Semmering hill climb, the blue ribbon of Austrian motoring, was held on the 19th over a distance of ten kilometers on the tortuous Semmering road. The course was in splendid condition and the entries, though not as numerous as last year, included drivers of international repute. such as Cole, Poege, Salzer, Lindpaintner, Joerns, Duke Ludwig Wilhelm of Bavaria, Prince Francis Joseph of Braganza (whose brother has just married Miss Anita Stewart), Count Kolowrat, etc.

The hero of the day was Salzer in a Mercedes, who beat the Semmering record in splendid style, covering the distance in 7 minutes 7 seconds, definitely winning the trophy for Anton Dreher, Vienna's prominent sportsman. The class he started in was for vehicles without restriction, and he beat W. Poege's Mercedes by 6 2-5 seconds, with Cole in the Benz third in 7 minutes 28 4-5 seconds.

Others who were placed were Joerns and Lindpaintner, both in Opels, while Prince Francis Joseph did not finish. In the section for cars from 35 to 46-horsepower, Joerns carried off the prize in 7 minutes 54 3-5 seconds, beating Cole in the Benz.

GERMAN CARS FOR 1910 GRAND PRIX

Berlin, Oct. 1—In the Grand Prix of 1910, which is said to be looming on the horizon, it is stated that three German firms have announced their intention of participating—Mercedes, Benz and Opel. There will be no voiturette tour in Germany this autumn after all, as the industry cannot see its way clear to participate in such an affair at this late date, and the event will probably take place next spring. The German victory in the last Grand Prix has greatly stimulated the racing spirit.

AMERICAN CARS POPULAR IN NOVA SCOTIA

The following information concerning automobiles in Nova Scotia is furnished by United States Consul Alfred J. Fleming, who is stationed at Yarmouth:

Yarmouth has only a trifle over 6,000 people, yet there is a great deal of wealth here, and this is revealed in a very pronounced manner by the number of automobiles owned. There are about 110 automobiles in Nova Scotia, and 36 of these are owned in this city, Amherst having 30 and Halifax 25. The 36 autos in Yarmouth cost $44,475, 32 being American make, 3 Canadian and 1 English. Of the $44,475 invested, all save $7,000 was spent in the United States, which is in itself an evidence that the American-made machine is popular in Canada. Of these 36 machines, 16 are runabouts and 20 tourist cars. Most of them are good machines and a few of them are first class.

Counting the 110 machines in Nova Scotia at the average price of the Yarmouth machines, makes $135,811 invested therein in this province, and if the same average as to place of make holds good as in the case of Yarmouth, nearly all this money found its way to the United States.

The roads in this province are exceptionally good for automobiling and are praised by the scores of American autoists who have visited Nova Scotia. One drawback to automobiling here is the law prohibiting the running of machines in the various towns and counties and municipalities on certain days. For example, automobiles cannot run in Yarmouth County, outside the city, on Saturday; Digby County has one or more prohibited days; Annapolis, Kings, Queens, etc., have days in which autoing is forbidden by local regulations, municipal and town ordinances

HAS AN EYE ON FUTURE BUSINESS

A Swiss hotel keeper, with the foresight that is characteristic of his race, has erected on the top of his garage a huge sign which reads as follows:

GARAGE

AEROPLANE STATION

The second line, which is intended to be easily deciphered from an elevation above the earth's surface, is addressed to prospective guests who may arrive by aeroplane or dirigible.

Bajac Plowing Machine at the Amiens Trials—Operated by Winding Drums at Each End of Field

Misfiring: Some Causes and Some Remedies

By Stillman Taylor

AMONG the little things which occur with more or less frequency to vex the driver of the automobile, there are none more troublesome than misfiring. Misfiring, or the failure of some part of the ignition system to perform its regular functions, may be caused by a number of things, many of which are likely to be overlooked owing to their apparent insignificance. When misfiring occurs, the autoist very naturally concludes that the fault lies in the ignition system, and as this is the most complicated and delicate part of the whole car, the supposition is often correct. Yet it often happens, however, that the carbureting apparatus is the real offender, and if the complete electrical plant has been systematically examined throughout and the trouble still exists, it is reasonable to presume that the trouble is in the fuel supply system.

Among the causes which contribute to misfiring may be mentioned ignition troubles, such as short-circuit in wires, exhausted battery, pitted or improperly adjusted vibrators of the coil, sooty or cracked plugs, loose connections or switch, dirty timer or commutator, punctured condenser, moisture in coil, wet wires or cables, water on distributing plate, dirt on contacts in distributor or wear there, or dirt or wear in timer.

Carburetion and Fuel—Faulty mixture, sediment or water in the carbureter, clogged gasoline strainer, leaky float, clogged spraying nozzle, bent float-valve spindle, stale gasoline, partial stoppage of fuel supply pipe, hole or obstruction in intake pipe or manifold. These are not all the things that might happen, but are the principal ones which the writer's experience has suggested as most likely to occur to cars in general. We will take them up in their proper order of classification, first dealing with those failures attributed to ignition, followed with a list of carbureter and mixture troubles likely to produce kindred results, and so cause misfiring.

Troublesome Short Circuits—Either a partial or a considerable leakage of the electrical current may be due to worn or frayed insulation, and the bare wire may possibly come in contact with some metal part, and so form the short-circuit to the ground. This may or may not prove a constant short-circuit, as it sometimes happens that the vibration of the car will cause the bare wire to shift about, and the "short" will occur only now and then, as the wire brushes against the metal at intervals. Trouble of this kind is generally due to poor and old-time connections, and will but seldom occur with modern terminals. Perhaps the easiest and best way of correcting this trouble is to wrap a little tape around both the ends of the damaged cable and its binding post, which will keep the loose ends together and at the same time make certain of a good contact at the post.

Failures of the spark plugs due to defects in material and manufacture are not so common nowadays as in the past, but modern plugs are by no means immune from trouble. It is well to test the plugs in the event that trouble is suspected. To do this it should be first ascertained which of the cylinders is misfiring by holding down all the vibrators but the one to be tested. This is inconvenient without assistance, but the vibrators may be cut out of action by simply inserting a bit of stout paper between the platinum contacts. When the missing cylinder is found, unscrew and examine its plug, and if the points are clean and everything looks all right, connect up the high-tension wire, lay the plug on the cylinder, and turn the motor over until the proper contact is made. In case no spark is forthcoming and the plug is clean and to all appearances in good condition, it is very probable that the porcelain has developed a crack sufficient to form a leak and cause a troublesome and elusive "short."

The reader should remember that this method of testing a plug is not infallible, since a minute crack in the insulation (not always visible to the eye) may not interfere with the production of a good spark in the air, but will cause leakage and so make a weak spark, or none at all, when called upon to overcome the greater resistance of the compressed gas. The electric current will always follow the path of least resistance, and as it is called upon to overcome considerable resistance in jumping between the two electrodes of the plug, it is obvious that a comparatively small defect in the insulation will prevent the production of a fat spark at the points.

Broken and wet wires are occasionally the source of misfiring, and although little trouble may be anticipated from the well made modern cables, the wiring of older cars—so largely seen in second-hand shops—is frequently defective. The writer has had some little experience in "tinkering up" these old sleds, and several times traced misfiring in the ignition system to a broken wire in the primary circuit. Where the wiring bears unmistakable evidence of having seen better days, the only satisfactory remedy is to put in new wiring throughout the car.

Wet wires are likewise the cause of considerable trouble in the older cars, as in many instances the high-tension cables are carried underneath the flooring and, being unprotected, are likely to get short-circuited through the water and mud splashed up by the wheels. In cases of this kind, the writer has often found it desirable to re-wire the entire system when possible. In some cars, where this is not convenient, an old length of rubber hose may be pressed into service to enclose and partly protect the otherwise completely exposed wires.

Worn and Pitted Contact Points—The platinum contact points of the tremblers of the coil should not be allowed to become pitted and uneven through neglect. If not properly attended to, the points will become rough and jagged and the poor contact will result in misfiring. The points should be examined occasionally, and, if uneven, they should be trimmed flat with a fine jeweler's or manicurist's file. The adjustment of the vibrator screw also plays an important part, and should be given its share of attention. A stiff tension is never necessary or desirable, as it will not only consume a greater amount of current, but will result in rapid wear and pitting of the contacts. The trembler should be adjusted with only sufficient tension to cause it to vibrate at a moderately high pitched buzz. This adjustment by ear rests altogether with the experience and judgment of the driver, which may or may not be good.

When the unit coil system is used—and this arrangement is now in general use—it is important for the best coil service that the vibrators of the several units be tuned as near alike as possible. This may be closely approximated by sound, but the only sure method is to measure the consumption of the current by means of a special ammeter. The exact amperage varies somewhat in different coils (from 1/2 to 3/4 amperes) and to obtain maximum efficiency the maker's directions should be followed.

Exhausted Battery—A rundown battery is a very common source of misfiring, and although the symptoms are plainly apparent in troubles of this kind, the difficulty is not always traced to the proper cause. The fact that a weak battery will not generally prevent starting, and only misfires after the car is well under way, is, no doubt, the reason why the real trouble is not at once suspected. And again, the motor may run fairly well at medium speeds, but when the throttle is opened to admit more gas, the spark is too weak to fire the heavier charge, and the motor commences to misfire, finally coming to a stop. In fact, when the battery fails to respond to the spark advance lever it may be taken as pretty good evidence that the voltage is too low, and a new set of dry cells should be connected up, or the battery re-charged if of the accumulator type.

If the two sets of dry cells are used, they may be made to give some little additional service by connecting up its series (carbon to zinc). If two storage cells furnish the ignition current, connect them up in parallel (carbon to carbon and zinc to zinc). To avoid the annoyance of a weak battery, each dry cell should be occasionally tested for amperage and the defective cell renewed. A storage cell should de charged regularly once a month, and should never be allowed to become discharged.

Switches occasionally work loose, and, while an uncommon source of misfiring, it will occur now and then. A loose switch generally provides such poor contact that the motor will stop completely, but it may also cause missing in but one or two of the four cylinders.

The timer or commutator should be washed out thoroughly with gasoline at least once a week, to remove dust or other substance which will likely interfere with a perfect contact. If neglected, and dust and oil allowed to accumulate, the contacts will be imperfectly made and the current being poorly distributed, misfiring will ensue.

Condenser and Short-Circuit in Coil—The condenser is not likely to cause trouble, and the most serious injury likely to befall this important part of the spark coil is a puncture caused by the use of a battery generating a higher pressure (voltage) than the coil will stand. In this case the coil must be sent to the makers for repair. It occasionally happens, however, that misfiring results from a broken connection to the condenser, or is due to the presence of dust or oil on the spring contacts. If trouble is suspected in the condenser, the contacts should be examined and cleaned with a bit of cloth wet with gasoline.

Water or Moisture in the Coil—Will form a short-circuit and produce missing in the cylinder, and will rapidly exhaust the battery current. A primary or single wound coil—such as is used in low-tension make-and-break ignition—may be dried out, but the only way to fix up the high-tension coil is to send it to the manufacturers.

In addition to those misfiring troubles which have just been mentioned, many of which are common to both magneto and battery systems, there are a few misfiring troubles which are confined to the magneto itself. Owing to the fact that many autotoists regard the magneto as a balky and mysterious machine, the reader may possibly find some meat in this somewhat desultory summary of the writer's experiences.

Perhaps one of the most common causes of magneto misfiring is due to the interrupter-contact-arm roller becoming worn. A fiber roller will often wear unevenly, causing the cam to slip over the worn flat spot without making a good contact. In case of steel rollers and fiber cams, the latter will sooner or later show signs of wear. The contact interrupter spring is also a common source of missing, as the spring loses its elasticity and becomes weak through constant use. Loose interrupter contacts are not quite so common, but will occasionally cause misfiring by working loose and so provide insufficient surface to insure a good contact.

Armature bearings work loose in course of time and cause misfiring by making too short a contact. Dust on the insulated face of the distributor is likewise conducive to missing, and the autoist should make it a point to keep this surface clean.

Carbureter and Mixture Troubles—Foremost among the several difficulties which may be called common misfires, is the lack of a proper mixture. A rich mixture containing a relative large proportion of gasoline in proportion to air is never desirable, inasmuch as it deposits considerable soot upon the piston, cylinder walls, and valves, and is, moreover, a waste of fuel. The motor will seldom run well on a rich mixture, and the carbureter should be so adjusted that no more gasoline is fed to the mixing chamber than is sufficient for the motor to develop its full power. The exact mixture may be found by experiment.

A very rich mixture will cause misfiring; the motor will have a tendency to choke at other than high speeds, and is likely to overheat. A lean or thin mixture will, on the other hand, lower the efficiency of the motor, and it will have a marked tendency to miss at high speeds, accompanied by a popping sound in the carbureter. This is due to a weak mixture, and the needle valve should be adjusted to admit more gasoline, or if due to an excessive supply of air, the auxiliary air-valve should be adjusted to admit less air.

Bent Float Spindle and Leaky Float—Either one of these will cause missing in one or more cylinders. The float spindle may become bent or it may become jammed into its seat by too vigorous priming. This may be discovered by unscrewing the cover and lifting out the float. Considerable care should be taken in straightening out a bent spindle, and the metal should be placed upon a block of hardwood, another block interposed, and the spindle gently tapped with a hammer.

A leaking metal float or a fuel-logged cork will cause missing owing to its uncertain and erratic action. A cork float should be thoroughly dried out and then given a couple of coats of shellac to prevent it from absorbing the gasoline. As a new float is not at all expensive, the reader will probably find it more convenient to put in a new one. A metal float must be soldered when it leaks, and as the copper is thin and easily damaged, only a very little solder need be used. Precaution should be taken to keep the hot soldering bit away from the metal.

A clogged gasoline strainer is often the cause of trouble, and this is about the first thing that the autoist should examine when the misfiring is apparently in the fuel supply system. The brass gauze strainer should be frequently taken out and cleaned of any dirt that may have been filtered out of the gasoline.

An Obstructed Spraying Nozzle—Owing to the small needle-like opening in the spraying jet, it is not uncommon for a particle of grit to lodge in the orifice and partially stop the flow of gasoline. The obstruction will not always interfere with starting, but as soon as the motor speeds up the amount of gasoline sucked through the nozzle will not be sufficient for the motor at higher speeds, and it will soon begin to misfire until the motor slows down to first speed. A leak in the intake manifold will cause misfiring in one or two cylinders, and is often mistaken for ignition trouble. The cause may be due to loosening up of the bolts securing the flange to the cylinder.

The inlet valve is often the seat of the trouble, and missing here is generally caused by a weak or broken spring, a bent stem, or a carbonized valve. If the valve spring has lost its temper and broken down, the tension will be insufficient to properly hold the valve on its seat and the gas will partially escape and so cause missing. The insertion of an iron washer or two will increase the tension of the defective spring and serve as a temporary road repair.

A broken spring may be similarly repaired by placing a washer between the broken ends. A bent valve stem should be taken out and carefully straightened by laying it upon a billet of wood with another block interposed between it and the hammer. Only a very little force is needed, and the stem should be repeatedly tried until it slides freely in its guide.

Oil on Garage Floors—As an indication of carelessness on the owner's part, nothing is quite as effective as a neat little puddle of oil in the mathematical center of the floor, directly underneath the car. When it becomes necessary to lie down under the car to repair or adjust some part, this cunning little puddle of lubricant helps a lot toward the comfort of the man doing the work. The method of fixing this in the public garage is well worth copying (?). When a pool of oil collects on the floor there, the preferred way of fixing it is to sprinkle sawdust over it. The oil-soaked sawdust pile will make a fine starting point for a fire as soon as some thoughtful friend supplies the match necessary to start it.

DIRECT FUEL INJECTION TWO-CYCLE MOTORS

By THOS. J. FAY.

DIRECT fuel injection, as an adjunct to two-cycle motors, represents one of the most promising features, and designers of acumen recognize the possibilities. If the fuel is induced into the crankcase with the air, the mixture, if the crankcase compression is maximum, becomes combustible, and with the usual arrangement of ports it is extremely difficult to (always) prevent crankcase shots. The prime source of this class of trouble is due to having fixed ports with the inlet and exhaust simultaneously open coupled with a variable terminal pressure. If the terminal pressure is for any reason unusually high, some of the products of combustion in a flaming state will enter the crankcase with the usual consequence, *i. e.*, a crankcase shot, so called.

If the fuel is directly injected, which is a matter of providing a suitable injector and placing it in direct communication with the cylinders of the motor, the crankcase compression will then reduce to the compression of pure air, which, being non-explosive, crankcase shots will be eliminated even though flaming products of combustion may still enter the crankcase.

If the air in the crankcase does become contaminated (fouled) it is not such a serious matter under the conditions of direct injection of fuel, since the compression in the cylinder may be established at a point so high that preignition would be assured were the fuel mixed with the air too early. By timing the fuel injection so that combustion will be propitious, the compression may be just as high as mechanical considerations will allow of.

Products of Combustion Will Not Defeat Power—That contaminated mixture can be utilized even advantageously is shown by the story of nitrogen in the mixture, which represents 11.8 out of 15.3 pounds of atmospheric air, as required to induce complete combustion of one pound of gasoline. In other words, all fuel is encumbered with a large proportion of inert gas, and this is the reason why it can be used. The compression must be regulated to suit the dilution of the fuel with inert gas. Products of combustion must be classed with nitrogen (as an inert gas) with the exception that they are superior to nitrogen for the purpose, due to the presence of a little fuel value in the products (which is not so with nitrogen) and to the further fact that the products of combustion are in a heated condition, which in itself is of more than a little advantage when account is taken of the specific heat of gas mixtures, ranging as it does between 0.20 and 0.24.

Correct Mixtures by Adjusting Fuel—If a certain proportion of fuel under certain conditions of compression, will induce satisfactory results, then, within certain limits, other proportions of fuel, under other conditions of compression, will be followed by substantially equivalent results. True, the amount of oxygen in proportion to fuel present must be adequate to propagate flame, but this is a limitation which may be readily realized even when a considerable percentage of spent gas is present, provided the compression is adequately increased, with one other proviso, *i. e.*, the fuel and the gases must be thoroughly intermingled to prevent stratifying.

If the fuel is projected into the gas body, as it will be when a suitable fuel injector is employed for the purpose, the mixture will not stratify, since the force of the sprayer will be spent in the process of distributing the minute globules of fuel to all parts of the gas body. In the presence of a suitably high compression the fuel (in view of considerable excess heat) will be rendered volatile at a high rate of speed and the logical conclusion is that two-cycle motors become at once practical under the conditions as follows:

(A) With a crankcase compression of from 5 to 7 1-2 pounds per square inch limited to atmospheric air, provided the transfer ports are suitably waterjacketed, free from undue bends, short and of adequate area.

(B) If the cylinder compression is so high that the rate of flame propagation will be adjusted properly despite the lack of complete scavenging.

(C) If preignition is aborted, which is a matter of timing the fuel injection.

(D If the fuel injector is so contrived that it will project a spray of fuel into the compressed body of air, etc., in sucn a way as to cause the fuel to volatilize quickly and defeat stratification.

(E) When the cylinders are maintained at a working temperature, which is a matter of properly jacketing and circulating a cooling liquid, as water, at a sufficiently rapid rate, with the understanding that the heat will be sponged out of the water as fast as it is taken away from the cylinder walls, through the use of a radiator of adequate capacity to absorb heat.

Commercial Examples Show Results—Fig. 1 depicts a motor of the two-cycle class, in which the fuel is injected in the stream of air as it rushes through the orifice of the transfer port from the crankcase. The fuel enters the injector at A, passes into the body B and is fed out through the supply pipe C to the nozzle D, which lies in the stream of inrushing air from the crankcase, which in turn enters the cylinder through the transfer port E which is short.

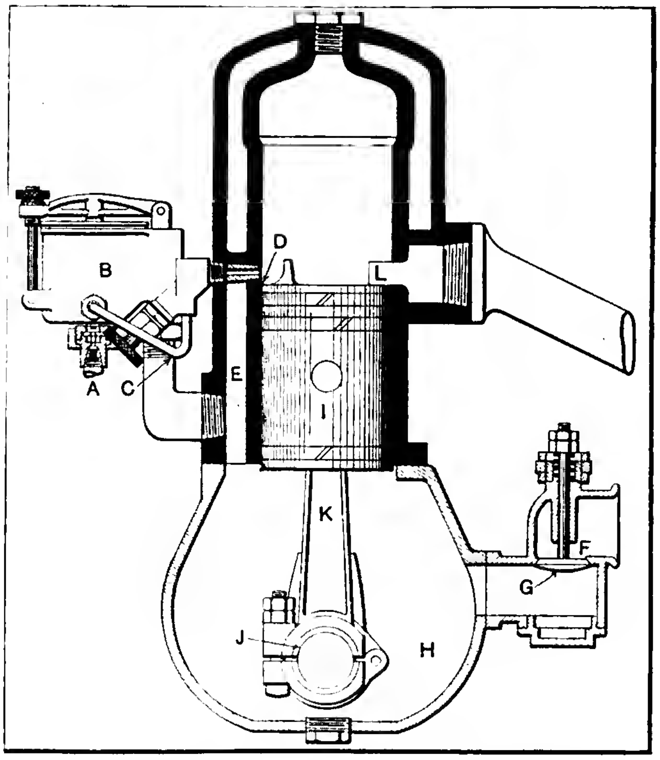

Fig. 1—Type of two-cycle motor with direct fuel injection

Atmospheric air enters the crankcase through the orifice F by the automatic valve G into the chamber H, where initial compression takes place, due to the displacement of the decending piston I in obedience to the stroke of the crank J interconnected by the connecting rod K. Compression takes place when the piston I ascends. On the down stroke following compression the charge, having been ignited at the proper time (just before the completion of the compression stroke) delivers up its energy and just before the end of the stroke the exhaust L is uncovered (in advance of the induction port) at the termination of the induction port E. Due to early opening of the exhaust port L, the exhaust rushes out at a sufficient rate to reduce the terminal pressure below the crankcase compression, so that when the induction port is uncovered the compressed air from the crankcase (picking up gasoline en route) is enabled to enter the cylinder in proportion as the exhaust products pass out.

The two-cycle relation is established since the action is such that a power stroke is induced for each complete revolution of the crank in each cylinder of the motor following the action as above indicated and a more continuous torque results.

In this motor the fuel is well mingled with the air, because it is forced in as a spray at the throat of the transfer port on the induction side, due to good crankcase compression.

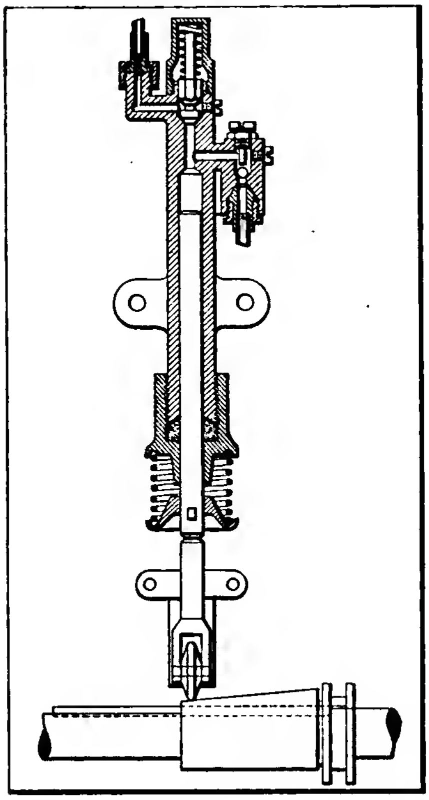

Fig. 2—Fuel pump showing sliding cam contrived to alter the stroke of the plunger at will

When a Timed Fuel Injector Is Used—There is further ground for experimenting, as when a timed fuel injector is employed, the difference being that the fuel will then be injected just before ignition with an interval of time sufficient to assure that the fuel will vaporize and mingle with the compressed air in such a way as to bring each molecule of oxygen in contact with its quota of hydrogen or carbon. Fig. 2 depicts just such an injector, and mechanically there are several ways of adjusting for time of injection, one of which, the sliding cam, as shown, seems to be the more simple.

The main reason for discussing this phase of the fuel-injection problem is to keep in mind the possible advantage attending the increase in compression which will be rendered possible if preignition is entirely eliminated, and this will be so if the fuel is timed so that if it does ignite without the aid of a spark it may be timed so that it will do useful work just as it would were the spark effective.

There is one other (possible) advantage attending the use of an adjustable pump, *i. e.*, the fuel will not be in the incoming crankcase charge, so that if some of this charge should "sneak" out with the exhaust it will not be at the expense of fuel; the fuel would be injected after the exhaust port closes on the up stroke of the piston.

It is not to be supposed that in a two-cycle motor (with given piston displacement) the mixture can be made so efficient for the purpose that the same amount of power per stroke will be realized as in a four-cycle motor of the same displacement. Were it possible to render the conditions of scavenging equal in both cases, then, and then only, would the strokes be equal as respects power delivered. In two-cycle motors the aim is to afford a rapid series of twisting moments and depend for result upon doubling the number of such moments, hoping that each power increment will be at least equal to one-half the ability of a single twisting effort in a four-cycle motor. If each twisting effort in a two-cycle motor can be made to exceed the turning moment unit in a four-cycle motor, then the two-cycle motor, size for size, will deliver more power. Two-cycle designers claim that this advantageous state is in evidence even when the two-cycle motor is designed in the most simple way.

LIGHTING EQUIPMENT DEMANDS ATTENTION

Much has been said about the ability of acetylene generators, and true to the story, they are of very excellent characteristics, taking them as a whole. There are one or two small matters, however, which do not always receive the maximum of attention even at the hands of builders of cars when they furnish generators. It is not uncommon to note that the generators are installed without a gas bag to take the fluctuations, and in the absence of the same, the light flickers. After a time if there is no water trap the presence of excess water in the piping leads to the same trouble and it is even possible to find cars in which no attempt is made to drain the water to a low point. The device here illustrated shows how this matter might be disposed of, although the principle may be incorporated in without going to the mass of detail as presented.

The piping should be well installed, and to place the same in a protected position would seem to be well worth while. The copper piping frequently used is both small and thin of walls, and unless it is annealed it is prone to fail in service. Any autoist who finds that the piping is brittle, which is a sure sign that it has not been annealed, may readily perform the operation by simply heating the pipe after it has been coiled up to render it easy to handle, and when it approaches a clear red quench it in water. Steel is rendered hard by quenching, but copper follows a reversal of the law, and is rendered soft.

Oil Lamps Must also Be Cared For—The following observations apply directly to oil-lamp equipment, they being somewhat revamped to suit automobile conditions, otherwise they are very old indeed:

(a) Keep the lamps scrupulously clean; this is one of the most important details.

(b) Select wicks that are the right size for the lamps; they should be a snug fit in the wickholder.

(c) The wicks should be just long enough to reach the bottom of the oil well and no more.

(d) The wicks should not be too tightly plaited; soft wicks will best serve the purpose, and when they get hard they should be discarded.

(e) New wicks should be dried out before they are put in the lamps.

(f) Before lighting, the wicks should be dipped in the oil.

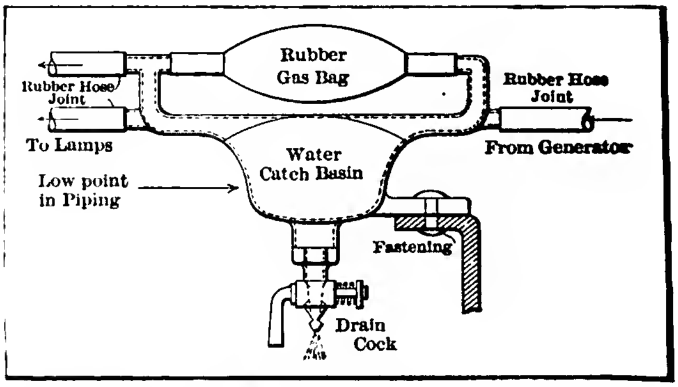
(g) The oil well should be kept full of kerosene.

(h) In properly designed lamps the wick should pass to the bottom, inclosed all the way by the wickholder or some other suitable means as a safety device and to keep the wick in place. The inclosing holder should be open at the bottom.

(i) After lighting the lamp, turn the wick down and then slowly raise it to the right height. The exact right height cannot be determined until the lamp warms up.

(j) The oil can in which the kerosene is kept should be closed in order to shut out water, which oil will absorb to a vast extent if opportunity affords.

In this state anything but a good light will be given off, and the lamps will snuff out readily.



Scheme for Holding Gas Bag and for Draining Piping System

How Warner Timing Device Does Its Work

Messrs. Baker and Warner Using the Timer

TIMING in automobile competition now requires more accuracy than can be had by even the most expert handling of stop watches, as the difficulties of this method increase in proportion to the speed of the cars. Realizing that the degree of accuracy required was beyond the attainment of human eyes and hands, E. H. Warner, of the Warner Instrument Company, and Walter Baker, whose connection with racing dates back to the Baker electric "Torpedo," co-operated to produce an electric device which would perform the duty of timing, and the Warner timing instrument was the result. At Indianapolis, Lowell and Riverhead this instrument kept account of the speed performances of the contestants, supplying automatically indisputable figures for each lap.

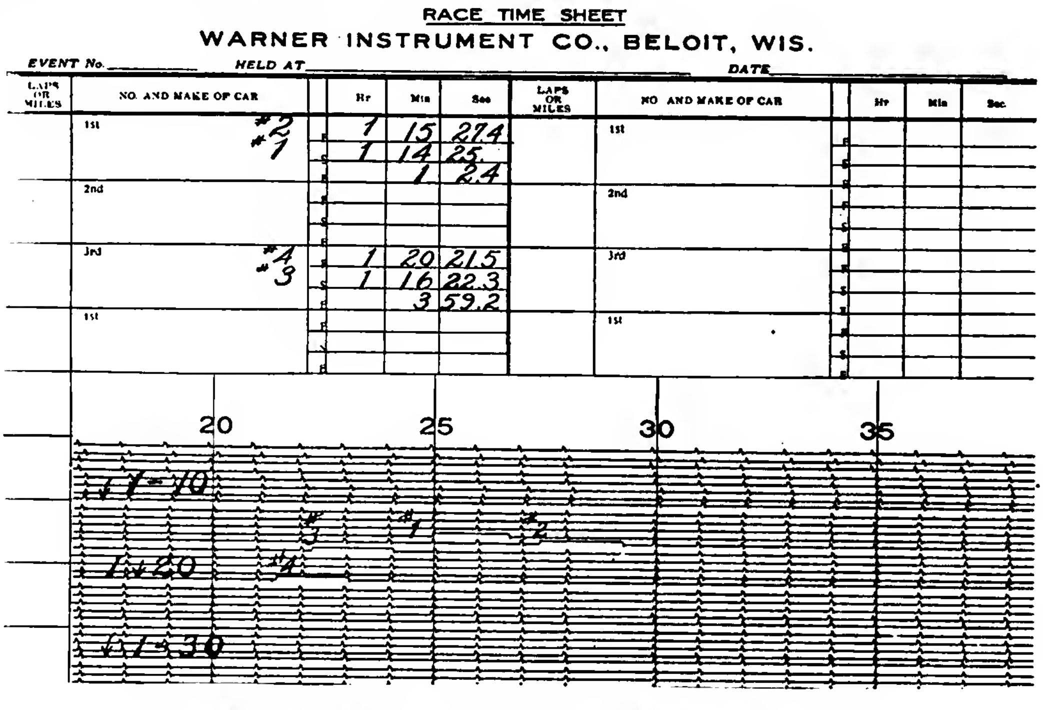
The Warner timing instrument consists of a revolving drum covered with a suitably ruled sheet of paper, on which a pen traces a spiral line. By means of an electrical connection with a wire stretched across the track the pen is jerked to one side whenever a car passes. The drum makes one revolution per minute, and the paper on it is ruled to mark every five seconds. In addition to this, the pen is connected with the clockwork so as to make a notch in its line every second. Every ten minutes, or ten revolutions, an extra wide space is left between the spiral lines, to minimize the possibility of a mistake in counting them. The wire across the track is not always connected with the device, but is put in circuit by a key handled by the operator whenever a car is seen approaching. This prevents any accidental tripping of the pen by the officials on the track.

Evidently, such an instrument can give an absolutely automatic record of the passages of a single car, as when a record trial is being made. In an ordinary race, as there are a number of cars on the track, and each acts on the recording pen in the same manner, it is necessary that the operator of the instrument mark on the record the number of the car that caused each movement of the pen. In practice two men are required to do the timing—one to operate the instrument, and the other to make the necessary subtractions to show the time of the cars for the laps and totals. The operator usually calls out the number of each approaching car at the same time that he presses the key to put in circuit the wire across the track. As soon as the car has passed he calls off the time as indicated by the recorder. The second man enters the number of the car and the time on a sheet provided for that purpose. and then figures the elapsed time of that car and its time for the last lap. These figures are then posted on the scoreboard.

When it is desired to take a record of the passage of a car at a distant point, another wire is strung across the track at that point and put in electrical connection with the instrument. The operator at this point has a key to put his wire in circuit, and also has a telephone connection with the head operator at the instrument, by which he announces the numbers of the cars that pass. These are inscribed on the record, with some distinguishing mark to show at what point they were taken.

Such an instrument is naturally capable of any desired degree of accuracy, as the recording pen moves at identically the same instant that the front wheels of the car press the wire. In the Warner device now in use the maker has been content with reading tenths of seconds. It will be remembered that the pen makes a small notch in the line every second; the distance from the nearest second notch to the deep notch showing the passage of a car is measured by a special scale to give a reading in tenths. The time could be measured in hundredths of a second, if it were desired, by using a larger drum and a finer scale with which to read the fractions. The paper record is preserved, and in case of a dispute or a mistake in posting the figures, provides an accurate record of just what actually took place. The whole instrument is as nearly as possible free from any possibility of human error.

In practice the Warner timing device has met with the greatest success, and in every contest in which it has been used its record has been accepted as final.



Specially Ruled Paper on Which the Timing Device's Record Is Made

VARYING COMPRESSION

Editor THE AUTOMOBILE:

[2,046]—I have a compressometer with a maximum hand for testing compression in cylinders of my six-cylinder car, 4¾ x 4¾. My six cylinders register as follows:

No. 4	58 lbs.
No. 6	58 lbs.
No. 5	60 lbs.
No. 2	60 lbs.
No. 3	48 lbs.
No. 1	82 lbs.

Now you will note that the compression in No. 1 registers nearly twice as high as No. 3, and, as far as I am able to judge, the piston rings and valves in both cylinders are equally tight. How would you account for the difference in compression, and do you think if all the cylinders were equally tight that the compression in each one should be as high as the highest, viz., 82? Also would the engine be more efficient if they were all as high as 82? I might say that if they were it would be very difficult to start the engine, as it is very hard now to start on No. 1.

AMATEUR.

Toronto, Can.

Such a large difference as your measuring device shows would lead one to question if it were right, since, as you say, the motor runs well. This latter would seem out of the question were existing differences as great as those between cylinders one and three above. So before going any further it would be well to have the instrument inspected and then make another trial as a check.

Granting that you find the instrument right, so that the figures given are reliable, it would seem as if the average pressure which the manufacturer intended to attain was 60 pounds. You will note in looking over the figures that, taking this as correct, but two cylinders, one and three, differ markedly from it. In fact, you could hardly expect to get and retain a closer agreement than that which cylinders 2, 4, 5 and 6 afford to this supposition.

Where the compression is high, as in the case of cylinder 1, some material will have to be removed from the piston head, combustion chamber walls, valve and valve caps, or some combination of two or more of them. In the ordinary case, the changing of the last is not advisable, so there remains but the piston, cylinder walls, or both. To reduce the piston head is the easiest, since it is done by taking out the offending piston, chucking it carefully in a lathe and turning off the required amount of metal. Figuring this out as carefully as possible, it appears as if the cylinder in question has over 8 cubic inches of space too little. That is, it lacks that much of being right for 60 pounds compression. This, based on a 4 3/4-inch diameter of piston, would mean a vertical height of 15/32 inch, nearly 1/2 inch, which you could not machine off with safety. The best plan will be to caliper the piston and see how much it will stand. Then take off that amount and see what effect it has had upon the compression. Then, if more is required, the rest will have to be taken off of the top of the cylinder walls, a hard task at best.

If you really attempt to fix the cylinders it will be well to attend to cylinder No. 3 at the same time, since that is an ever-present source of lost power. Figures appear to show this too large by the amount of over 7 1/2 cubic inches, which is equivalent to 7/16-inch height by 4 3/4-inch diameter. To remedy cylinder No. 3, then, you would add a plate to the piston head of the full diameter and 7/16-inch high, or, if the edges were tapered off, the height would have to be increased to correspond. In this latter case, see the article, "Ingenuity in the Making of Repairs," on pages 353, 354 and 355 of the August 26 issue of THE AUTOMOBILE. Upon the last page of this in particular is described the method of adding to the head of a piston, although the article is written from the standpoint of repairing a broken piston head.

The compression must be equal in all six cylinders, else the lessened amount of power developed in the one with lower compression will prove a drag upon the others. Similarly, increased power from any one would destroy the balance, which the six-cylinder is noted for, and which is the real reason for using it. If you are doubtful about your ability to fix it, or that of the nearest repair shop, communicate with the manufacturer of the car.

TO CURE BALKY STARTER

Editor THE AUTOMOBILE:

[2,047]—We have a ***** 1907 automobile that is very hard to start at first. After it has been started and has run five or ten minutes it is easy to start, if stopped. After it has run for a couple of hours it is awfully hard to start. The spark is good and we cannot adjust the carbureter so as to improve the starting.

HAYNES & SON.

Newkirk, Okla.

It is foolish to continue to crank a motor for five or six turns. In medium weather the modern engine should start on the first, or, at most, the second turn of the crank. If it does not do so, something is at fault, and should be corrected before cranking again. If the carbureter is adjusted perfectly and still the engine won't start, you should overhaul the ignition and wiring for something wrong. Look particularly for loose terminals, wires with the insulation worn off in spots, and similar small and hard-to-find sources of trouble. It sounds a lot like the second, insulation worn off. Many times this happens and does no harm when standing still or running slowly, so that the vibration is small. On the other hand, when running fast or when the vibration is very great, the bare spot rubs against metal or other conductors, with the result a short circuit. When the car stops, the bare spot pulls away from the metal, and the car will start at the first turn of the crank. Look the car over carefully for some little hidden trouble like this.

STORAGE BATTERY QUERIES

Editor THE AUTOMOBILE:

[2,048]—Will you please answer the following questions for me?

1. Can a storage battery be charged from a magneto, and if so, how?
2. Can a storage battery be charged from any source of direct current without using any additional device?

New York City. PERCY HEINEMAN.

Both questions cannot be answered directly; that is, by means of a simple yes or no, although in the case of the second question we can come pretty near it.

As to the magneto, if it is of the ordinary rotating armature or rotating sleeve type, it will generate an alternating current. This cannot be used to charge the battery without a commutating device, which will convert the current into a direct one. This may be done in a number of ways; in fact, it may be done upon the magneto itself. In other words, the magneto may be so constituted as to deliver direct current. In that case, it could be used, but much care would be necessary, as the plates of the battery could be buckled and spoiled by charging too fast. You will need a combination volt and ammeter for measuring the current, as otherwise you will not know how much current you are using and are liable to spoil the battery plates before you find it out.

The direct current may be used directly, but as brought out above it is dangerous, unless you have some means of cutting down the amount of current flowing, and some means of measuring the amount of current flowing as well. In this connection, you are referred to several excellent articles on this subject which have appeared from time to time in THE AUTOMOBILE, notably: "Operation and Care of Vehicle Batteries," August 12 issue; "New Nickel Iron Battery Withstands Tests," July 15 issue; "Pointers on the Care of Vehicle Batteries," May 20 issue; "Some Further Ignition Hints," May 27 issue; "Charging Storage Batteries," July 1 issue (letter).

Nearly every one of these excellent articles lays emphasis upon the care necessary in charging storage batteries, and the precautions which are necessary to attain proper results, and nearly every one of them, brings out the points brought out above, namely, that too rapid charging will destroy the valuable plates. That is to say, a peculiar and out-of-the-ordinary method of charging is to be discouraged, in that it might go wrong, and then you would be out the price of a new set of plates, in your particular case, the price of a new storage battery, a not-inconsiderable sum. The question arises, then, is this trying of a new method worth your while?

ANSWERED AND DISCUSSED

VACUUM AIRSHIP AGAIN

Editor THE AUTOMOBILE:

[2,049]—Your comments in the September 30 issue of "The Automobile," page 562, on the vacuum airship, which was described in the August number of "Machinery," are justifiable. We ask if you have seen the following article in the September number, page 39, by Professor Forrest E. Cardullo, which shows mathematically that no structure light enough to rise in the air (if the air were exhausted from its interior) could be made of known materials and withstand the pressure of the atmosphere.

Prof. Cardullo's demonstration gives a general formula that applies to all spheres, large or small. The fact that a sphere cannot be made to withstand the pressure of the atmosphere apparently demolishes the whole project, as surely a cigar-shaped vessel would not be as strong as a sphere.

We have endeavored to get Mr. McCready to publish details of the De Bausset design, but he has not complied, and we feel that the De Bausset claims are without sound foundation.

FRED E. ROGERS,
New York City. Editor "Machinery."

The article referred to should conclusively discredit the vacuum airship idea. Prof. Cardullo takes for the sake of convenience a sphere containing one pound of air. Such a sphere would be 2.93 feet in diameter. If the sphere itself is to weigh one pound, the thickness of its wall (made of steel weighing 480 pounds per cubic foot) will be about 0.0001 inch. The atmospheric pressure on it will be 14,270 pounds; the cross section of the shell will have an area of 0.1023 square inch, and therefore the compressive stress in this cross section will be 140,000 pounds per square inch.

Even more obvious is an illustration taken from Mr. McCready's own figures. The proposed airship was to be 150 feet in diameter and 750 feet long, and was to weigh 270 tons. Prof. Cardullo says: "If all this 270 tons were utilized as a 700-foot steel column, keeping the ends of the cylinder apart against atmospheric pressure, the stress in the column would be 163,000 pounds per square inch." He also disproves another theory which has long been upheld, namely, that the vacuum ship becomes more practicable as its dimensions are increased. Prof. Cardullo shows that the compressive stress in the wall will be independent of the diameter.

This should dispel for all time the old and well-worn vacuum "chestnut." Those interested are referred to the article.

LIST OF 1908 AUTOMOBILES

Editor THE AUTOMOBILE:

[2,050]—Have you on hand any publication giving a complete list of the 1908 models of American automobiles, with detailed description, price and illustrations of each?

A. B. CRAFT.
Cranford, N. J.

Just the matter you want will be found in the November 28, 1907, issue of The Automobile, on pages 792 to 796, inclusive. This is the tabular story of the American cars for 1908, published in advance. The whole range of cars is covered, these being divided into four main classes, namely, gasoline pleasure cars, electric pleasure cars, gasoline commercial vehicles and electric commercial vehicles. The first named, in turn, is subdivided according to price classification into: cars costing less than $1,000, costing from $1,000 to $2,000, costing from $2,000 to $3,000, costing from $3,000 to $4,000, costing from $4,000 to $5,000, costing from $5,000 to $6,000, costing $6,000 up. This makes ten complete and separate lists, which include no less than 400 cars. As for illustrations, you will find a few in that and succeeding issues. We know of no other publication which will give you as good or as complete a list as this one.

PLATINUM POINTS BLACKEN

Editor THE AUTOMOBILE:

[2,051]—What is the cause of an induction coil on a two-cylinder automobile becoming blackened (apparently oxidized) on the platinum sparker at contact point? Three new points have been tried with the same result; when they become blackened the sparker fails to work unless it is taken out and polished, when it is all right for a few hours, then the polishing has to be repeated The other coil never bothers in this way at all.

T. NELSON & SONS.
New York City.

This is a trouble which we have never heard of before, and are inclined to believe must have misled you. This is, the ordinary pitting of the platinum points of a coil is accompanied by more or less blackening of the metal. We are inclined to think that you have confused the real cause of the trouble (pitting) with one of the results (blackening). Some pitting is to be expected, and no method is known of absolutely preventing it but by having a proper adjustment of the points, so that too much current (and, consequently, heat, which means pitting) will not pass through the points. One way out of the trouble is to get a specially made two-cylinder coil, with but one trembler. This will reduce the platinum point trouble to a minimum, in that it gives but one point to be kept in good order. In polishing off corroded or pitted points, use the finest file obtainable or the very finest emery paper. In a recent issue you will find Nicholson's X F Number 6 Swiss file advocated as excellent for this. The use of even this, to say nothing of the heavier and coarser files, should have much care, from the viewpoint of the tremendously high value of platinum, even the small amount filed off having a value.

GARAGE FLOOR MATERIAL

Editor THE AUTOMOBILE:

[2,052]—In one of the early summer issues of "The Automobile" the address of a firm supplying a plastic material to be applied over old garage floors, to render them impervious to water, etc., was given. I cannot now find that number. Can you help me?

H. G. A.
Waterbury, Conn.

The substance to which you have reference is called Crown Sanitary Flooring. It is made in New York City, by Robert S. Keasbey Company, 102 N. Moore street. It was described in the July 15, 1909, issue of The Automobile. For the benefit of those who are interested in this material for garage use, and who missed that particular issue, a short description of it may not go amiss.

It is said to be an asbestos composition, and comes in the form of a paste. This may be applied to an old or new floor in any convenient manner, spread over in an even layer. The makers recommend a thickness of 1/2 inch in the ordinary case. Besides the advantage of being easily and quickly applied, it has the merit of being water, fire, and oil proof. It may be had in any desired color, from the method of laying it would have no seams, and similarly, when finished it will be practically indestructible. With this large number of features to recommend it, it should find wide use.

LIGHT STAND FOR GARAGES

Editor THE AUTOMOBILE:

[2,053]—Sometime during the summer I saw an article in "The Automobile" about a device for supporting electric lamps in the garage, in such a way that a chauffeur could work by them at night. It was a stand, and the lamps were hung on it in such a way that a person could move the stand anywhere. As I remember, it was quite light in weight. I cannot find the number of the paper in which it was described, and would like to have you let me know about it.

R. M. BURNETT.
Southborough, Mass.

The article in question will be found in the July 1 issue of The Automobile, under the heading, "Saves Electric Light Bills." The stand is there described in full. It is there called the Portland Wash Rack Stand, which is a misnomer, for the right name is the Portable Wash Rack Stand. It is made and marketed by the Brown Company, Syracuse, N. Y. As you say, a device of this sort is very convenient in and around a garage. Its lightness, compactness and low price render it a valuable thing in any sort of a shop.

ATTENTION MANUFACTURERS

Editor THE AUTOMOBILE:

[2,054]—I would like to contribute a short article to your publication with a view toward attracting attention of automobile manufacturers to the advantage of establishing branch factories in the Southern States, where the demand for motor cars is beginning to assume prodigious proportions. The stimulation that has recently been given good road construction has had remarkable effect upon the motor industry, and it is but a question of a short time when all kinds of motor vehicles will be in great demand, from the gasoline plow to the high-priced and luxurious limousine.

It is not fair nor is it logical that a greater portion of fine grade cars should be constructed north of Mason and Dixon's line, for it forces the southern purchaser to go into his pockets for the enormous freight rates or charges that unjustly add so much to the initial cost of his car.

We should have home factories to supply the home trade, and it is up to the progressive motor car builder to realize that the first on the ground in this promising, and well nigh virgin field, will reap the greatest harvest. The southern people are clannish and are loyal to "home industries," and would greatly prefer purchasing a high-grade car of home make to one built in another section of the country, especially so when they keep the $25 to $100 in their pockets that they are now forced to pay the transportation companies before their motor car can be delivered.

Now it is well known that within this part of Georgia there can be found abundance of raw materisl for motor car construction, and thousands upon thousands of hydraulic horsepower, in the present form of small streams, flow through the richly timbered and ore-imbedded hills of old Georgia, idly to the sea, that could be harnessed and made to furnish power for manufacturing enterprises at less than half the cost of artificial energy developed by costly boilers, engines and constantly increasing expensive coal.

Within this, Bartow County, Georgia, are found practically inexhaustible deposits of iron, manganese and asbestos. Beauxite also abounds, corundum, some lead and great quantities of the finest grade of yellow ochre. Hardwood timber of all kinds and pine of the best quality grows upon the hillsides.

I have no property to sell, nor have the slightest interest in any real estate or property of any description that could gain from the installation of an automobile plant in this section, but my patriotism for my city and county, and my desire to see the development of marvelous natural advantages, prompts me to make some effort to draw attention to the advantages to be found here by some progressive manufacturer.

The United States Government has a corps of surveyors now examining a site upon the Etowah River, four miles from this city, where between two gigantic bluffs a dam 190 feet high, which will develop more than 20,000 horsepower, will soon be built by Uncle Sam. This power will be for sale at low rates. The dam will back water over a length of 18 or 20 miles and will make an artificial lake that will rival in scenic beauty the famous Lage George, N. Y., and will make a new field for motor boats, as well as furnish a fine location for a factory for the construction of such pleasure craft.

It will be a big thing, and I would like to get it before the manufacturers, in order that they might investigate when they come to Georgia to attend the show and races during November in Atlanta.

S. P. JONES, JR.,
Advertising Committee,
Chamber of Commerce.

Cartersville, Ga.

SELF-STARTER INFORMATION

Editor THE AUTOMOBILE:

[2,055]—Will you kindly give me an article on the various schemes or contrivances for automatically starting gasoline engines or automobiles. The various methods employed, and the success or failure of the same? What were the reasons for any trouble that developed? I think that an article on this subject would be interesting to others as well as myself. W. T. K.

Nichols, Conn.

If you will turn back to Volume 20 of THE AUTOMOBILE, which you doubtless keep on file, you will find, in the April 1 issue, the very thing that you are looking for. This is an article entitled "Self-Starting Devices Attract Much Attention," and in so far as it was possible in three pages (542, 543 and 544) the whole subject of starters was covered. They divide naturally, as the article points out, into two classes, the mechanically operated and the fluid operated. In the former class are the strap, spring and similar devices, while under the latter head are grouped the compressed gas, compressed air, exhaust gas, and similar starters. You will find these described in the article mentioned.

RULE OF THE ROAD

Editor THE AUTOMOBILE:

[2,056]—Attached find photographic drawing explaining collision which occurred some two or three weeks ago.

The Green car coming up Broadway on the correct side of the road intended to turn into the Little Neck Road on a close turn (This is a notoriously bad turn). The Green car was traveling slowly on account of the chauffeur's knowledge on the bad turn and the condition of the road. The Yellow car was coming down Broadway in the center of the road. The Orange car was on the wrong side of the road, and seeing the Green car about to make the turn, applied his brakes. The chauffeur of the Green car also applied his brakes, but skidded into the Orange car, breaking a wheel on the latter. At this time the Blue car was in the center of Little Neck Road. The owner of the Orange car (which was on the wrong side of the road) sent a bill for damages to the chauffeur of the Green car. The latter had adhered to the rules of the road and kept to the right. Kindly state who is at fault.

COLLISION.

New York City.

Not being able to reproduce colors, it will be necessary to letter the cars. On the diagram of the two roads and the cars involved, as brought out above, everything is just as the original diagram showed, except that the green car has been marked A, the orange car B, the yellow car C and the blue car D.

Green car A was in the right, and therefore not to blame, and should not pay the damages asked. Orange car B, being in the wrong, should suffer whatever damages were inflicted as a penalty for not obeying the laws of the road. Yellow car C and blue car D have no actual connection with the case, as from your letter we take it that both of them were at some distance when the collision started and came up later on. They may, then, be eliminated from the case.

The proper method of procedure for orange B car would have been to slow down and apply brakes before actually reaching the turn and before he saw green car A. This was his necessity because he was in the wrong—"off side," to use a football term. In that case he would have had his car slowed down before he saw green car A, and as soon as he sighted the latter it would have been an easy matter to stop in time to avoid an accident.

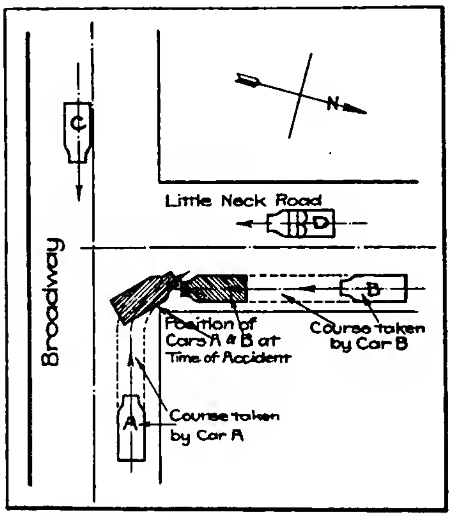


Diagram of Collision on Long Island

It is very plain that green car A was not at fault, and, as stated above, he should not pay any part of the damages incurred by another car which did not observe the law. The submitting of a bill by the latter was not at all surprising, as the road hog, who habitually uses the most convenient side of the road, regardless of others, is usually equally inconsiderate in laying the blame for an accident.

TO ELIMINATE KNOCKING

Editor THE AUTOMOBILE:

[2,057]—I have a suggestion for E. W. Kafer letter (2,037), whose mysterious knocking troubles are exploited in the Oct. 7 issue of "The Automobile." It is just barely possible that one of the valve tappet rods has become so worn in its guide that it has some side play; if this be the case, high motor speeds with well-opened throttle bring out the knock, as there is considerably greater pressure upon the valve, under such circumstances. This increased pressure resists the raising of the exhaust valve and therefore the tappet. The latter being urged by the cam, strikes the worn side of the guide a very hard blow in its endeavor to shirk its natural function. At least, this proved to be the solution of a very baffling knock in a car I owned, which, before I located it, caused me to tear down the motor completely five successive times only to find everything apparently beyond criticism.

K. R. MANVILLE.

New York City.

While the writer of the letter referred to in the above communication did not bring out the point that the trouble only disclosed itself at high speed, as Mr. Manville seems to think, the suggestion is a very good one, and Mr. Kafer's attention is called to it, as well as all motorists, who have, at one time or another, had trouble with a peculiar pounding which defied exact location, and which was omnipresent. It is the little troubles like this, which frequently pass by the notice of the shop or garage "expert," which every amateur is anxious to know. These little things cannot be "doped" out sitting in a comfortable office chair, but must come from actual, and sometimes painful, experience.

MAKE AND BREAK PLUGS

Editor THE AUTOMOBILE:

[2,058]—Will you kindly advise me where I can secure make and break spark plugs to work from a General Electric Company's magneto, made to use with make and break spark, that is, low tension. W. M. CASE.

Clarksville, Tenn.

By far the best way to obtain these plugs, if the makers of the magneto, the General Electric Company, Schenectady, N. Y., will not assist you, will be to go to companies now using, or which have used in the past this form of ignition. These companies will doubtless be glad to sell you an outfit, which you could use with a little adaptation. As a matter of fact, no such plugs have ever been manufactured for sale, each company using this system making its own plugs. Companies which now use or have used this system are: Locomobile Company of America, Bridgeport, Conn.; Gaeth Automobile Gompany, Cleveland; Studebaker Automobile Company, South Bend, Ind.; Ranier Company, Saginaw, Mich.

Fig. 1—Model D, regular $485 car, equipped with oil lamps, tools, tire kit, etc., and ready to run

SOMETHING of a sensation was experienced when the Brush first came into being, primarily because the price was low, relatively, and novelty was written all over the car. That merit also was a comparison seems to be borne out by the last year's performance, of which there are now so many cars in use that it is extremely difficult to stand on any prominent corner in Detroit for ten minutes during the day and not see one go by.

Under the circumstances it would seem as if it will be well worth the undertaking to investigate the car at some pains and ascertain just how it is made and try to tell why the maker deems it expedient to enlarge the line and turn out a vast number of the cars during 1910.

The prime idea of the Brush Runabout Company, of Detroit, Mich., is to make a standard chassis which will be available for use under a great variety of conditions and Fig. 2, representing a coupé, shows up one of the uses to which the chassis may be put to excellent advantage. Among the other selections, of which there will be eight all told, model D is the regular car, which represents a runabout type, as shown in Fig. 1, at the very modest price of $485. The remaining selections include a car with an ornamental tool box at the rear, another with a rumble seat and a third, in raceabout style, with an oval gasoline tank back of the seat of a capacity for a day's run.

The Brush from a Mechanical Point of View—The chassis frame is of wood, the reasons for which, according to the designer, is to afford lightness with strength and to attain a certain degree of flexibility and other qualities attributed to resilience. This is not a new idea, it being standard on such cars as Franklin, Panhard, etc.

The spring suspension is at variance with common practice, in that the chassis frame rests on helical springs placed just over the axles at the four points of suspension, and in order to induce a slow rate of vertical bounce following road inequalities attended by speed of the car, the distance rods are terminated at the chassis frame for the front and hind axle at both sides in friction disk members, so contrived that the friction set-up, due to vertical motion of the axles, will be enough to assure that the travel of the body in the vertical direction will be gradually snubbed and the rate of change of motion will be that described as agreeable riding qualities.

Some earlier attempts to use helical springs for chassis suspensions failed to come up to the expectations of designers, primarily because the snubbing action of the friction members was not taken advantage of and the axles were very heavy indeed, considering the things to be accomplished. The Brush plan does not end with placing friction members to limit vertical bounce, for the axles are made of wood in order that they will not be heavy, although it is recognized that they must be strong.

At first thought it might be considered that axles of wood in an automobile is an innovation not to be taken seriously. Let us have another look. These axles weigh but a few pounds; regular live rear axles weigh nearly 200 pounds. The difference is the story of energy of impact and the influences of acceleration. Were the axles heavy, as they would have to be were they made of metal in the usual way, there is small chance that the friction members on the ends of the distance rods would be capable of snubbing the motion of the rapidly bouncing axle at high rates of road speed and with rough going.

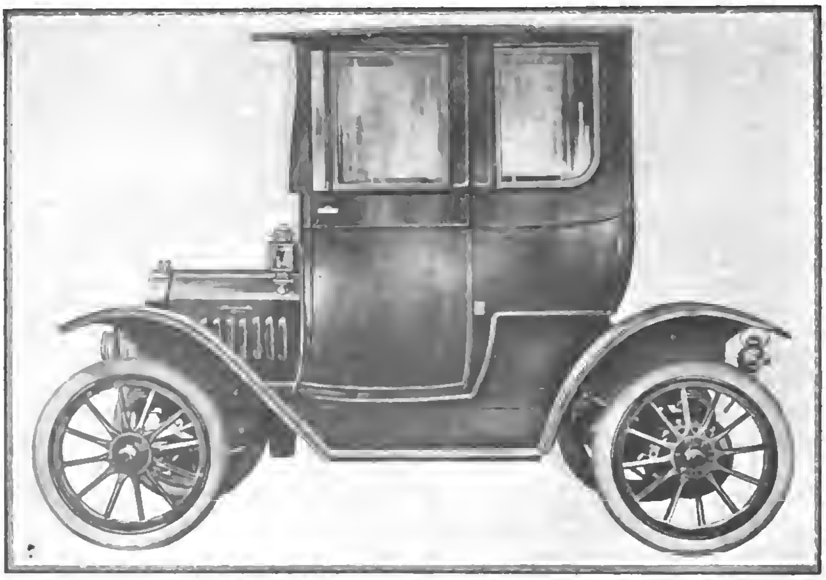

Fig. 2—Brush chassis, equipped with coupé body

By making the axles so that they weigh but little, the featherweight impact component is not enough to overcome the "damping" ability of the shock absorbers, and the body rides on an even platform even when the speed of the car is quite high and when road inequalities are pronounced. There is one point in favor of helical springs aside from the fact that they are practically unbreakable, and that is, they are capable of recovering at a more

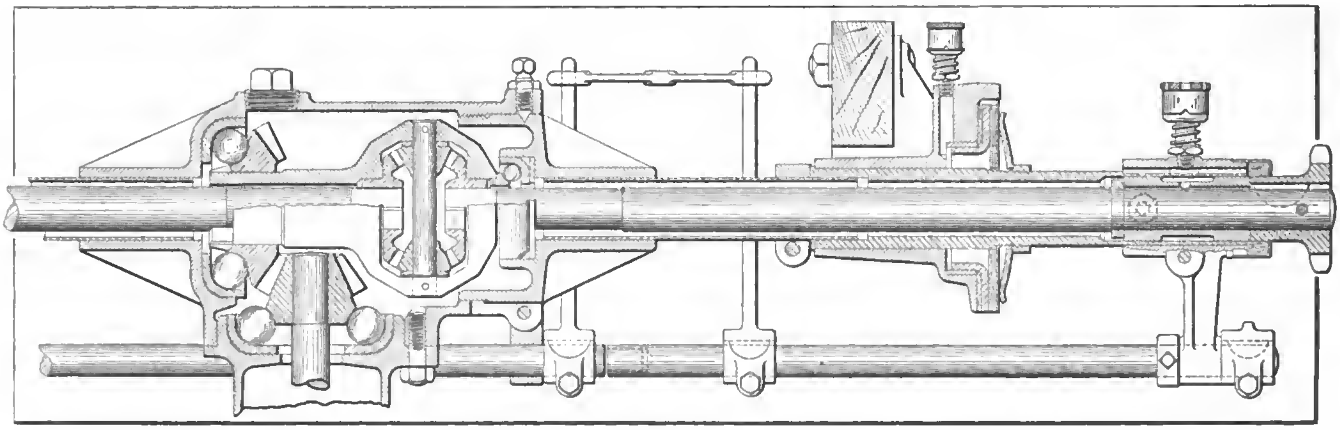

Fig. 3—Depicting jackshaft in section with differential and large ball bearings for the bevel drive

than usual rate when a wheel drops into a rut, and the general performance is very satisfactory, simply because the weight of axle is not enough to disturb the otherwise good relation. As to the strength of wooden axles, it is not necessary to go into detail; they were used in every wagon in the land before steel came into vogue, and the history of wagons does not disclose that they failed in any particular. Four thousand Brush cars add to this favorable historical fact, and this phase of the discussion may therefore be dismissed as being too trivial to warrant the taking of time and space.

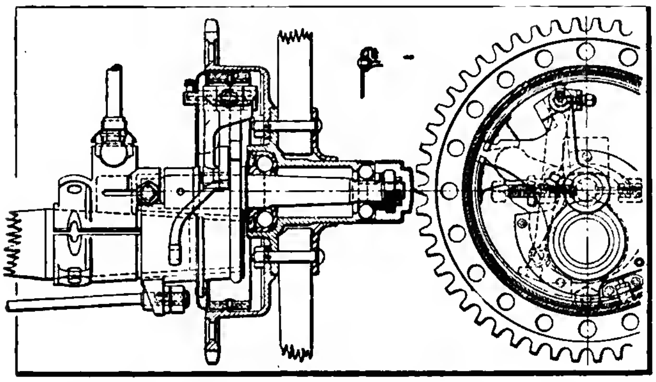

Fig. 4—Rear wheel, sprockets, brakedrum, showing ball bearings, and system of protection against silt of the road

Belongs to the Side Chain Drive Genera—Referring to Fig. 3, of the jackshaft, which is placed across the chassis frame in front of the hind axle a sufficient distance to allow of the required length of sprocket chains, of which two are used, placed as is the custom in cars in general. The differential gearset is shown in section and the cup and cone ball bearing to one side of the housing take the load at this point. The bevel drive also shows on the end of the differential sleeve, engaging the driving pinion on the end of the propeller shaft. leading from the motor through the transmission gearset.

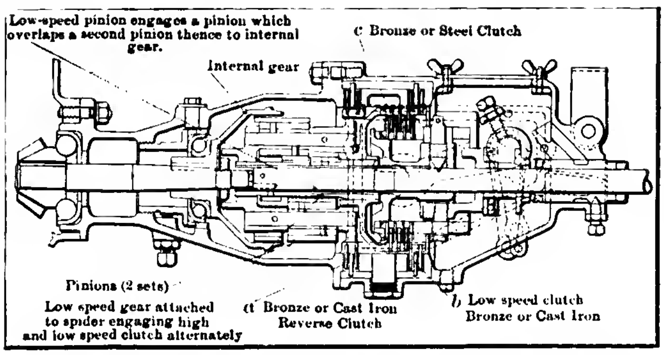

Fig. 5—Planetary gear set, showing multiple disc clutches, system of gears, and screw system of engaging the high speed

The large ball bearings used to back up the bevel drive are excellent indications of the plan of the designer, and, as will be well appreciated, the larger the balls are the longer they will last under thrust and high-speed conditions, which is the reason for the large balls used. The material of which the bevel gears are made is that which will best stand cementation and the finished gears are capable of serving for ball races of competence as well as for the regular work of transmitting power.

The remaining features of the jackshaft will require no more than a glance to disclose the character of the design and workmanship, and grease cups are placed at all points for the customary purpose and with the further idea that as grease oozes out silt of the road will not be creeping in.

Fig. 4 is a section of the rear axle, showing how the sprockets are fastened to the rear wheels by engagement at the bolting of the hub flanges, using the regular hub bolts for holding, and the brake drums are integral with the sprocket wheels. The brake shoes are of adequate stiffness, remembering that they are of the internal expanding type and have to be stiff to properly work, while the facings are wide, of material which affords a high coefficient of friction, and the means of applying pressure show competence. The brakes are inclosed and the dust cover is so contrived that it serves its purpose admirably.

The distance rods fasten to the rear axle just under the spring perches as shown, and a ball and socket (universal) joint, using large diameter ball for the purpose, takes the work, eliminates noise and may be adjusted at will. The wheels are fitted with 28 x 3 1-2-inch pneumatics and the cup and cone ball bearings are even large for the purpose. One other point before departing from the rear axle design; the means for adjusting the wheels to the bearings includes a large hub nut, castellated so that it can be locked when the adjustment is properly made, and closures are placed to keep grease in the cavity as well as to keep silt out.

Transmission Possesses Novel Features—The transmission is of the planetary type, giving two speeds and reverse. Like all planetary gears, when it is desired to go at high speed a clutch is interposed to lock the gears so that the whole nest rotates and the drive is that known as "direct on high"; to go into low, or reverse, the usual custom is to hold the drum by means of friction bands, which may be tightened at will. In the Brush multiple disk clutching members are used in the three cases, bands are eliminated and the ability of the low and reverse clutches is equal to the requirements as measured in this way. The clutch for the high speed (direct on high) differs again from clutches in general in that the means of engaging is novel and is claimed to possess certain specific advantages. The section Fig. 5 shows the general arrangement, in which will be found the high-speed clutch, consisting of disks resting between vise-like jaws, one of which is formed out of the spider and the other is in concentric relation, sufficiently spaced in the axle plane to afford room for the disks plus clearance when the clutch is not engaged.

When it is desired to engage the high-speed clutch, movement of the lever results in the closing of the vise on the disks, as follows: Through the compound action of a screw, which is thrown into engagement by the lever system, the original effort of the operator is added to by the torque of the screw, transposing the torque of the motor. All the operator has to do is to make the initial effort and the pressure resulting is enough to bring the screw into action, when the torque of the motor will wind up the screw and tighten the clutch, all without the use of a heavy spring and at the expense of a minimum effort on the part of the operator, while, at the same time, the engagement is not only gradual, but positive.

The screw effect is brought about by so shaping the metal sleeve so that rollers, which protrude into spiral slots in the sleeve, will screw the sleeve into engagement once the initial motion is imparted by the operator. In disengaging the clutch the reverse action follows and the disengagement is positive and quick.

The planetary, as shown, belongs to the internal gear type, is therefore free from noise when well made, and the low-speed pinion on the shaft, when going into reverse, transmits its motion through overlapping, intermediates, of which there are two pairs, thus making the mechanical balance perfect and assuring adequacy of mechanical ability without having to use large members attended by noise, inertia effects, etc.

The low-speed gear which is attached to a spider is free to engage either the high or low-speed clutch at will, thus perfecting the device for the purpose. The whole system is properly inclosed, may be packed with grease, is so simple to operate that skill is not required and to make a wrong move is quite out of the question, even in the absence of knowledge.

Novelty Resides in the Motor—The single-cylinder motor is rated at 10 horsepower and is of the vertical type placed in front, as in foreign practice. The power of the motor is greater by 3 horsepower than that of the last year's product, not so much due to any very great demand, but, as the designer put it, so that drivers will feel the excess and worry will then be out of a job. The cylinder is of the L type, as depicted in Fig. 6, and among the advantages symmetry has a claim. The head is screwed in against a bevel seat, is rendered tight by the pressure of the head cover against the seat and is readily removed at will if it becomes necessary to clean out the combustion chamber space, as when carbon forms. The valves are large, press against bevel seats, are properly water-jacketed, and, by means of adjustments at the terminals of the tappets, timing may be accomplished to a nicety at any time.

The crankshaft, as shown in Fig. 8, is of 40 points carbon open-hearth steel, stout of section and balanced. Even when balanced to a nicety a crankshaft in a single-cylinder motor cannot be free from unbalanced secondary moments, and it is in this particular that the 1910 Brush offers a new innovation. Fig. 7 shows a balanced gear which meshes with a gear of the same diameter on the crankshaft. The balance weight in the gear Fig. 7, in a plane parallel to the balance weight on the crankshaft, and since the crankshaft balance takes care of all unequal rotary moments plus one-half of the unbalanced secondary moments, it remains for the auxiliary balance (balanced gear) to cope with the remaining unbalanced secondary moments.

The secondary balance rotates on an axis above the axis of the crankshaft a distance sufficient to compensate for angularity of the connecting rod, and while it is not claimed that this sec-

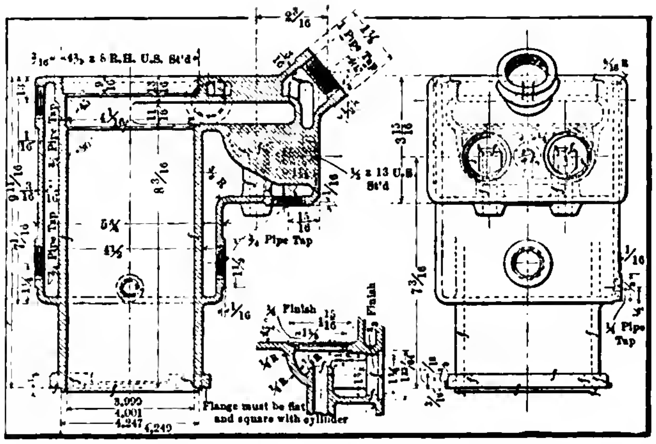

Fig. 6—Cylinder of gray iron, with screwed in head, bevel seat to make it tight, and valves at one side

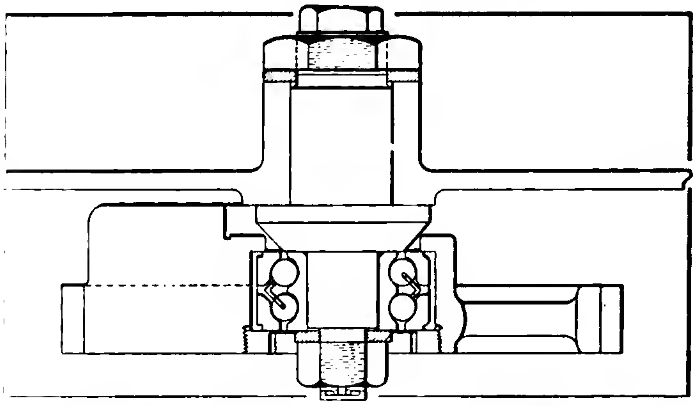

Fig. 7—Auxiliary balance gear showing New Departure ball bearing and eccentric spindle with adjusting nut outside

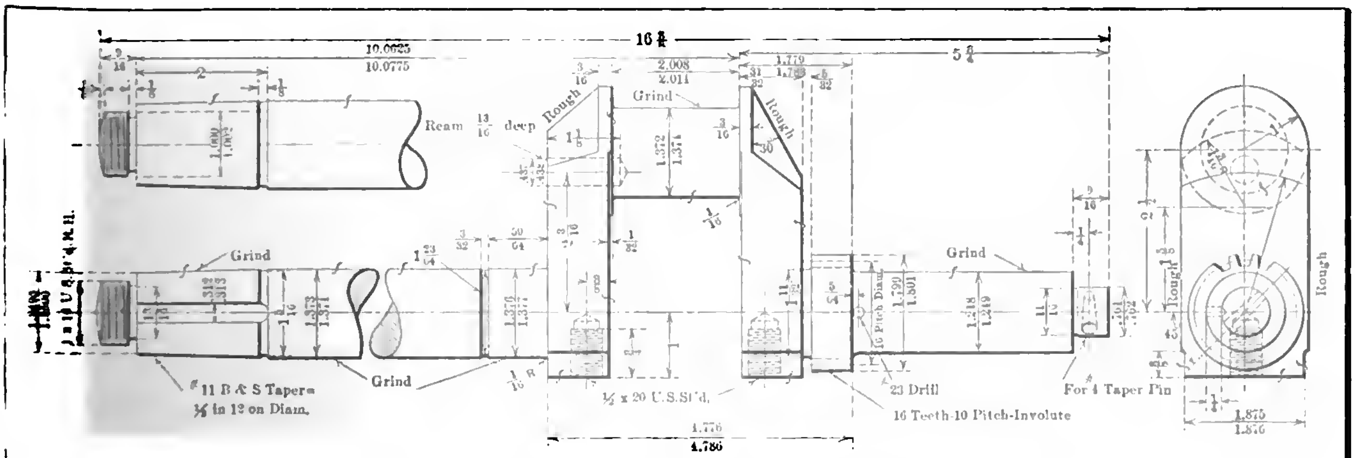

Fig. 8—Crankshaft of 40-point carbon open hearth steel, with liberal bearings surfaces, stout arms and means of direct and auxiliary balancing by thorough use of an auxiliary balance gear

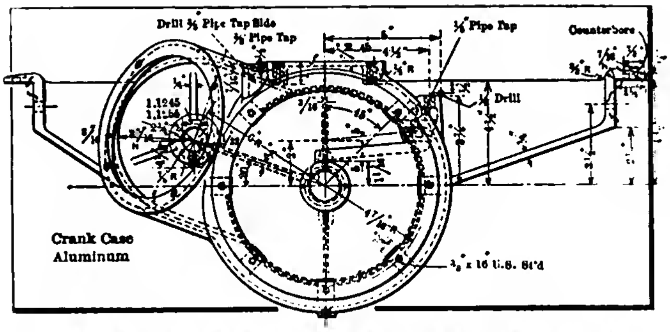

Fig. 9—Crankcase showing opening for balance gear, arms for supporting, and general design

ondary balance is capable of perfection in the sense that the ills of all secondary movements will be dispelled, even so it is the fair claim of the makers that a four-cylinder smoothness accompanies single-cylinder simplicity, and the performance of the motor seems to be the proof of the pudding.

The bore of the cylinder being 4 1-2 inches and accompanied by a longer stroke than formerly (5 inches for 1910), the power is vastly increased over what might have been the normal expectation, since the balance is sufficiently corrected to allow of running the motor at the higher speeds for which four-cylinder motors are adapted, and more power results.

This auxiliary balance is a new idea in American motor practice and in view of the revival of the single-cylinder motor, due to its simplicity and economy, it is reasonable to expect that the auxiliary balancing idea will have a large influence on the future of this situation. It was expected that the balance gear would introduce noise to some extent, which was the theoretical objection to its use, but the quality of work done in the Brush shop seems to be proof against this tendency.

The introduction of the balance gear makes the aluminum crankcase of the motor look as depicted in Fig. 9, looking at it from the end opposite the flywheel, and the opening to the left is that through which the balance gear is passed in assembling or examined thereafter at will.

Fig. 10 represents the steering gear, in which the reduction ratio is 6:1 and the performance is that of a well-thought-out device. The ball on the end of the steering lever is 1 inch in diameter and means are provided to take up lost motion if time makes inroads on the hardened cups which encircle the ball. The gear is rigidly supported to abort possible lost motion from this cause and the sleeves bearing leading to the gearset is long.

An inspection of the material and the way the cars and parts are worked up in the shop leads to the conclusion that a well-thought-out shop system is at the bottom of much of it, and it must be remembered that, while the Brush car is still young, it is built under the "watchful eye" of the responsible head of the Briscoe Manufacturing Company in a well-equipped plant which dates back into automobile history. This plant is primarily devoted to the manufacture of radiators, and is fitted out to do this and other accessory work on a large scale. The machine shop, for illustration, is modern, holds in its makeup a fine assortment of special machine tools of the most modern description, and the force of men available is large and skilled in automobile work. It is for this reason that the Brush car has been brought to a high plane and a large number put on the road, despite the fact that the new plant in which the cars will ultimately be turned out is not ready for occupancy. The new plant will be ready for this year's work.

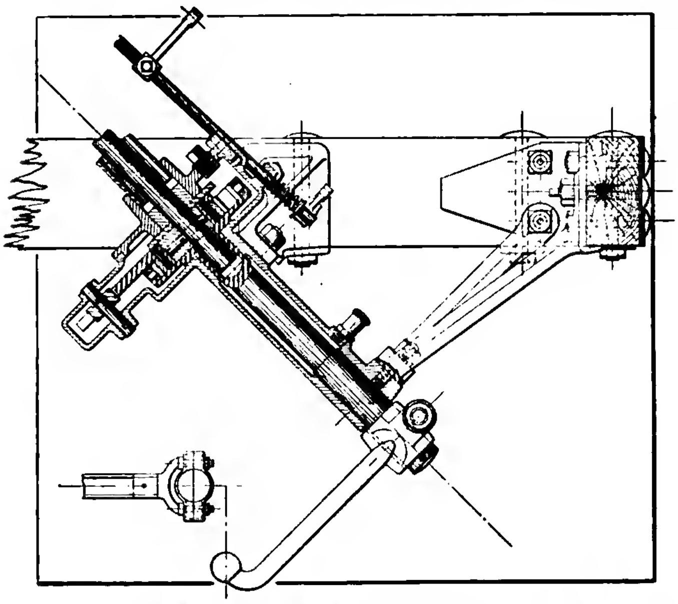

Fig. 10—Steering gear, having a 6 : 1 ratio, long bearings, and strong support to frame

ACCOMPLISHMENT OF ENGINEERS

The remarkable demands made on automobile engineers and the astonishing way in which these demands have been answered have produced the high-priced car of to-day. It is a wonderful creation and there is not a standard car made that is not worth more than is charged for it. At the same time to stand at any populous thoroughfare and see the hundreds of $2,000 to $5,000 vehicles rushing past carrying one or two persons makes one feel that we are living in an age of Babylonian luxuriousness.

Frank Briscoe

In recent times the medium-priced cars have been developed and sprung into favor, taking advantage of the skill and experience in the more luxurious class. Considered as a luxury, the high-priced car is magnificent, but for the great useful demand for transportation off of rails the utility type of car is offered.

Conspicuous efforts to put out very low-priced cars failed because the makers built them crudely, considering price only of importance, whereas the real endeavor must include the lesson learned by engineers and manufacturers, whose goal was results rather than price. We have, furthermore, learned new lessons, finding that just as much accuracy and strength must be put into the smallest car built as in the more pretentious. In point of being "fool-proof" the low-priced car must excel its big prototype for obvious reasons.

The object in the Brush runabout enterprise, aside from the primary one of making money, is twofold: First, to accomplish the broadest part of the demand for simple transportation, and, second, to make purchasers of larger cars appreciate the utility of the other class and thus stimulate the business in general.

PROPER SHOCK ABSORBER ADJUSTMENT

It sometimes happens that the adjustment is not the same on both sides of a car. This may happen even when the pointers indicate the same number on the dial, due to inaccuracy in dial setting. It is a matter of skill to apply the remedy, since it involves a readjustment on the part of the driver, and he must "feel" of the car, so to speak, and in the act determine if the "drag" is the same on both sides. If there is no dial, the adjusting process will be quite the same. It is too much to expect of shock absorbers that they will serve any good end unless they are capable of offering a well-regulated drag and of responding in step with the motions of the body.

Fig. 1—Model 50 touring car depicting a roomy tonneau and wide side entrance besides good taste

THREE new four-cylinder models, all touring cars, will be included for 1910 as follows: The Model 50 at $2,200, Model 40 at $1,700 and Model 30 at $1,250. In the Model 50 the wheelbase is 122 inches, and 36 x 4 1-2-inch wheels are used. Model 40 has a 110-inch wheel base and 34 x 4-inch wheels, and Model 30 has a 105-inch wheel base and 32 x 3 1-2-inch wheels; all models are with standard tread.

Similarity of Features in Design—It has been the aim of the company to employ the same principles of design to the respective models. The motors are placed vertically, in the front of the chassis, with dimensions as follows:

Model 50, 4 3-4 x 4 3-4 inches bore and stroke respectively. cylinders cast separately, valves in the head, and superimposed camshaft, actuating large, and advantageously disposed valves, thus insuring an excellent torque characteristic and increasing power with increasing speed as per the usual expectation under such conditions. The general appearance of the motor will best be appreciated by inspecting the reproductions Figs. 2 and 3, depicting the intake and exhaust sides respectively.

Model 40, 4 1-2 x 4 1-2 inches bore and stroke respectively, cylinders cast in pairs, valves in the head, camshaft superimposed, actuating 2-inch diameter valves with a 3-8-inch lift. Fig. 4 shows this motor looking at the intake side.

Model 30, 4 x 4 inches bore and stroke respectively, cylinders cast in pairs, valves in the head, super-imposed camshaft, actuating 1 7-8-inch diameter valves with a lift of 3-8 inch, with general appearance as in Fig. 5.

Position of the Valves Considered Advantageous—Since a hemispherical head, or dome of the cylinders, affords the greatest volume per unit of area of flame swept surface, which has the advantage of increasing thermal efficiency and eliminating radiator capacity troubles, the Jackson idea includes this form of cylinder, and by placing the valves in the head as shown in the figures, but one camshaft is necessary and that is designed as a unit, so self-contained that the shaft, bearings and housings may be removed and replaced at will. Fig. 8 shows a camshaft unit separate from its motor, and the two end bearings are in place while the two middle bearings are removed; one to show how the rockerarm for the tappets and the housing may be separated, and the other shows the housing parted through the middle, disclosing very liberal bushings, which serve as bearing-brasses for the rockerarm.

Adjustments are provided for the purpose of timing the opening of the valves, and to compensate for grinding in the valves, which, however slow may be the wear, must be provided for if a motor is to give good satisfaction for a term of years. The camshaft is provided with a long sleeve bearing on either side of each cam so that there is no chance of deformation of the shaft, and precision of timing is therefore assured from this point of view. The cams dip in lubricating oil each time that they make a revolution, and the oil is spilled on to the rockerarm, down which it runs and spreads out over the rockerarm bearings as well as the surfaces of the cams, so that friction, wear, and noise are aborted.

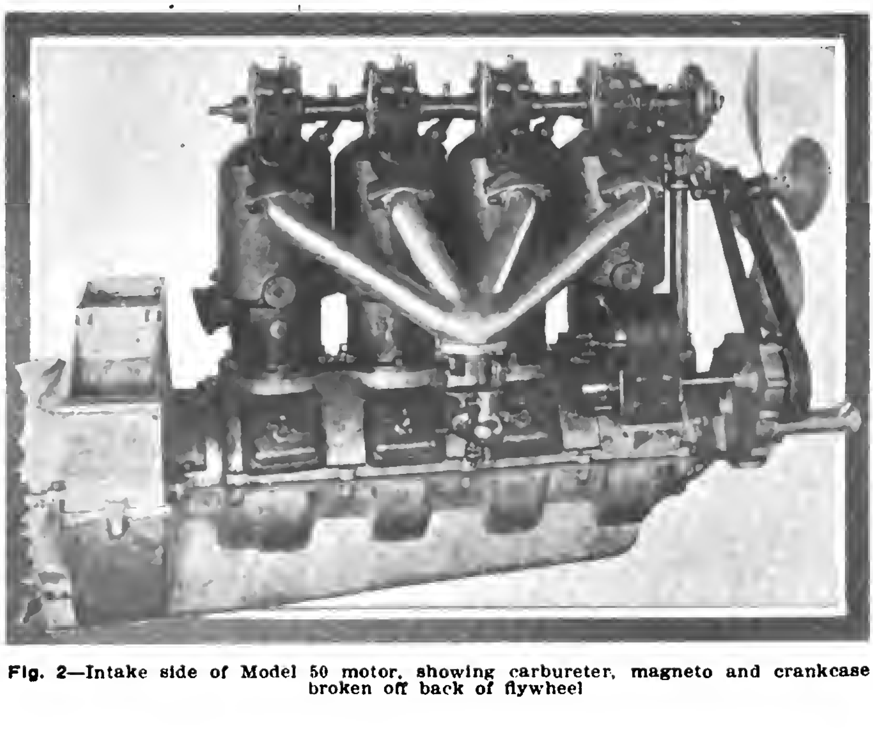

Fig. 2—Intake side of Model 50 motor, showing carbureter, magneto and crankcase broken off back of flywheel

General Characteristics of Power Plants — All three of the power plants are self-contained, suspended on three points, and include the transmission gear set in the same couple. Fig. 7 depicts the advantageous manner in which the trans-

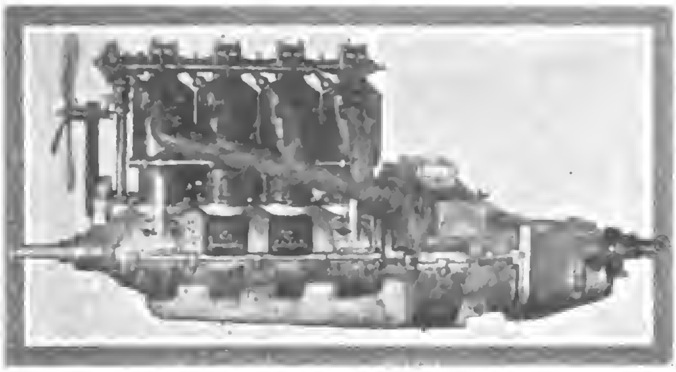

Fig. 3—Exhaust side of Model 50 motor, showing full length of crankcase, and nicely contrived exhaust manifold

mission gear and multiple disc clutch are included in a separate part of the housing, with a stout bolting flange, and referring to Fig 6, *A A A A* are wings of the discs and rotate with the flywheel with holes that register with bolts which slide into place during the process of assembling, thus assuring ease in the process and accuracy of result.

The principle of the three-point suspension is carried out in Jackson models in a most effective way, by means of arms extending out in the plane of the flywheel, to the frame, and the front end of the power plant rests on a cross member. In this way, as the designer claims, the frame can twist around the power plant, in response to road inequalities, and the slight allowance for relative movement prevents the transfer of torsional moments to the power plant. Then, the shape of the crankcase, which is practically circular, is a good guarantee of stability in its relation as a beam on the supports, so that bearings are held in strict alignment.

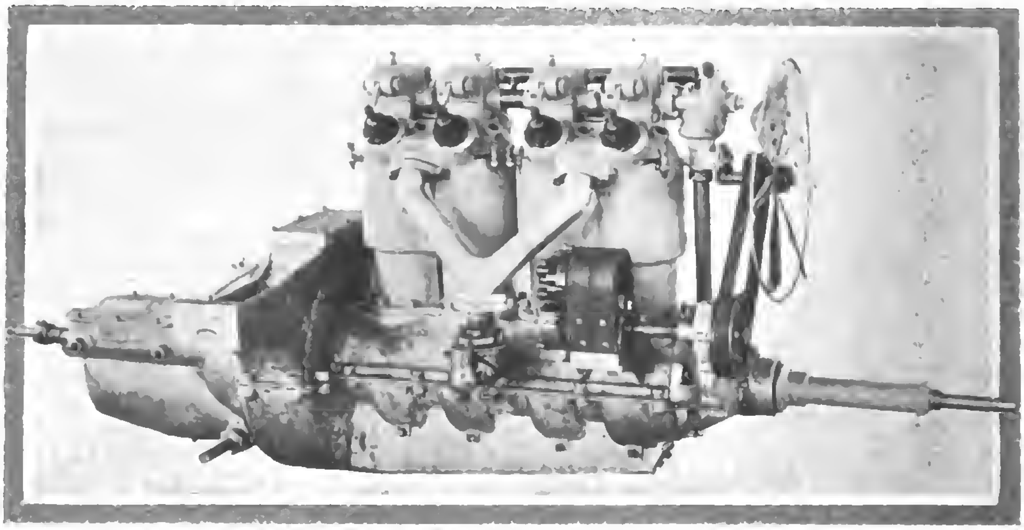

Fig. 4—Model 40 motor looking at intake side, showing carbureter, magneto, fan and cranking extension

Lubrication Is Positive and Novel—The lower half of the crankcase is separable, including the well for the flywheel, and an oil chamber extends all the way along, slanting towards the flywheel. Oil is placed in the flywheel chamber and is whisked up by the same, scraped off into a channel, and flows away to the respective bearings. All excesses of oil that land in the respective crank chambers, formed by cross walls in the crankcase, are picked up and landed into channels and flow on, increasing the tide of lubrication, which falls in profuse and continuous streams over the several bearings. From the bearing furthest from the flywheel a return channel is provided by virtue of which all the oil returns to the flywheel well, thus completing the cycle. This process of lubricating is continuous, and all that remains is to replenish the slight loss which is accounted for by the oil used to lubricate the pistons.

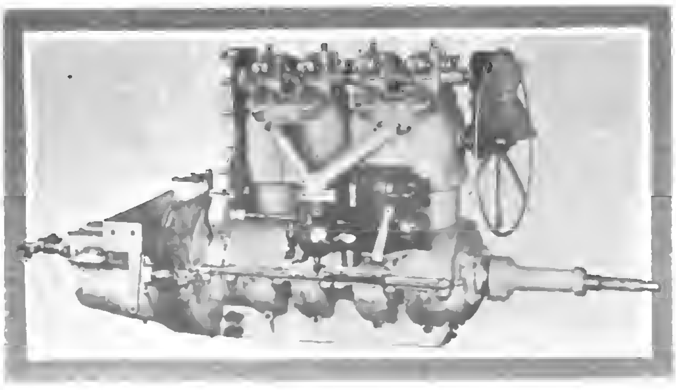

Fig. 5—Model 30 motor from intake side, showing housing for the silent chain drive for the camshaft

Dual Ignition Includes Magneto—Besides a coil and battery for use in starting and in an emergency, all models are provided with a Splitdorf magneto, located in front of the carbureter on the right side of the motor in each case. The magneto is flexibly installed, and the system of linkages and levers by which the spark is advanced and retarded is reduced to praiseworthy detail, free from lost motion and undue complication.

Fuel System Includes Scheb er Carbureter—The carbureter is placed on the right side of the power plant, low enough down with respect to the cylinders to assure that liquid fuel will not creep up and into the combustion chambers of the cylinders, hence carbon formations are aborted. The intake is of aluminum, with a branch to each individual cylinder in the 50 and to each pair of cylinders in the remaining models. The intake is absolutely tight, of a sectional area to deliver the exact requirement of mixture, remembering that it can be too large as well as too small. The Schebler carbureter, which, as a type, will not require explanation at this time, is selected for each model in point of size conforming to the best results, having experimented sufficiently to establish the governing facts. All piping from the gasoline tank, in each model, is made with a view to permanence, but provision is made for quick work if, perchance, foreign substances should collect in any quantity.

Cooling Is Aided by an Efficient Fan—The fan is placed just behind the radiator, between it and the front cylinder of the motor. It is of the latest die-formed type, with six blades of liberal area, set at an angle which is found to deliver the most air, and runs on ball bearings, fastened through a spindle of good diameter to a bracket of an adjustable type, extending out from the bevel gear housing of the camshaft. A wide flat belt drives the fan and takes its movement from a flanged pulley on the end of a spindle which has two bearings in an extension of the front end of the crankcase, and the gear which drives the spindle is enclosed meshing with a mate in its train, with a pinion on the crankshaft. The radiator, of liberal front area and sufficient depth, considering the excellence of the fan used and the hemispherical contour of the combustion chambers of the cylinders, maintains the temperature in all cylinders on an even level, and steaming is prevented, although the complication of a water pump is eliminated and the system works thermo-syphon.

Transmission and Other Notable Features—Models 50 and

40 deliver power to multiple disc clutches, as shown in Fig. 6, with large discs, submerged in lubricant, and actuated by a spring with positive release upon manipulating a foot pedal. The spring does not have to be of great strength, because its thrust is applied to a toggle system, which multiplies the thrust and gradually but positively applies an adequate pressure to the discs, pressing them into close contact, and when the foot pedal is pressed the discs are separated by springs placed for the purpose, one of which shows at B. The toggle system is adjusted by backing off the stud C and winding up the shell-spider D, all as indicated in Fig. 6. In this way lost motion due to wear of discs is taken up and the clutch, in each case, may be maintained in good working order at all times with a minimum of effort. Model 30 has a cone clutch, with a metal face, and runs in oil also.

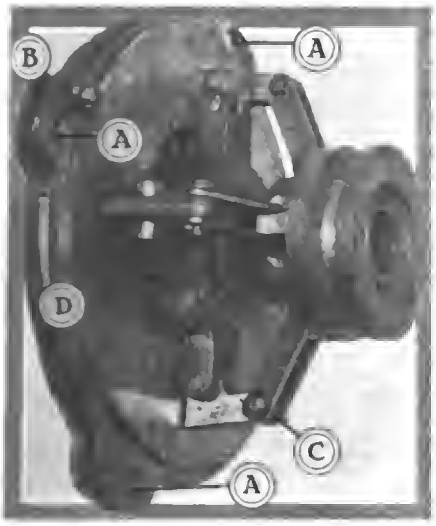

Fig. 6—Multiple disc clutch used on Models 40 and 50, showing toggle motion, discs and separating springs

The transmissions are of the three-speed selective type (and reverse) in each model, prime and lay shafts rotate on ball bearings, and the shifting selectors are of simple but positive design affording absolute certainty of action. The gears and shafts are of special steel, heat treated to bring out the desired hardness without loss of kinetic qualities. The teeth of the gears are wide, cut on Fellows' shapers to assure accuracy and mathematical precision of shape, and the ends of the teeth are chamfered on a special automatic machine to enable them to engage without shock or clash, while the aim is also to avoid cutting away an excess of the faces of the teeth in the chamfering process, which would reduce ability.

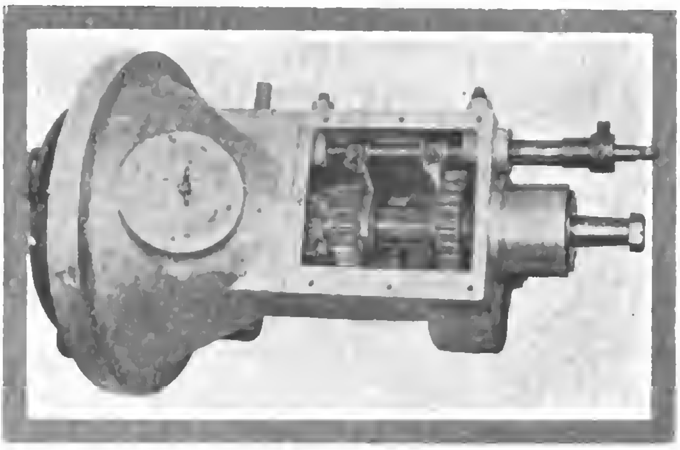

Fig. 7—Transmission and clutch case of Model 40, with cover off, disclosing transmission gears

Price Includes a Fine Array of **Equipment**—Besides a Splitdorf magneto on each model, there are the following considerations: Model 50, at $2,200, includes a wind shield and Prest-O-Lite tank, lamp equipment, tools, etc. The body is a standard touring design, of an advanced order in appearance and utility, seating five. At an extra cost of $50 two additional seats are provided, making it a seven-passenger car. This model is also delivered at $2,200 with a four-passenger tourabout body, which is regarded as one of the fine creations of the year.

Model 40, at $1,700, includes the usual equipment and a five-passenger body.

Model 30, at $1,250, will be furnished with a detachable tonneau, making it a five-passenger touring car, or it will be provided with a rumble seat, as a roadster, at the same price. The usual equipment is included at the price named.

The Jackson Automobile Company, at Jackson, Mich., with new additions to buildings and machinery, have 5,000 cars in the aggregate under way, and expects to deliver, as usual, on time. A large part of the increase over the last year's product is already placed, and a visit to the plant of the company disclosed a hive of industry, with system everywhere, all leading up to the great main issue, *i.e.*, the rapid completion, on a basis of accuracy, of more cars than were ever before contemplated.

PACKARD FACTORY SPREADS IN ALL DIRECTIONS

LOOKING over the plant of the Packard Motor Car Company, at Detroit, Mich., even at the expense of much time, discloses so many projects in process that it is with the greatest difficulty that a single story can be concentrated upon. The idea that crops out with the greatest prominence is, after all, one to be pictured better than told, and it represents the extent to which the company is putting up buildings, in order that this vast and growing business will be properly housed, taking into account the Packard ideas of permanence, convenience and to maintain the reputation of Packard cars.

Architecturally the buildings at the plant, when they were originally planned, took cognizance of the future, and foundations were laid with sufficient stability to allow of adding to the height in each case. Fig. 1 of the administration building shows how well the architects understood the situation, for, while adding 50 per cent. to the actual floor space, the project is carried on without the slightest inconvenience to the company. The original administration building was two stories high, and the floors are so weather-tight that they serve as a flat roof while the addition of a story is being made. All building work is done from the outside, and while the builders are pushing the work at top speed, even so, within the administration building, nothing of the usual builders' hubbub disturbs the serenity of the counting house, engineering office, laboratory, or headquarters offices.

Power Makes the Wheels Revolve—The power which emanates from the administration building would avail very little in the directions of actual results did it not include instructions to provide a sufficient addition to the power plant, so that the contemplated increase in machinery will include the power to run it. Fig. 2 is of the original power house and addition being made to it. When the building work is well along, power-plant equipment will be ready to install and in this way power to run the new machinery will be at hand at the proper time. As an incident it will be worth while to observe that the power plant is centrally situated, but somewhat isolated, so that the electrical transmission is made with a minimized loss, and in case of fire in any one of the buildings the power plant will not be in danger, and the fire hazard is reduced.

Scarcity of Material Demands Attention—The wise maker of automobiles will look to the source of material and in so far as it is possible to do so keep all such matters under direct control. The Packard is one of the American concerns which builds the entire automobile rather than to rely upon parts makers, and one of the more important questions lies in having a foundry at hand from which to procure good castings of every description. Fig. 3 depicts the new foundry in course of erection, and when this structure is completed, which will be at a very early date, the company will be in a far better position to do all of its own work of this character and on the extended basis required, as indicated by demand.

If it is important to have a foundry to draw upon, the same incentive holds with the woodworking plant, especially in view of body work. The Packard makes all its own bodies, and while they are of the class known as aluminum, the fact remains that the framing is of wood and demands treatment under conditions involving an extensive line of special woodworking machinery. Then, there are wheels to make, and such other parts as mahogany dash and other trim parts. Fig. 4 shows an extension of the woodworking plant, and since Packard bodies are of the most substantial character, in view of the large output of the company it is not to be wondered at if the woodworking plant is a very noticeable proportion of the whole establishment, ranking high in relative value.

Future Is Reflected as in a Mirror—The question is frequently asked: What is the future to be? Will commercial vehicles displace horses entirely? The Packard idea seems to be in favor of a horseless future, and Fig. 5 represents the new building, now being erected by the company, in which trucks will be built. In this is all the evidence necessary, showing that this company has faith in the future, and that commercial vehicles will be of the automobile genus, and that the remaining horses must go. Some two years past, when the Society of Automobile Engineers were entertained at the Packard plant, the truck work then attracted considerable attention, and the character of truck work being done was such that its future could not be accommodated in the plant as it then existed, filled as it was, at nearly every point, with pleasure car work. That the company had in mind a comprehensive scheme will now be seen, and it is a fair inference that there is now sufficient demand for trucks and other commercials of the character built by the company to warrant the expense of a large new addition.

An Industrial City Expanding—Gradually the plant expands; never a week goes by without witnessing the laying of a new foundation, and this has been the condition for several years. Despite this continual advance there is a picturesque similarity between all the buildings, and each one fronts on a wide brick-paved street. The impression is that of a large industrial city, with clean, well-paved streets and accommodation for traffic on a large scale. Fig. 6 portrays the situation at it exists throughout the entire plant, and with a view to adequate fire protection hydrants are placed at points of vantage, one of which is in the foreground. The sidewalks are wide, and here and there a bridge spans the streets, affording short cuts between departments, thus economizing in time required in the handling of materials, and in intercommunication.

Some of the Problems Are Engrossing—In observing the output of a plant account must be taken of the extent to which it is devoted to the manufacture of all the units that go into cars. In closely examining the Packard plant, for illustration, it is at once seen that much room is required in the manufacture of bodies. Of the whole force of men, footing up to the enormous number of more than five regiments of 1,000 each, not counting a full quarter of a regiment of officials and staff men, but relatively few of them are to be found in the body plant, despite the large amount of room required. In other parts of the plant there is a man for every square yard of space, and the obvious conclusion is that if a company builds every part of every car made (neglecting tires, ignition equipment, etc.), the amount of room needed, per car put out, will be far more than the average observer is likely to suppose.

True, the output in cars will be large or small depending upon the quality, and when the whole matter is simmered down to the last shred of sound reasoning, the output of a shop must be measured in dollars per square foot of floor space. In an estimate of this sort it is necessary to allow for the efficiency of the equipment used in the manufacture of the parts, and the extent of congestion of the space. It is a moral certainty that a very congested, poorly lighted building will result in inferior work and the real value of the product may then be far below the selling prices asked. These and many other reasons are at the bottom of the Packard plans, and it seems to be the idea there to provide commodious, sanitary, well-lighted buildings, and to do all the work, in order that the cars made will be in value, in the fullest accord, with the price asked.

The factory now comprises 21 acres of floor space in operation, with four acres under construction, as shown in the illustrations. Since there are now about 1,000 men on the night force, it may be that the addition of four acres of floor space will, to some extent, reduce the necessity for night work, the addition being in about the same ratio as the night force bears to the total force. This will, of course, bring good results, it being the case that night work is costly, and, on the whole, the best indication possible to show that the Packard plant must expand; hence the reason for the great activity as here portrayed.

THE AUTOMOBILE

Vol. XXI Thursday, October 14, 1909 No. 16

THE CLASS JOURNAL COMPANY

H. M. SWETLAND, President

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

AN IDEA IN GARAGE CONSTRUCTION

In the course of an excellent editorial article on the subject of "The Garage from the Practical and Hygienic Aspects," *The Motor Trader* (English) brings out an excellent point that pertains to the modern garage, public rather than private, but, nevertheless, of wide interest. This is to the general effect that the ordinary garage is very much lacking in the all-important matter of ventilation. It is a fact, usually lost sight of, that the exhaust vapors of an automobile engine consist to a large extent of carbon monoxide, which is a poisonous gas. In ordinary running in the air this matters little, for the gas is diffused through an enormous quantity, relatively, of air, so that its influence is very small and is not felt even in close proximity to the offending vehicle.

Within the close confines of the garage, whether the doors be closed or not, an engine exhausting for a period of several minutes vitiates no small amount of air, rendering it, first, unfit to breathe, and, later on, through the engine continuing to run indoors, actually poisonous. Perhaps this accounts for the mental sluggishness of the ordinary public garage attendant or employee. At any rate, in the construction of future garages, and the improvement of existing structures devoted to this use, the thought is well worth some consideration. The article said in part:

Then there is the question of the health of the inmates or employees to be regarded. Viewed from this standpoint, it would be hardly too much to affirm that, did the sanitary officers in many districts, particularly in the large towns, exercise even a part of their authority, they could insist on the remodelling or compulsory closing of very many motor garages and workshops. The danger here is not so much arising from a deficient cubic space per inmate, but the worse one of his breathing an atmosphere grossly injurious by the presence of a varying quantity of carbon monoxide. The condition of the average garage is decidedly dangerous in this respect. The fact that part of the employees' daily task lies in testing motors increases the extent of the responsibility of the owner by the same ratio as the danger is increased or reduced by such factors as the capacity of the premises for the work in hand, their state hygienically regarded, and the varying amount of the poison that is being discharged from the motors. Traders contemplating an adaptation of existing premises should consult their local authority and first satisfy themselves of the possibility of their being enabled to carry out what may be required, and should also not overlook the trend of modern workshop planning so as to insure the most healthful conditions to the workers.

In the smaller private garage structure this idea is worthy of even more consideration, for the reduced size of the building increases the danger from this cause. As a consequence, this matter of ventilation should be given increased thought by the owner about to build himself a garage or motor house.

YESTERDAY AND TO-DAY IN RACING

Public sentiment changes quickly. It seems but yesterday that the talk of a competition on the public roads called forth the threat of injunctions and other forms of interference. The authorities were fearful of permitting what was designated as "usurpation of the highways by speed-crazed beings who belonged behind the bars." Gradually it became evident that the general public regarded an automobile contest as the greatest spectacle of modern times, and, furthermore, wanted such events instead of having them suppressed.

When one reads of a 200-mile race in Fairmount Park, Philadelphia, with a thousand and more city police guarding the course in the presence of a Mayor who had no hesitancy in presenting the prize to the winning driver, the fact is brought home somewhat startlingly of the present liberal attitude of the public officials, brought about undoubtedly by the knowledge that the people themselves are thoroughly in favor of a motor holiday.

Over such a tortuous course as the one in Fairmount Park cars are tested in every particular, and, while the personal equation, in the form of the driver, enters into the contest and makes it one of man and machine, the fact remains that any car which can survive such a gruelling examination creditably is worthy of the patronage of the discriminating buying public. There are still a few discrepancies in the exact definition of a "stock" chassis, but the rules governing are much nearer perfection than ever before, with indications that necessary revisions will make the 1910 competitions open only to cars the mates of which will be found in the salesrooms of every reputable manufacturer believing in one or another form of competition as a means of publicly demonstrating the worth of his product.

As to the exact future of racing there seems to be much difference of opinion, though indications are that the season of 1910 will be marked by a plethora of contests throughout the country, perhaps attaining a climax to be followed by a lessening of public interest. The agitation to revive the Grand Prix in France would foster the belief that the foreign manufacturers had found an entire absence of racing somewhat detrimental as a whole, though the class abroad most interested in competition has turned to the flying brigade.

CHICAGO SHOW HAS TWICE TOO MANY APPLICANTS

TWICE too many applications for the space available at the Chicago show, February 5 to 12, next, was the problem that confronted the management at the session held October 6 at the N. A. A. M. headquarters, No. 7 East Forty-second street, New York City. There were just 104 applications for space in the automobile section. Heretofore automobile exhibits have been confined to the main floors of the Coliseum, Annex, and First Regiment Armory, while a few cars have been placed in the Coliseum basement. This year, after exhausting the entire basement, there were still eight automobile manufacturers for whom it was impossible to provide any space at all, but who will, of course, be given the first opportunity to take advantage of any withdrawals. Since the allotment six other automobile manufacturing concerns have applied for space, so that there are now fourteen on the waiting list.

The entire gallery of the Coliseum, and the principal part of the second floor of the Coliseum Annex have been allotted, as heretofore, to the Motor & Accessory Manufacturers, who will make their own allotment. At this time the number of applications from members of that association is greater than in any previous year. All remaining space on the second floor of the Coliseum Annex is reserved for the Motorcycle Section. There are twenty spaces and applications in hand for over forty. Unattached makers of accessories have been given the gallery of the First Regiment Armory. It was necessary to allot them one space apiece, and even then there is not enough space in this section to go around. This is an unfortunate situation, for the luckless ones will have to buy space from those given space.

A list of the manufacturers of automobiles who have been allotted space is appended:

American Locomotive Company	Providence, R. I.
American Motor Car Company	Indianapolis
Anderson Carriage Company	Detroit
Apperson Bros. Automobile Company	Kokomo, Ind.
Atlas Motor Car Company	Springfield, Mass.
Auburn Automobile Company	Auburn, Ind.
Austin Automobile Company	Grand Rapids, Mich.
Baker Motor Vehicle Company	Cleveland
Bartholomew Company	Peoria, Ill.
Berliet Import Company	Chicago
Black Mfg. Co	Chicago
Brush Runabout Company	Detroit
Buckeye Mfg. Co	Anderson, Ind.
Buick Motor Company	Flint, Mich.
Cadillac Motor Car Company	Detroit
Cameron Car Company	Beverly, Mass.
Cartercar Company	Pontiac, Mich.
Chadwick Engineering Works	Pottstown, Pa.
Chalmers-Detroit Motor Company	Detroit
Columbia Motor Car Company	Hartford, Conn.
Columbus Buggy Company	Cleveland
Corbin Motor Vehicle Corp	New Britain, Conn.
Dayton Motor Car Company	Dayton, O.
Dorris Motor Car Company	St. Louis
Elkhart Motor Car Company	Elkhart, Ind.
Elmore Mfg. Co	Clyde, O.
Everitt-Metzger-Flanders Company	Detroit
F. A. L. Motor Company	Chicago
Fiat Automobile Company	New York
Franklin Mfg. Co., H. H	Syracuse, N. Y.
Fuller Buggy Company	Jackson, Mich.
Gaeth Automobile Company	Cleveland
Grabowsky Power Wagon Company	Detroit
Great Western Automobile Company	Peru, Ind.
Haynes Automobile Company	Kokomo, Ind.
Holsman Automobile Company	Chicago
Hudson Motor Car Company	Detroit
Hupp Motor Car Company	Detroit
International Harvester Company	Chicago
Interstate Automobile Company	Muncie, Ind.
Jackson Automobile Company	Jackson, Mich.
Jeffery & Company, Thos. B	Kenosha, Wis.
Jewel Carriage Company	Cincinnati
Kimball & Company, C. P	Chicago
Kissel Motor Car Company	Hartford, Wis.
Knox Automobile Company	Springfield, Mass.
Lion Motor Car Company	Adrian, Mich.
Locomobile Co. of America	Bridgeport, Conn.
Lozier Motor Company	New York City
Matheson Motor Car Company	Wilkes-Barre, Pa.
Maxwell-Briscoe Company	Tarrytown, N. Y.
McIntyre Company, W. H	Auburn, Ind.
Metzger Motor Car Company	Detroit
Midland Motor Car Company	Moline, Ill.
Mitchell Motor Car Company	Racine, Wis.
Moline Automobile Company	East Moline, Ill.
Moon Motor Car Company	St. Louis
National Motor Vehicle Company	Indianapolis
Nora Motor Car Company	Newark, N. Y.
Nordyke & Marmon Company	Indianapolis
Oakland Motor Car Company	Pontiac, Mich.
Olds Motor Works	Lansing, Mich.
Packard Motor Car Company	Detroit
Palais de l'Automobile	New York
Peerless Motor Car Company	Cleveland
Pennsylvania Auto-Motor Company	Bryn Mawr, Pa.
Pierce-Arrow Motor Car Company	Buffalo
Pope Mfg. Co	Hartford, Conn.
Premier Motor Mfg. Co	Indianapolis
Rapid Motor Vehicle Company	Pontiac, Mich.
Rauch & Lang Carriage Company	Columbus, O.
Regal Motor Car Company	Detroit
Renault Freres Selling Branch, Inc	New York
Reo Motor Car Company	Detroit
Ricketts Auto Works	South Bend, Ind.
Rider-Lewis Motor Car Company	Muncie, Ind.
Royal Tourist Car Company	Cleveland
Schacht Mfg. Co	Cincinnati
Selden Motor Vehicle Company	Rochester, N. Y.
Speedwell Motor Car Company	Dayton, O.
Simplex Motor Car Company	Mishawaka, Ind.
St. Louis Car Company	St. Louis
Staver Carriage Company	Chicago
Stearns Company, The F. B	Cleveland
Stevens-Duryea Company	Chicopee Falls, Mass.
Streator Motor Car Company	Streator, Ill.
Studebaker Automobile Company	Cleveland
Studebaker Automobile Company	Cleveland
The White Company	Cleveland
Thomas Motor Company, E. R	Buffalo
Toledo Motor Company (Overland)	Toledo, O.
Waverly Company	Indianapolis
Wayne Works	Richmond, Ind.
Winton Motor Carriage Company	Cleveland
Woods Motor Vehicle Company	Chicago
Woods Motor Vehicle Company	Chicago
York Motor Car Company	York, Pa.
Zimmerman Mfg. Co	Auburn, Ind.

HOW PALACE SHOW EXHIBITORS WILL BE PLACED

AT the recent drawing for space in the Tenth International Automobile Show, which will open New Year's Eve in Grand Central Palace, New York, 37 members of the American Motor Car Manufacturers' Association secured preferred space on the main floor, while more than 40 makers not members of the A. M. C. M. A. and 125 accessory concerns not included in membership of the Motor and Accessory Manufacturers, Inc., were allotted space on the first and second balconies. All records for space in automobile shows were broken, as 305 motor car makers and accessory manufacturers were allotted space. At no time in the history of the Palace Show has the show committee met with as much difficulty in trying to satisfy demands for space as this year. An unusual demand was made for space by members of the A. M. C. M. A. and other motor car makers, while outside accessory firms fairly deluged Chairman R. E. Olds and his associates with applications. The Ford Motor Company, of Detroit, secured the first draw, and selected the same space in which Ford cars have been exhibited for the past two years. Other concerns securing large spaces include Reo Motor Car Co., Brush Runabout Co., Premier Motor Manufacturing Co., Mitchell Motor Car Co., Dayton Motor Car Co., Maxwell-Briscoe Motor Co., Jackson Automobile Company and Mora Motor Car Company.

Other members of the A. M. C. M. A. who drew preferred space include Oakland, Marmon, Regal, Pullman, Moline, Lambert, Atlas, Hupmobile, National, McIntyre, American Simplex, Austin, Pennsylvania, Moon, Cartercar, American, Holsman, Pierce, Chadwick, Glide, Standard, Ohio, Gaeth, Speedwell and Midland. Of the commercial motor car makers belonging to the A. M. C. M. A. who secured preferred space on the first balcony are Rapid, Mack and Grabowsky.

As was the case last year, members of the Importers' Automobile Salon have secured a block of preferred space on the main floor, which has been secured by Fiat, C. G. V., Panhard, Renault, Lancia, Isotta, De Dietrich, Clement, Delahaye, Delaunay-Belleville, DeDion, Hotchkiss, Zust and S. P. O.

Pleasure vehicle makers who were allotted space on the first balcony include Croxton-Keeton, Kissel Kar, Inter-State, Kline Kar, Benz, Black, Cameron, Coates-Goshen, Columbus, Crawford, Empire, Houpt, McCue, Everett, Sultan and Allen-Kingston. Commercial vehicle makers on the first balcony not members of the A. M. C. M. A. are the Gramm-Logan, Hart Kraft, Lansden, Martin, Saurer, DeDion and Randolph.

On the second balcony will be found not only accessory makers as in the past, but about 18 makers of cars.

Contracts for the spaces alotted are being mailed.

LICENSED BODY AGAIN INCLUDES OLDS AND BUICK

WHILE an announcement outlining A. L. A. M. plans is anticipated within the next few days, it is now known that the General Motors Company group will be licensed makers. Whatever differences existed between the Licensed body and the Buick company have been satisfactorily adjusted, and the Olds Motor Works has been reinstated to active membership, which means that these concerns will be seen in the Garden show for the first time in two years. W. C. Durant, the vital factor in the General Motors segregation, is authority for the information.

Developments in relation to the Ford Motor Company have been somewhat sluggish, which means that the situation is the same as it was before. Henry Ford preferred to carry the burden of the Selden suit himself without any outside assistance, and apparently he intends to continue his attitude.

In the first story of the startling developments, printed in THE AUTOMOBILE of last week, seven A. M. C. M. A. concerns were given as assured new members of the A. L. A. M. These were Maxwell, Reo, Premier, Mitchell, Dayton, Jackson, and Regal. The last named being one of the later entrants into the industry, it is understood that its Licensed connection will be on slightly different lines to that of the others. In fact, the impression prevails that conditions governing not a few of the probable applicants may result in two kinds of membership. The continued healthy state of the industry is a condition generally desired, and it is believed that the present direction of A. L. A. M. affairs will not be subjected to any radical interference.

In obtaining the order of the court's decree, the Licensed Association is meeting with a slight delay because of the change in name of the Electric Vehicle Company to the Columbia Motor Car Company. While this has no effect whatever upon the decision itself, the delay interferes with plans mapped out.

The A. M. C. M. A. members who have joined the A. L. A. M. will retain their membership in the former body, and participate as usual in the Grand Central Palace show.

"Membership in our association has nothing to do with the Selden patent," said Alfred Reeves, the A. M. C. M. A. general manager, "and twenty-five of our members might in the end become members of the A. L. A. M. also."

WHAT THE N. A. A. M. EXECUTIVE COMMITTEE DECIDED UPON

TO a special committee consisting of L. H. Kittredge, W. R. Innis and Charles Clifton has been referred the question of the advisability of amending the standard warranty of the N. A. A. M. This action was taken at the regular October meeting of the executive committee, held at the New York headquarters, 7 East Forty-second street, October 6.

Frank Briscoe, representing the Brush Runabout Company; W. C. Johnson, representing the Waverley Company; W. H. Van Devoort, representing the Moline Automobile Company; R. H. Salmons, representing the Selden Motor Vehicle Company, and W. S. Austin, representing the Austin Automobile Company, were elected to membership.

The membership of the Electric Vehicle Company was transferred to the Columbia Motor Car Company, represented by H. W. Nuckols, and the membership of the Royal Motor Car Company to the Royal Tourist Motor Company, represented by George J. Dunham.

The executive committee decided to actively support the promotion of a convention to be held in Washington, either in December or January, designed to promote the interests of the National registration bill now before Congress. This matter is in the hands of the legislative committee and of Charles Thaddeus Terry, the association's counsel. It will be pushed vigorously and the results will doubtless show, that it was worth while.

IMPORTANT DECISIONS OF THE A. A. A. CONTEST BOARD

PROTESTS of a varied sort were passed upon by the Contest Board of the A. A. A. at a session held in New York City, October 5 and 6, the entire board being present.

In connection with the 1909 A. A. A. reliability tour, the protests of H. O. Smith and W. H. VanDevoort, entrants of the Premier and Moline cars, respectively, against the findings of the technical committee on the two Pierce touring cars and No. 108 Pierce runabout, were withdrawn.

The action of S. B. Stevens in calling off the 300-mile race of August 21 on the Indianapolis motor speedway was sustained, and in addition to denying the protest of the Jackson Automobile Company, that concern was disciplined by suspension from entering any contest until January 1, 1910, for advertising that it had won the race in question.

The Premier Motor Manufacturing Company's protest against the Quaker City Motor Club was sustained. The protest was on penalties imposed for time in checking at controls after the blockade at Giant's Despair, Wilkes-Barre, Pa., during the Quaker club's Spring endurance run. It was found that the subject hinged on part of the instructions given the contestants by a representative of the club at the instruction meeting, wherein it was stated in substance that, owing to road conditions, if a blockade occurred to a contesting car by reason of a disabled car, the committee would take care of it.

Relative to the appeal of the Dayton Motor Car Company in the hill climb of the Automobile Club of Cincinnati, two protests were entered against awarding the first prize to the Stoddard-Dayton car on the ground that the car was not "stock" in the meaning of the definition in the rules, and the referee decided in favor of the appellants.

On the report of the referee of the Brighton Beach races, August 27, and of a member of the contest board present, the entrant and driver of S. P. O. Car No. 1 were each suspended to January 1, 1910, and the driver fined $100 and suspended.

What the Clubs Are Doing These Days

STATE COMMISSIONER TO LEAD TIME RUN

HARTFORD, CONN., Oct. 11—State Highway Commissioner MacDonald will set the pace for the sociability and secret-time run of the Automobile Club of Hartford, to be held October 22. The purpose of the event is to celebrate the opening of the new seven-mile Berlin turnpike, which will also furnish the course for the run. On the return trip from Berlin to Hartford the commissioner will drive his car at what he believes a proper speed, both for safety and for the preservation of the road. His time will be taken and placed in a sealed envelope. The contestants will be started at one-minute intervals, and each will attempt to approximate the commissioner's time. Several prizes have been offered. The winners will be announced at a banquet at the Allyn House.

MILWAUKEE CONSIDERING A CLUBHOUSE

MILWAUKEE, WIS., Oct. 11—At the annual meeting of the Milwaukee Automobile Club the following directors were elected: M. C. Moore and C. W. Norris, to serve two years; C. S. Drake, Christian Scholtka, M. W. Pipkorn, J. E. Farber and J. F. Schreiber, to serve three years. Officers will be elected at a meeting to be held October 15. President C. S. Drake's report showed that the membership now is 355 and the assets are $9,000. The cash balance on October 1 was $2,634.29, and in addition the club owns three acres of choice land purchased for a clubhouse site. Mr. Drake urged immediate action toward the erection of the building.

COLUMBUS CLUB BUSY ERECTING ROAD SIGNS

COLUMBUS, O., Oct. 11—A number of the members of the Columbus Automobile Club spent several days in erecting road signs on the highways to the west of Columbus. The signs are much larger than those used earlier in the year, most of which have been destroyed by vandals. The club expects to cover all the highways with both danger signs and road directions.

WESTERN NEW YORK CLUBS PLAN SHOWS

BINGHAMTON, N. Y., Oct. 11—The automobile clubs of Buffalo, Binghamton, Rochester and Syracuse are planning to arrange their shows next spring in a circuit, with dates following each other in such a way that one exhibit can make the entire circuit. Binghamton's date has been fixed for February 21 to 26. Buffalo is deciding between the fourth week of February and the second week in March. Syracuse has under consideration some week in March which will not conflict with the others, and Rochester agrees that if its show is a club affair it will carry out the same plan.

DELAWARE ASSOCIATION MEETING AND ELECTION

WILMINGTON, DEL., Oct. 11—The Delaware Automobile Association held its annual meeting here last week, and elected the following officers: President, J. Danforth Bush; vice-president, A. B. Hazzard; secretary, Charles G. Guyer; treasurer, William Stanier; executive committee, Joseph Bancroft, John B. Bird, Frank J. Cheney, Louis A. Drexler and William C. Corey. All are residents of Wilmington except Mr. Corey, who lives at Bethany Beach. The year book for 1910, which is being prepared by the association, will contain maps showing all the roads of the State and their condition.

WORKING FOR ROADS IN NORTHERN INDIANA

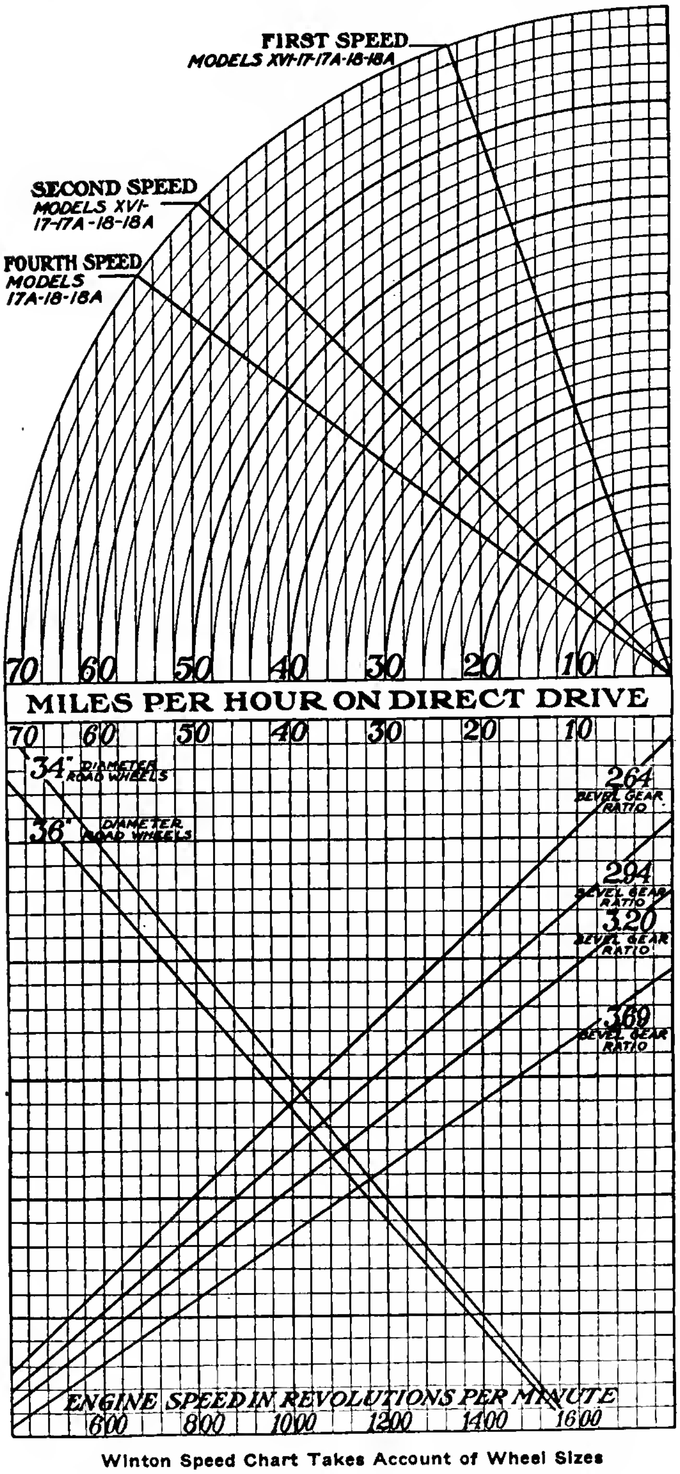
SOUTH BEND, IND., Oct. 11—At the recent meeting of the automobile club of this city in the Oliver, a movement was launched for the general improvement of the roads of the county. A committee was appointed to confer with the officials of Laporte County, where several hundred miles of macadam roads have been built, to find their cost and maintenance expense. M. L. Brummit, a member of the county council, was present and submitted a report on the proceedings of the good roads convention at Cleveland, to which he was a delegate.

North Pole Controversy Gives A. M. C. M. A. Manager Reeves a Bright Idea

First honors in the decorated automobile parade in honor of the Hudson-Fulton celebration, at Yonkers, N. Y., were awarded to Masters Clifford and Robert Reeves, the children of Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, who represented the rival Arctic explorers, Dr. Cook and Commander Peary. The float on the Maxwell car represented an Arctic scene, with the North Pole in full view, surmounted by an American flag, with Teddy bears climbing to the top. There were polar bear decorations, and icicles and snow galore. Mr. and Mrs. Reeves in black furs represented esquimaux, while the two youngsters in full snow-white Arctic costumes represented the North Pole explorers.

USEFUL AND SIMPLE SPEED CHART

"Very handy" describes the speed chart just issued by the Winton Motor Carriage Company, Cleveland. It consists of two parts: the lower and the upper. The lower is rectangular in shape and has six diagonals, four extending upward to the right, which are for the four Winton gear ratios. The other two diagonals extend upward to the left and are for 34-inch and 36-



Winton Speed Chart Takes Account of Wheel Sizes

inch wheels. The upper portion is devoted to the three indirect speeds, three diagonals intersecting a series of circles denoting the speed in miles per hour. To use, if the engine speed is known, start on the bottom horizontal at that speed, and proceed upward to the diagonal indicating the gear ratio. Then go across horizontally until the diagonal for the wheel size is reached. This last intersection is the start of the second vertical movement, which is continued until the miles per hour are obtained. For the third, or direct, drive, this is read direct at the top line, but for the other indirect speeds the process varies. On first and second, follow around the arc to the diagonal, thence straight downward. On high or fourth speed, however, follow up on a straight line to the diagonal, thence back around the arc to the speed. Knowing any three of the four variables it is possible to find the other one by working backward.

Thus, if it is desired at any time to tell the speed of the engine, having a speedometer on the car, and knowing wheel size and gear reduction, proceed as follows: Start from the speed, then proceed upward to the speed diagonal in the reverse of the manner just described. Then a vertical will be obtained, which follow down to intersect the wheel diagonal. Then go across to cut the gear diagonal, and a perpendicular to the base line will give the desired speed of rotation of the engine.

This is a very handy chart to have, and all Winton owners will doubtless hasten to get and use one. It is to be regretted that the several diagonals on the lower part were not made more numerous, to allow of the use of the table by all automobile owners. Thus, if all gear ratios in even figures from 2.5 to 4 and all wheel diameters from 32 to 42 had been given, it would have been universal. The latter diagram, too, would have allowed a number of interesting deductions, as, for instance, the man with 34-inch wheels could read not only the speed at a given engine speed, but could figure out how much faster he would be traveling with the same engine speed if he but had 36, 38 and other larger-sized wheels; that is, this very handy and quickly used diagram would have been more handy and could be used just as quickly.

CAR'S AGE DIDN'T CHANGE MATTERS

Baltimore, Oct. 10—In the first case ever tried in this city for a loss sustained upon an automobile insurance policy a verdict was rendered in favor of the plaintiff, William P. Cummings, of this city, against the British and Foreign Marine Insurance Company, Limited, of Liverpool. Mr. Cummings purchased a Pope-Hartford machine of the make of 1907, which he had insured for $1,500, paying a premium of $60. The machine was subsequently destroyed by fire, when it was discovered to have been a 1906 car. The insurance company raised this point, saying that the defendant company would not have insured a 1906 car for the same amount. The case was tried before Judge Elliott and a jury in the Court of Common Pleas. The court refused all the contentions of the company and the jury rendered a verdict for the full amount of the policy, with interest to date, less the present value of the car as shown by the testimony. The total amount awarded Mr. Cummings was $1,430.

AMATEUR WINNER OF MUNSEY HONORED

Philadelphia, Oct. 11—At the Quaker City Motor Club last Saturday night, Gawthrop and Wister, local Elmore agents, presented a handsomely designed solid silver punch bowl to Frank Hardart, Jr., in recognition of his sterling work in capturing premier honors in the recent Munsey run from Wash- turing premier honors in the recent Munsey run from Washington to Boston and return. It will be recalled that Hardart's car finished that strenuous journey without a solitary road or technical penalty recorded against it—a most meritorious performance for car and driver, especially in view of the fact that Hardart is an amateur. Mayor Reyburn made the speech of presentation.

Gainesville, Fla.—The Cook Automobile Company has found it necessary to have its garage nearly doubled in size. An addition 50 by 60 feet will be built, extending the quarters to a length of 120 feet. The automobile fever seems to have struck the town and already 40 cars are owned by its residents, many of them having been purchased within the last four months.

FALSE IMPRESSIONS TEMPT INEXPERIENCED

By FRED W. HAINES, General Manager Regal Motor Car Co.

When reading the publications devoted to the automobile industry a person cannot help but wonder at the large number of new companies entering, or attempting to enter, the field. The desire on the part of men with money to get into the automobile business seems to amount almost to a craze, and it is now the easiest thing in the world to organize an automobile company and secure capital.

If people investing money in automobile manufacture had any idea of the troubles which have to be gone through and overcome before their business can be at all successful, if they had any conception of the many dangers to their investments, I really believe that they would be more careful in risking their capital than they apparently are.

The word "automobile" and the idea of manufacturing automobiles seems to have a magic sound to the ears of most people at the present time, and the abnormal increase in manufacture can only end in one way for the vast majority of these companies; and that way is failure.

It is a well-acknowledged fact among manufacturers, and it is now well known to most purchasers, that the first year's production of automobiles by any concern is bound to be inferior in a great many ways, and the purchaser now hesitates to buy a new production, no matter how well it may be backed by both experience and capital. There have been some exceptions to this rule, but it is so seldom that it is never noticed.

A new concern starting in, therefore, must have practically unlimited capital, and at the same time men with practical experience to guide the new company through its first year of life. In too many cases a company is promoted and its only asset is some supposed drawings made by a draftsman who has been employed by one of the older companies. In ninety-nine cases out of a hundred these drawings are not only incorrect, but incomplete, and from these drawings to the actual production of cars the way is very long and exceedingly hard.

The prospect of sales is very alluring, and it seems to be the easiest thing in the world to dispose of any old thing that may be manufactured. An automobile sale, however, is about the most unreliable kind of a sale, as it is subject to cancellation at any time before the money has actually been paid and the car delivered.

Another great trouble with the automobile business is the fact that almost every manufacturer overbuys on all his material, with the idea that if he does not actually need the parts he can cancel any part of the order at any time. The parts manufacturer, realizing this condition and the liability of a cancellation, in order to protect himself oversells on his production, so that he will not be able to produce anywhere near the number of parts he has contracted for.

Therefore, on account of the absolute unreliability of the contract made by both the automobile manufacturer and the parts maker, the entire production of cars depends upon the ability of the automobile manufacturer to secure a sufficient number of parts from the parts maker and to keep his entire stock of parts well balanced. A great many of the failures in automobile companies is caused by the seeming impossibility to secure needed material, and for 1910 this condition is going to be noticed more than ever. The enormous estimated production of cars for 1910 is about four hundred per cent. in advance of the actual production for 1909. The parts makers in 1909 were pushed to their fullest capacity, and the liberal estimate of an increase of fifty per cent. for the coming season will certainly account for all the increase that the parts manufacturers will actually be able to produce. It is, therefore, easy to see that the great majority of new automobile companies will find it practically impossible to secure any number of parts, and will wind up the coming season in a bad way financially.

This craze to get into the automobile business, to my mind, is brought about entirely by the successful manufacturers. The tendency to greatly overestimate their production, and also their profits, when advertising, cannot be too strongly condemned, as it not only accounts for the desire of others to get into this apparently successful business, but it creates in the minds of the buying public an idea that practically fifty per cent. of the retail price of an automobile represents clear profit. This reason undoubtedly prevents a great many people from purchasing cars, as a man certainly would hesitate at paying an exorbitant price for any goods. It also creates a demand for cut prices from the retail dealer, as it is very hard for him to convince a prospective purchaser that he is working on a small margin of profit, and it is impossible for him to cut prices.

Every new company getting in the business, if it only builds a few cars, simply takes that much business away from the established concerns, and in the majority of cases the few cars that they do build fall down badly when sold, and in that way create an unfavorable impression of the automobile in general, not only with the purchaser of that particular car, but his friends also.

If the automobile manufacturers in their advertisements, and in all other ways, would stick exactly to the truth in regard to their production, and if they would be willing to show the public in general the immense amount of detail necessary to the production of a first-class machine, the high efficiency of the men required, and the absolute accuracy of all workmanship used, I think it would go a long way toward convincing the public in general that an automobile manufacturer's business is not entirely all profit, and is certainly not a bed of roses at any stage.

WHAT MUST BE PROVED TO PLACE GUILT

Hartford, Conn., Oct. 11—Mrs. Lucy R. Eldridge, wife of Commander Frank H. Eldridge, U. S. N., retired, has been bound over to the December term of the Superior Court on a charge of manslaughter, and is held under $3,000 bond, which has been furnished. Mrs. Eldridge, while coming through West Hartford, September 29, in her automobile, struck and killed a seven-year-old boy. A chauffeur in the employ of the Columbia Motor Car Company, who was with Mrs. Eldridge in the car, testified that she did everything in her power to avoid the accident, and that he himself could have done no better. The car was running at 12 or 15 miles an hour. Mrs. Eldridge stopped immediately and tried to help the boy.

The case was tried before Justice Alexander J. Keeney, and Grand Juror Carl C. Thompson prosecuted for the State. Arthur L. Shipman, counsel for the defense, claimed that it was necessary to show negligence, criminal intent, wantonness or culpability before manslaughter could be proved, and denied that the prosecutor had shown any of these elements in the evidence introduced, which was chiefly that of a six-year-old boy. Nevertheless, Justice Keeney bound over the defendant. The case has attracted much attention because of the prominence of the parties involved, and it is generally held to be a rank instance of autophobia.

DENVER ENACTS TRAFFIC ORDINANCE

Denver, Colo., Oct. 11—The Board of Aldermen of this city has enacted an ordinance establishing the right-of-way of vehicles at street intersections, which fills an important gap in the laws regulating traffic. This rule, which is section 1703 of Ordinance 124, reads as follows: "It shall be the duty of every person driving any vehicle, when approaching any intersecting street, alley or public way, to halt or slow up and allow any other vehicle approaching along the intersecting street on the right to have the right of way." Another section of this ordinance requires an overtaken vehicle to turn out to the right when signaled to do so by a vehicle approaching from behind.

The wording of the statute relative to slowing at crossings is somewhat ambiguous, since it is not made clear which vehicle would have the right of way, and which would have to wait, but as a whole, is expected to prove of much value.

Detroit American League Champions Trying Out New Rambler Model Fifty-Five

Baseball enthusiasts will be interested in this picture of the present opponents of the Pirates for the Championship, taken recently while in Boston. Aside from the famous Cobb, who will open a Southern agency for a Detroit car, Manager Jennings, seated right behind the driver in this picture, is also very much interested in automobiles. He was much pleased with the showing of the new Rambler in and about Boston, and expressed a wish at the time that he had more time to ride. It is reported that he will purchase a car upon the close of the present World's Championship series.

Shipping Autos by Express—When an automobile buyer wants his car bad enough to pay the difference between freight and express to get it a few days earlier, the company that made the car has good reason to pat itself on the back. The F. B. Stearns Company had such an experience recently, and the autos went by carloads all the way from Cleveland to Los Angeles. Coney C. Slaughter, the Stearns agent in the latter city, was responsible for the hurry-up order. After enduring the impatience of his clients as long as he could, he got the Stearns factory on the wire just as the cars were starting for the freight station. It cost $1,000 to transfer the shipment to express, but Los Angeles doesn't care about that.

Mrs. Cuneo's New Records—Driving the Rainier which finished second in the Long Island Derby, Mrs. Joan Newton Cuneo made new records for the mile and five miles on a half-mile track in the races at Danbury, Conn. She drove the mile in 1:19, beating the previous mark by 12 seconds, and covered the five-mile in 7:19, cutting the former record by nearly a minute. The car in the case was the regular 45-horsepower stock chassis which is entered in the coming Brighton 24-hour race. The Rainier Company claims a record for the number of second places won this year in races by this stock model, usually competing with cars of much greater power.

Electrics for Dairy Use—Rapid transit is the primary requirement in the dairies which supply large cities with milk, and here as elsewhere the horse has been found too slow. The Faitfield Dairy Company, Montclair, N. J., recently received from the Baker Motor Vehicle Company, of Cleveland, a one-ton electric truck to be used for hauling milk cans to the railroad. This machine has a 92-inch wheelbase and 34-inch wheels shod with 3 1-2-inch tires. Its power plant consists of a 42-cell 9 M. V. Exide battery and a 3 1-2-horsepower series-wound motor, capable of 300 per cent. overload. Its performance will be watched with interest.

Speed Limit for Locomobiles—The amended Indiana automobile law is entitled, according to the heavy type on the front page of the booklet, "An Act to Regulate the Speed, Operation and Registration of Locomobiles, Motor Cycles or Other Motor Vehicles Upon Public Highways." The Locomobile Company of America has called attention to this mistake, humorously suggesting that it may be due to the well known possibilities of the Locomobile in the way of speed. However, it hardly seems fair that the many law-abiding Locomobile drivers should have this formidable piece of legislation pointed so unmistakeably in their direction.

American Simplex Meeting—About 25 stockholders, representing two-thirds of the stock of the Simplex Motor Car Company, were present at the annual meeting at the factory in Mishawaka, Ind. The following officers were elected: T. C. Starrett, of Detroit, president; R. E. Kamm and E. J. Gulick, of Mishawaka, vice-president and secretary and general manager respectively, and D. A. Shaw, of Detroit, treasurer. The directors include Messrs. Shaw and Gulick, H. M. Hovey and George Grant, of Detroit, and J. T. Knorr, of La Mars, Ia. Much elation was felt over the car's good showing in the Munsey run.

Activity in Moline Plant—The demand for Moline cars since the Glidden tour has forced the Moline Automobile Company to build a large addition to its plant in East Moline, Ill. At present a large four-story building is being rushed to completion, which will give an additional floor space of 60,000 square feet. This will be used chiefly for chassis building and assembling. In the other departments of the factory there is also great activity, and each is working to the limit of its capacity to keep pace with orders which have already been received for the 1910 models.

Warner Gears Are Flourishing—In order to avoid attempting to move into a new factory at the height of the rush season, the Warner Mfg. Co. has concluded to remain in its present plant in Toledo, O., till spring, merely relieving congestion by renting additional space. This arrangement, however, is temporary only. T. W. Warner, president of the company, emphatically denies that it is connected with the Overland Automobile Company, but says that it is making steering and change-gears for 1910 Overland cars on contract.

Bergdoll to Make Cars—Louis J. Bergdoll, the Philadelphian driver of Benz cars, has organized a company to manufacture a $1,500 car in touring, runabout and taxicab models. The first year's output will be about 150 machines. This will be the first automobile factory in Philadelphia, although that city furnishes many parts and accessories to the trade and contains many big manufacturing plants, insuring an abundance of skilled labor.

Graphite from Niagara—A building 50 by 105 feet is to be added to the Niagara Falls, Ont., plant of the International Acheson Graphite Company, Niagara Falls, N. Y. The building will contain a new grinding plant in which to prepare the various grades of graphite, for lubricating and other purposes, and also a shipping room and stock room for package goods, such as the graphite greases, powders, etc., made by the company.

Cameron May Move to Virginia—It is reported that the Cameron Car Company, of Beverly, Mass., contemplates establishing another plant for the manufacture of commercial cars in Norfolk, Va., in addition to its present factory. Inquiries have been made as to whether local magnates would consider raising a $100,000 stock subscription on condition that the new factory employs 300 men.

Peru Gets Wheel Factory—Negotiations have been practically completed for the removal of the Salisbury Auto Wheel Company, at present of Jamestown, N. Y., to Peru, Ind. Peruvian capitalists have subscribed $60,000 of the stock of the company, which is capitalized at $200,000. It is said that 200 men will be employed.

Open for Alabama Agencies—The Snow-Tullis Hardware Company, 23-25 Commerce street, Montgomery, Ala., wishes to enter the automobile business. The company plans to sell both cars and a complete line of accessories, and will be pleased to receive propositions from manufacturers.

R. B. F. Bearings in America—The exclusive agency in this country for the R. B. F. ball bearings, made by the Société Française des Roulements à Billes has now been granted to the International Engineering Company, 1779 Broadway, New York City.

IN AND ABOUT THE AGENCIES

Stearns, Detroit—The F. B. Stearns Company will in the future be represented in this city by the Palmer Auto Company, of which Howard Palmer is the principal member. Headquarters have been established at 1221-1229 Woodward avenue. The company will handle the Stearns exclusively.

Jackson, New York City—The Jackson Motor Car Company, of New York, recently moved into its spacious new store at 1663 Broadway. The building was formerly occupied by the De Luxe representative, but has been considerably altered to suit the needs of the new occupant.

Miller Accessories, Atlanta, Ga.—Chas. E. Miller, the New York manufacturer and jobber of automobile supplies and accessories, has arranged to open a Southern branch in Atlanta on or about November 1, in time to supplement his exhibit at the show.

Elmore, Atlanta, Ga.—E. R. Clark has taken the agency for the Elmore, and has opened a show room in the northern half of the ground floor of the Masonic Temple, in the heart of the new automobile row. He is negotiating for a garage.

Standard, Haynes and Demot, Bainbridge, Ga.—The Caldwell Motor Car Company, of which C. H. Caldwell is manager, has contracted for the agencies for the Standard Six, the Haynes and the Demot in southwestern Georgia.

Chalmers-Detroit and Hudson, Nashville, Tenn.—Howard Cregor & Company, who hold the agency for the Chalmers-Detroit and Hudson, expect to open a salesroom at 135 Third avenue North this week.

Pullman and Baker, Houston, Tex.—The Imperial Motor Car Company expects to have its new salesroom at 1113 Prairie avenue open this week. It sells the Pullman and the Baker electric.

Fal-Car, Kansas City, Mo.—The Genung Motor Car Company has taken the old quarters of the Tebeau Motor Car Company at 1716 Grand avenue and will act as agent for the Fal-Car.

Hupmobile, Davenport, Ia.—The Dillon Auto Company has established itself in Petersen's garage, Fifth and Main streets, and will handle the Hupmobile.

Great Western, Kramer, Ind.—The Great Western Automobile Company announces that it has arranged with Joseph Rice to handle its cars in Kramer, Ind.

PERSONAL TRADE MENTION

J. B. McIntosh, for the past three years Michigan agent for the Lambert Automobile Company, has been appointed general agent for Lambert cars over a larger territory. The retail department of the J. B. McIntosh Company will be in charge of M. L. Hagle, a well-known automobile man.

R. S. de Mitkiewicz, member of the A. S. M. E., who was formerly with the Fairbanks Company, is now associated with the New York office, 115 Broadway, of the Alden Sampson Mfg. Co., Pittsfield, Mass., as expert in mechanical transportation.

H. E. Grant has been appointed treasurer of the Motor Company, the Philadelphia representative of the Premier. Mr. Grant was formerly the Philadelphia manager of the banking firm of Newberger, Henderson & Loeb, and is well know in business circles.

R. E. Fulton, the Eastern wholesale distributor for the Croxton-Keeton Motor Company, sailed for Europe on the *Lusitania* to look over the foreign situation on a three weeks' trip.

M. C. Huie, who has sold Ford cars in Atlanta, Ga., for several years, has been retained to act as the manager of the Ford Southern branch recently established in that city.

Harvey Goodwin has taken charge of the Stromberg Motor Devices Company, at 91 Church street. Mr. Goodwin was formerly with the Austin Automobile Company.

RECENT INCORPORATIONS

El Paso & Fort Hancock Railroad, El Paso, Tex.—Incorporated with a capital stock of $100,000, by R. Capler, C. E. Kelley, W. Cooley and others, of El Paso, Tex., to operate an automobile 'bus line between El Paso, Socorro and other towns in El Paso county.

American Aeroplane Company, Wilmington, N. C.—Incorporated with a capital of $125,000, to manufacture aeroplanes; F. A. Bissinger, president; C. W. Polvogt, vice-president; David Palmgreen, secretary; C. H. Dock, treasurer.

Spencer Motor Company, Rahway, N. J.—Incorporated with a capital of $125,000 by Charles G. Willis, of Brooklyn, N. Y., and Henry Albisser and A. G. Spencer, of Rahway, to manufacture automobiles and other vehicles.

Schroeder Aerial Navigation Company, New York City—Incorporated with a capital of $75,000 by Lindley B. Newby, George E. Fleming and Will H. Crow, all of New York, to manufacture balloons, dirigibles and aeroplanes.

Berkshire Auto Car Company, Pittsfield, Mass.—Incorporated with a capital of $120,000 by John McQuaid, Clement F. Coogan, and Hawkins, Ryan & Kellogg, all of Pittsfield, to do a general automobile business.

Brockton Rubber Tire Company, Brockton, Mass.—Incorporated with a capital of $50,000 by Wallace C. Flagg, C. G. Nelson and McLeod & Sweet, all of Brockton, to manufacture and sell rubber tires.

The Pilot Motor Car Company, Richmond, Ind.—Incorporated by G. E. Seidel, C. H. Kramer and H. M. Kramer, with a capital of $100,000, to manufacture automobiles.

TOLEDO OPENS GATES TO OVERLAND

Toledo, O., Oct. 11—One hundred of the most prominent professional and business men gathered in the Toledo Club to do honor to the Overland Automobile Company, the Kinsey Mfg. Co. and the Warner Gear Company, who have recently established themselves in this city, on the occasion of the welcoming banquet last week. Each of the tables in the club's big banquet hall carried a cluster of dark red asters, and above the sideboard the name "Overland" was spelled out in pink carnations. The banquet was one of the most notable social affairs of the nature ever given in this city. The menus bore on the front cover an open gate, behind which appeared the sky-line of the city, and the inscription: "Toledo—Open Wide the Gates." Speeches were made by J. N. Willys, president; W. H. Brown, vice-president; and F. A. Barker, sales manager of the Overland Automobile Company, and by Isaac Kinsey, president of the Kinsey Mfg. Co., and Thos. W. Warner, president of the Warner Gear Company, as well as by many prominent citizens of Toledo.

PACKARD PROGRESS CALLS FOR POWER

Detroit, Oct. 11—What is said to be the largest steam engine in the State of Michigan was turned on for the first time last Friday night at a power house banquet in this city, when President Joy officially opened the valve and threw on the switch which set the wheels of the Packard Motor Car Company's enlarged plant turning under the new power.

After the new engine had settled down to work, about thirty executives of the Packard company, the installing engineers and the Packard engineers sat down to a table spread in the engine room, discussed the new power plant, and swapped stories about the rapid growth of the Packard factory, which has necessitated a wonderful development of the power plant until to-day the three engines in service develop 5,000 horsepower. Another addition to the plant already has been started.

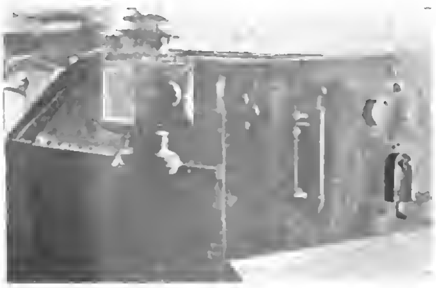
When the steam was turned into the new engine and the older one cut out, it was necessary for the untried monster to immediately take up the entire load. The engine is a Cooper compound of the Corliss type, direct-connected with a Western Electric generator. The bore of the low-pressure cylinder is six feet.

At the head of the table was President Joy and at his right and left General Manager S. D. Waldon and Manufacturing Manager C. J. Moore. The rest of the party comprised F. F. Van Tuyl, consulting engineer; F. C. Monroe, installing engineer; H. A. Hoagland, electrical installing engineer; Fred Willins, chief engineer of the Packard power plant; the assistant engineers and the executives of the Packard company.

Packard Executives Dining in Honor of Factory's New Power Plant

Information for Auto Users

Delco Ignition System—The Delco system of battery ignition is designed to provide a single spark for each charge of gas to be ignited, and thus avoid the waste of current that is inevitable in the usual vibrating-coil systems. The Delco



DELCO SWITCH ONLY PART ON DASH

system, which was brought out by the Dayton Engineering Laboratories Company, of Dayton, O., consists of four non-vibrating coils, a "controlling relay," which corresponds to what is commonly known as a master vibrator, and a special switch. The coils are built very compactly, and each unit is armored with a steel jacket, which protects it from water, oil and dirt. This enables them to be placed underneath the hood, close to the motor. The advantages of this location are numerous; the dash is left unobstructed, in compliance with modern

ARMORED COILS ARE UNDER THE HOOD

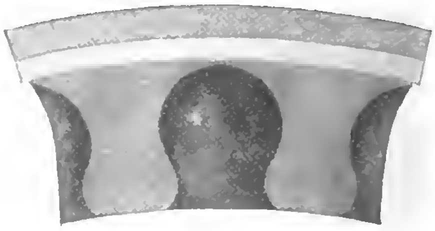
ideas as to the external appearance of the car, and wiring troubles are practically eliminated, because the wires may be made very short and direct. The circuit breaker, or "controlling relay," is also located under the hood, usually on the same bracket with the coils. This is the principal feature of the system, and its important points are covered by patents. It operates magnetically, and breaks the circuit the instant it is made by the timer, thus causing a single impulse of high-tension current from the coils and a single spark at the plugs. The switch is the only point of the system that is placed on the dash. It has the usual positions, battery, off and magneto—for a mcgneto may be used in the system instead of batteries, if desired. The switch has a push button connected with the contact-breaker which enables the car to be started on the spark. Six dry cells are commonly used with the Delco system, and on these a car can usually be driven 2,000 miles. The current consumption at low speeds is only .04 to .05 ampere, rising to .3 ampere at sixty miles an hour; it averages at about one-third the usual figure for the vibrating-coil system.

Airless Resilient Automobile Tire—Since so large a proportion of the expense, delay and trouble in operating an automobile arises from tires, a vast amount of time, money and thought have been expended in the effort to perfect a satisfactory tire. The National Airless Company, of Indianapolis, believes it has solved the problem with the Airless tire. At any rate, the tires are reported to stand the test of resiliency and, under some long runs at an average of 40 miles per hour, with a car of 3,000 pounds, the thermometer applied to the tires showed heat ranging from 72 to 84 degrees—whereas 200 degrees is the danger point. One set has been run over 15,000 miles by the Chicago Towel Supply Company and the company has reports on others that have ranged up as high as 12,000 miles without trouble. So good has been the showing made that the U. S. mail wagons operated by the Overland company in Indianapolis are being equipped with them.

SOLID PART OF AIRLESS TIRE

The construction of the tire is simple. The space occupied by the air tube in the pneumatic tire is occupied by globular cavities at close intervals, as shown in the second figure, which is a half-tone reproducing a photograph of a section of the tire sliced through the center. Each of these cavities has a circular outlet to the rim. This gives something of an umbrella shape to the solid rubber supports distributing the strains in every direction on the cantilever principle.

A glance at the first figure will show that the solid part of the inner construction does not reach the rim. A continuous air passage is left at the bottom of the tire, affording entire freedom of air circulation. After this inner part is molded, the tire is built up of layers of



INTERNAL TRUSSES GIVE STRENGTH

fabric and rubber just as are the best pneumatic tires, and it is all cured together, making one homogeneous whole. Thus there is entire absence of friction. The tire generates no more heat in running than does a pneumatic with either a reline or a tire protector.

Don't Get Cold Feet—For the man, woman or child bothered in winter or other cold weather driving, nothing makes such a hit as a foot warmer. Many of these are complicated, expensive, and costly to maintain. The new series of heaters just brought out by the Chicago Flexible Shaft Company, La Salle avenue and Ontario street, Chicago, under the names of Dutchess and Clark, do not possess any of these defects, in that they are simplicity personified, of medium price, and the cost to use is very low. These heaters are made in nine sizes, varying in price from the lowest, at $1.25, up to the de luxe type, the Dutchess, at $10. Each one of them is made so as to surround an inner compartment which is lined with or filled with asbestos to retain the heat as long as possible The one end has a drawer which may be withdrawn at will and within which the fuel, as it is called, may be placed. This fuel is a very important part of the heater, although supplied separately. It comes in small, compressed cakes, and throws out an intense heat, without flame, smoke or odor, and moreover leaves very little residue. By wholesale buying, the price of the heat is reduced as low as two cents per ordinary drive and lower. Despite the remarkably low price for the heater, and equally low cost of operation, every heater and every brick of Clark coal is carefully inspected and the ensuing product guaranteed on a money back if not satisfied basis.

"TO THE SUNNY SOUTHLAND!"

How Georgia Is Making Roads

IT was a by no means easy task for the promoters of the "National Highway"—the New York *Herald* and the Atlanta *Journal*—to select the route of the good roads endurance tour to the Gate City of the South. For other important tours held in this country fairly definite data as to the best roads have been available, and the only requisite has been to send a pathfinding car over the established route to compile specific road directions. But no sooner had the two newspapers announced their scheme of a New York-to-Atlanta highway, when advocates of different routes started to overwhelm the promoters wtih conflicting claims to superiority.

Obviously there was but one way to decide which route was the best—namely, by actually testing all of them. To that end, a White Steamer, during the Summer months, made three trips of inspection between New York and Atlanta, covering as many different routes. The first trip was over the "Shenandoah Valley-Southern Railroad" route; the second trip was over the "Capital-to-Capital" route via Washington, Richmond, Raleigh and Columbia, and the route covered on the third trip coincided with the first as far south as Roanoke, and then turned southwesterly through a section of Eastern Tennessee but little known, by way of Bristol, Knoxville and Chattanooga.

After this thorough examination of all possible routes, one was decided upon and mapped and mileaged by the writer; more than 2,000 signboards have been placed along the roads, and all is now in readiness for the first touring contest between North and South, which, beginning on Monday next, October 25, will "inaugurate" the new highway between the Metropolis and Atlanta.

Those who made the three "scouting" trips were unanimous in the decision that the first route was the best, and, accordingly, the

White Gasoline Car Found This Good Stretch of Road Near Summerfield, Va.

White pathfinders on their recent trip covered, for the most part, the same roads as were followed on the first trip of exploration except that between Roanoke and Charlotte an entirely new route was marked out via Rocky Mount, Martinsville, Winston-Salem, Greensboro and Thomasville. The accompanying map shows the "National Highway" as finally determined upon.

Inasmuch as the pathfinders traveled over many miles of road which they had covered four months before, they were able to see the tremendous improvement which had taken place in the interval, this advance being due in no small measure to the active propaganda which has been carried on by the two daily newspapers most interested in the tour. A case in point is that of York, Pa. When the White "scout" car passed through this prosperous city last May the main street was full of holes and ruts and compared but poorly with the macadam pikes which lead from that city out into the farming districts. The city was properly "roasted" in the news and editorial pages of the New York *Herald*. The local York paper reprinted these criticisms, and the outcome of the agitation was that the city voted an appropriation to pave the main street. When the pathfinders went through York two weeks ago they found as fine a brick pavement as could be desired.

While driving the pathfinding car between Staunton and Roanoke, I found it necessary several times to alter my road directions to read "Cross iron bridge over creek," to replace a reading of "Ford creek," which I had made on the trip last May.

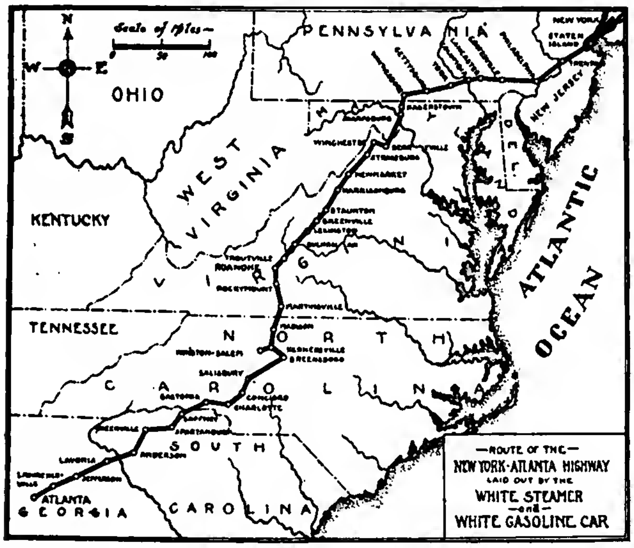
And now a few words about what is being done on the roads between Roanoke, Va., and Winston-Salem, N. C., as the narrative will illustrate how far-reaching have been the results of the recent good roads campaign. Winston-Salem was not visited on any of the three "scouting" trips, and it looked to the citizens of that thriving community as if the rival town of Greensboro, 35 miles away, was to wrest away the honor of being on the "National Highway." "Why are we left out?" inquired indignant Winston-Salem of the promoters of the enterprise. "Because the roads from Roanoke to your city are the worst ever," was the reply. "Then we will fix them," rejoined Winston-Salem, followed by a spectacle which, I believe, has no precedent. A mass meeting was held in Winston-Salem and with great enthusiasm several thousand dollars were subscribed by private parties to be spent on the roads of *another state!* But that was not all Winston-Salem did in its eagerness to be on the "National Highway." It was pointed out that even if the road leading south from Roanoke was improved it might still be possible that the route would go to Greensboro direct and leave Winston-Salem out. "Well, we will fix that, too," said Winston-Salem. Accordingly the town officials got busy and started construction work on three miles of entirely new road, thus building a "cut-off" which makes Winston-Salem logically and naturally on the New York-to-Atlanta highway as planned and mapped.

Fairly good roads are found almost all the way from New York to Roanoke, but it is probable that those who take part in this month's New York-to-Atlanta tour will not soon forget the sixty miles of mountainous roads south of Roanoke. The difficulties of the road may be judged from the fact that, although a large delegation of autoists drove out to meet us on our way into Roanoke, not a single driver was willing to show us the way south from Roanoke the next day. However, the president of the Roanoke Automobile Club, J. H. Marsteller, kindly offered to ride in our car and act as pilot. Mr. Marsteller is the most active motorist in that section, and yet he had never driven southward over the road leading from Roanoke.

The first stretch of 28 miles, from Roanoke to Rocky Mount, required 2 hours 40 minutes to negotiate. Perhaps fifteen minutes was spent in taking photographs and inquiring the way, but the balance of the time we were going as fast a pace as the road would stand. It is up hill and down hill—up and down without cessation. The road twists and winds around the mountainsides so one can rarely see what awaits him 50 feet ahead. The turns are very sharp and one comes unexpectedly to short grades as steep as

Roads Are Generally Excellent on the Popular Shenandoah Valley Route any on Giant's Despair at Wilkes-Barre. Add to this that the road is rough and rocky, and one can understand why we did not average more than eleven miles an hour with a car ideally adapted for just such road conditions. The wonder is, not that the road in this section is so bad, but that it is as good as it is, for the country is almost entirely deserted. There are no farms, no pasture, and no traffic. It is on this stretch of road that the money raised in the North Carolina city of Winston-Salem is to be spent. Already some work has been done in leveling off the rocks which project into the road and in filling up some of the holes. By the end of the month it may be a fairly decent road over which to drive a car. From Rocky Mount to Martinsville conditions improve somewhat, so that a schedule of 15 miles an hour may be suitable for the large cars in this month's tour.

The Scenery Is Picturesque Near the Piedmont Toll Bridge



North Carolina, as I have said in previous articles, has been leading the "New South" in the building of good roads. There are numerous fine straightaway stretches of flawless macadam where, for miles at a time, one may drive a car at its maximum speed wtihout any fear of accident, as cross-roads are few and far between and traffic is light.

South Carolina has been doing wonders during the last few months in improving its dirt roads, which are the prevailing type in this State. The roads are, for the most part, smooth, well graded, and without sharp turns. In dry weather splendid time can be made in crossing this State; in wet weather the tourist had better provide himself with three or four sets of tire chains and postpone his other engagements for a day or two.

Georgia, the pathfinders found to be literally torn up by gangs of convicts engaged in resurfacing the road. The counties are vieing with each other in bonding themselves to build new highways, and the good roads enthusiast may say of this State: "Not yet, but soon."

At the present writing, nearly a half hundred cars have been entered for tbe tour. A noteworthy feature of the entry list is that more than two-thirds of the cars have been entered by private owners from the South. Some of these latter entries are to represent the boards of trade or chambers of commerce of various cities along the line. The rules of the contest are of the simplest possible sort, merely requiring the cars to travel on a definite schedule, with no questions asked regarding repairs or replacements; but no time is allowed for repairing tires and the contestants must do their filling, oiling, etc., on their own running time. Whether the contest will appear to be a tour or a "road race" to those making their first appearance in competition is a question which only time will decide. However, one thing is certain—after the tourists cross Mason and Dixon's line they will be welcomed, dined, fêted, and "barbecued" in every town where a noon-stop or night-stop is scheduled, and unless the tourists have a different experience than did the pathfinders, they can ship their pocketbooks home as superfluous baggage after entering the Sunny South.

Colored Road Workers Are Healthy, Busy, and Happy

WHAT LIES BETWEEN SAVANNAH AND ATLANTA

SAVANNAH, GA., Oct. 18—Shortly after 7 o'clock on a recent October morning, the scout pathfinding car, a Chalmers-Detroit, set out upon its 300-mile journey from Savannah to Atlanta to pick out the route for the endurance run to be held November 8.

The car started from the T. A. Bryson garage, going through the following towns on its way to Milledgeville: Pooler, Edam, Stilson, Brooklet, Statesboro, Sandersville, and then to Milledgeville for the night. This place was reached at 6.30 o'clock in the afternoon, after a good run. There being no record driving to see how quickly the trip could be made, the work consisted solely of photographing and obtaining route information for the run.

The first stop was made at Louisville, where a big reception was given to the party, and similar ones followed in Sandersville and Milledgeville. In each town the county commissioners and mayor would come out and greet the car, and would sign the pledge to help to boost the good roads movement that has just now set this part of the country wild.

At Louisville a big spread was supplied, and after this the Savannahians were taken for a ride to the boyhood home of President Battey of the Savannah Automobile Club. At this place a battle took place between the auto crowd and a rattlesnake, in which the snake lost its life.

At Sandersville the party was met by Mayor Evans, who served as guide. Leaving here, the party was met half way by Mayor Bell, Milledgeville, who escorted the procession to that place.

The best roads on this part of the journey were found in Jefferson, Washington, and Baldwin counties. The roads in Jefferson county are already complete and in good condition. In Baldwin county large hills have been cut away to make the road. The roads in Washington county are torn up a little because they are beginning to grade them for the run. Other good roads were found in Burke and Jenkins counties, but these were a little sandy because of the lack of rain for several days. The time between Savannah and Milledgeville was 9 hours 10 minutes, the distance being 108 miles. At Millen, Sandersville, and Milledgeville gasoline stations were established for the run.

Putnam County Had Poor Roads

Road Building in Jenkins County

Near Millen, in midst of Sugar Cane

After staying overnight at Milledgeville, the party left at 8.30 the next morning with James L. Sibley, postmaster, as leader for the entire run to Atlanta. The following cities were visited and in each a big reception was given to the car: Eaton, Madison, Social Circle, Covington, Lithonia, Redan, Stone Mountain, and Dictur.

The trip from Milledgeville to Atlanta was made in eight and a half hours, but four of these hours were consumed in stops on the way. The roads in Putnam were found excellent, which made the running most enjoyable. In Morgan county the roads became poor. At Newton the commissioners are still working on the roads, but will have them in shape for the run. The roads of Dekalb county were rough, but will soon receive attention.

At Lithonia a party of Atlantians met the pathfinding party, among them being Col. J. R. Grinn, of the Atlanta Automobile Association; Police Commissioner C. Mason; H. L. Wilson, of the General Motor Works; C. R. Tyce; T. I. Ryan, of the Fourth National Bank; Chairman Whiting, of the reception committee, and J. F. Lewis, of the Atlanta *Constitution*.

Arriving in Atlanta, the car was taken through Peachtree and Whitehall streets, and then to the Atlanta

Automobile Association clubhouse, near Hapeville, via Stewart avenue. The odometer showed that on arriving in Atlanta the car had travelled 289.8 miles during the whole trip.

On the return to Savannah, the car left Atlanta Thursday morning, taking the old Capitol route. It is said that between thirty and fifty cars will participate in the run and try to capture the large prizes that will be presented.

The night stop on the run will be in Milledgeville, which will be reached about 6 o'clock in the evening. The cars will be divided as follows: Class C, cars costing $1,250 or under, speed of 15 miles an hour; Class B, cars costing $2,000 down to $1,250, speed of 15½ miles an hour; Class A, cars costing over $2,000, speed of 16 miles an hour.

The following cars were entered up to last Saturday: Three Packards, three Stevens-Duryea, two Chalmers-Detroit, two Cartercars, one Crawford, one Acme, one De Tamble, one Buick, one White Steamer, one Cadillac, and one Reo.

NEW YORK TO BIRMINGHAM

BIRMINGHAM, Ala., Oct. 17—The Interstate Good Roads Convention passed the following resolution:

Be it resolved by the Interstate Good Roads Convention now in session at Birmingham, Ala., That the suggestion of the Birmingham Board of Trade is hereby commended for an automobile route between Birmingham and New York by way of Chattanooga, Knoxville, Tate Springs, Bristol and Stanton, following the valleys between Appalachian ranges and not crossing the mountains.

VANDERBILT ENTRANTS ARE PRACTISING ON COURSE

PRACTICE over the Vanderbilt course on Long Island was scheduled to begin Monday morning; the 22 special flagmen were on duty, and all traffic was carefully diverted to other roads during the prescribed hours, from 5 to 8 a. m. However, the flagmen and several hundred spectators gathered at Hicksville were all disappointed, for not a single car appeared. It was learned afterward that most of the drivers had planned to begin Wednesday, sacrificing two days in order to have their machines prepared for fast work as soon as they were brought out. The corps of flagmen demonstrated their efficiency, however, and, viewed as a little private practice for their benefit, the day's work was a great success. Wednesday morning the daily practice work had its beginning.

The course has already been brought into very fair condition. The oiling and the banking of the corners has been completed, and all of the holes and ruts in the country roads have been filled in with the best of Peekskill gravel. Only a few rough spots remain to be rolled down. Manager Pardington has prepared special number plates which will be hung on the radiator of each practicing car, and none of these numbers will be issued except to *bona fide* entrants who have paid their entry fees. In order that the spectators may identify the cars, it has been arranged that those entered for the Vanderbilt Cup proper will carry numbers 1 to 29; those entered for the Wheatley Hills Sweepstakes will be numbered from 30 to 39, and those in the Massapequa Sweepstakes from 40 to 49. These numbers are only provisional, however, the numbers in the actual race will be drawn for later, although the system will be the same.

The policing arrangements, it is expected, will be a great improvement over previous years. Sheriff Joseph H. Foster, of Nassau county, has organized a large force of men who will be posted at the police and flag stations, marked by a yellow placard and numbered consecutively. Acting in conjunction with the sheriff, the Pinkerton detective agency will have about 400 picked uniformed men on duty. This force is to be drawn from all parts of the country, and most of them will be men who have seen duty in strikes and riots in various cities. Those who remember the Vanderbilt crowds of former years will agree that such experience will stand them in good stead. All of these men will he sworn in as peace officers, will wear caps and sheriff's badges, and will be provided with police night-sticks, which they are instructed to use if necessary. Flagmen, deputies, and Pinkerton men will be placed at an average of about 100 feet apart around the whole course. The management will endeavor to keep the course clear until at least five cars finish.

The box-office reports are extremely promising, and an extra force of men has been working at the headquarters, Forty-third street and Broadway, sending out the pasteboards. The grandstand contains only about 5,000 seats, and from present indications double that number will hardly satisfy the demand. One-quarter of the 300 boxes have already been sold. The arrangements for reserved parking space, which caused some dissatisfaction last year, have been altered so as to insure a satisfactory view of the competing cars as they approach and pass.

Twenty-two entries have been received at present.

Four Chalmers-Detroit cars will participate, their pilots being the veteran team, Lorimer, Dingley, Matson and Knipper. They have rented a house in Garden City as headquarters.

The foreign contingent is represented by two Fiats, one of which will be in charge of Hearne, the young Chicago amateur, and the Isotta, which finished second last year, to be handled by Joe Seymour.

George Robertson may drive one Simplex and another of the same make is also entered.

Others are the Alco, H. F. Grant; the Apperson, Hugh Harding; the Marion, George Riess; two Buicks, in charge of Chevrolet and Burman; two Nationals, to be driven by Merz and Aitken; a Moon, an American, two Marmons and three Maxwells.

The entry list does not close until September 25, but late entrants will have to confine their practice to the Motor Parkway, as the county supervisors have announced that they would not issue permits after last Monday. Renault, Stoddard-Dayton, Knox, Rainier, and Sharp-Arrow are still expected to appear at the starting line.

The race starts at 9 a. m., October 30. The distance for the Vanderbilt Cup contestants classes 1 and 2 is 278.1 miles, 22 laps of the 12.6 mile course. The Wheatley Hills Sweepstakes, for class 3, will go 15 laps, 189.6 miles, and the Massapequa Sweepstakes, for class 4, 10 laps, equal to 126.4 miles.

NO. 13 PACKARD, FLETCHER DRIVING, WINS BRAZIER CUP

PHILADELPHIA, Oct. 16—High winds, chickens and the number 13 played a prominent part in deciding the winner of the seventh annual renewal of the Brazier cup contest, that pioneer among automobile competitions promoted annually by the Automobile Club of Philadelphia.

There were thirteen contestants, and car No. 13, G. B. Fletcher's Packard, won with just exactly 13 points penalty against it. The trail over the 65-mile course, which wound rather aimlessly over the excellent country roads in Montgomery, Bucks and Philadelphia counties, in juxtaposition to the city, was laid with confetti and corn. That was where the high wind and the chickens came in, for whereas the former lifted the flimsy paper and whirled it into the beyond, the latter camped on the trail during the hour or more that elapsed between the passage of the pilot car and the arrival of the first contestant, and devoured every scrap of evidence! The result was that many of the contestants lost their way and had to return. On one stretch—that tbetween Conshohocken and Neshaminy, where the wind was either exceptionally high or the fowls particularly hungry, or both—no less than nine of the cars went astray.

Fletcher was among the few lucky ones and lost little or no time by missing the way. He accumulated his lucky 13 demerits by passing the hidden checkers either ahead or behind his official time. These checkers were secreted at several points unknown to the contestants and registered the time each car passed them. These lists were then compared with the times each car should have passed the several points, and any variation meant one point for each minute out of the way.

C. Yarnall Abbott, in a Pennsylvania, was second, with 23 demerits; Alan Wood finished third with his Pope-Toledo, accumulating a total penalization of 28½ points, and W. C. Longstreth, Pullman, captured fourth place with 39½ bad marks. The other contestants were: Alan Corson, Buick; Henry P. Baily, Winton; P. M. Elsasser, Winton; J. H. Schenck, Jr., Winton; G. M. Sailer, Packard; W. Stewart Harding, Autocar; George D. McCreery, Jr., Buick; E. C. B. Fletcher, Packard; D. Walter Harper, Stanley steamer.

The majority of the contestants had their families with them and the affair was voted a delightful social success. One of the rules required that the owner drive.

This being the third win for Fletcher, the Brazier cup becomes his permanent property. It is whispered that he may return the cup to the club for further competition; otherwise the most ancient of annual fixtures may be missing next year.

Line-Up of Brighton's Record "24": No. 4 Lozier (2d); No. 3 Lozier (1st); No. 9 Rainier (3d); No. 10 Marmon (5th)

BRIGHTON BEACH'S concluding 24-hour race of the season had record speed and a Lozier six-cylinder winner, with another car of the same make as the runner-up. Swept by ocean breezes in late October, the Brighton track did not present an inviting appearance, with the result that the crowds of previous 24-hour races failed to gladden the hearts of the Motor Racing Association officials in the interval between 8 p. m. Friday and 8 p. m. Saturday. But neither the weather nor the absence of spectators prevented the demolishment of the American one-mile circular track records, and the course evidenced much improvement and presented a reasonably smooth surface.

The winning Lozier accumulated a mileage of 1,196, which was an improvement of 19 miles over the previous record of Robertson and Lescault, made with the Simplex in October, 1908.

Mulford and Patschke formed the winning combination of drivers, with Cobe and Seymour in charge of the other Lozier, which traveled 1,169 miles and excelled anything previously done on Brighton track this year. Both cars used Diamond tires.

The starting line was graced by the presence of Dr. Frederick A. Cook, of Arctic fame, who for the occasion wielded the official pistol. The nine cars got away to a straggling start and were strung around the track before five miles had been covered. Chevrolet took the lead for ten miles.

Then the Palmer-Singer, with Howard at the wheel, gradually worked ahead and held the lead until the twenty-fifth mile, when Chevrolet again got ahead. The Buick driver kept up his fast pace until he had set new records for one and two hours. Burman with the second Buick was now in second place, and soon after succeeded in passing his team mate, himself making the record for the third hour. Chevrolet had trouble and Seymour and the Lozier slipped into second place.

The first accident occurred before the completion of the first hour. As Cobe drove his Lozier into the homestretch a rear tire flew off and struck him on the head. Cobe was half stunned, but kept control. Seymour took his place after the car had lost nearly a lap. Soon after midnight the Palmer-Singer got into trouble. As this car, with Lescault at the wheel, was rounding the turn into the homestretch its front wheel came off and hurtled into a group of spectators. It struck Miss Alice Roberson, of Brooklyn, fracturing her collar-bone. Lescault handled the car well and brought it to a stop without any further serious results. It resumed racing as soon as another wheel was put on.

The Rainier Company for this race had placed its two star drivers, Disbrow and Lund, on the same car, and had entrusted its second entry to Wally Owen and Charles Bowers. At 6:45 in the morning, Bowers driving, the Rainier's right rear tire burst on the clubhouse turn, and the car went through the fence, turning over twice. Bowers sustained a fractured skull, but will probably recover.

Louis Chevrolet began to have his troubles soon after estab-

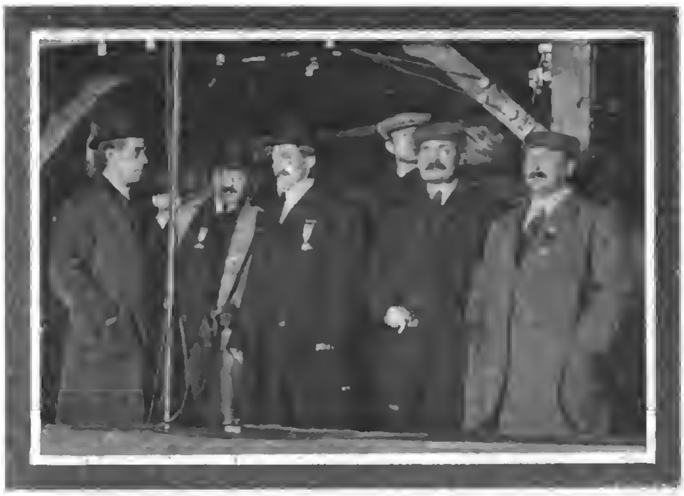
Note—Heavy faced figures indicate new and existing records.



Polar Explorer Who Started All the Trouble
Dr. Cook and a Number of the Other Officials of Brighton "24"

lishing a record for twelve hours. At 10:45 in the morning his rear axle snapped, and the frame was bent by the resulting shock. Repairs were made, but about an hour later Louis' brother, Arthur, who had taken the wheel, went through the clubhouse fence and struck a tree. Driver and mechanic were hurled twenty feet through the air, but escaped injury. The car was wrecked. A little after noon the steering gear of Lozier No. 4 went wrong, and the driver had to ditch the car to escape a collision. Little damage was done, and the Lozier was soon back on the track. About the same time James, driving the Marion, took the far turn so fast that his car skidded and turned completely around. The officials decided that he was incompetent to drive, and put a man named Flanagan in his place.

A special prize of $200 had been hung up for the greatest mileage made in the last hour of the race. This was at first believed to have been won by Buick No. 5, but at a later meeting of the M. R. A. it was announced that this prize, too, had been taken by Lozier No. 3. Owing to the fact that all the cars were permitted to cross the finishing line after the 24 hours had elapsed, the Buick was at first credited with one mile too much. The Lozier made 51½ miles.

Ralph Mulford, one of the winning pilots, was married Friday just before the race started. The wedding day had been fixed at the time the race was scheduled for September 24, and when the race was postponed he refused to change the date of the happy event. He and his bride will start on their honeymoon with the $1,000 cash prize and a bonus added by the Lozier Company.

FAIRMOUNT WINNERS RECEIVE PRIZES

Philadelphia, Oct. 18—There was a veritable love feast of gratified Quakers at Keith's Theater last Thursday night when the prizes won in last Saturday's 200 mile Fairmount Park race were distributed among the victors. The big playhouse was jammed, and after witnessing the rerunning of the main features of the race on the moving picture machine, Starter G. Hilton Gantert was introduced by Manager Jordan, of the theater. Gantert "started" Referee R. E. Ross, and the latter in a neat speech presented Harry C. Harbach, secretary of the Quaker City Motor Club, in whose fertile brain was hatched the idea of having an annual race in Fairmount Park, and to whose untiring labors no little of the success attending the event during the last two years can be attributed.

To Mr. Harbach fell the pleasant task of presenting the prizes to the winners. Robertson captured $2,500 in gold and the $1,000 MacDonald & Campbell cup; Dingley annexed $1,250 in cash and the Autolight Company's gold watch, the latter for the most consistent work during the race; Harding, $750 in gold, and Joe Parkin $500 in the same yellow metal. The big, good-natured crowd insisted on speeches from each of the winners, but the latter were evidently out of their element, and the few words they uttered in response were hardly audible. Len Zengle, who was awarded $100 in gold for the fastest lap (7:41), did manage to express his regret that he hadn't made all his laps in that time, but the elocutionary efforts of the others were not impressive. Numerous speeches, however, followed by representatives of the four institutions which profited from the proceeds.

POINT BREEZE MEET WAS DISAPPOINTING

Philadelphia, Oct. 16—The combined "land and air" speed exhibition which was to have come off on the Point Breeze track this afternoon did not pan out according to expectations. The land end of the program came off all right, although the speed was not all that could have been desired, but the Curtiss aeroplane, in charge of C. F. Willard, which was to have given the Philadelphians their first view of modern aerial navigation, was prevented from spreading its wings by a howling gale which swept over the field. "I would be in the Delaware in two minutes if I went up in this gale," said Willard. So the 6,000 spectators, the majority of whom had come purposely to witness the first exhibition in this city, were disappointed.

The races were of the most perfunctory order, and were strung out in an effort to keep the crowd quiet until Willard could appear. In a best two out of three, five-mile heat match race, George Robertson and his Simplex were beaten in straight heats by Willie Haupt at the wheel of a six-cylinder Thomas. The times were 5:55 and 5:44. Robertson had his revenge in the five-mile free-for-all, which he won in 5:37, with L. J. Bergdoll and a Thomas second, and Haupt bringing up the rear. In a filler event Bergdoll beat Haupt two straight five-mile heats. A series of mile record trials netted 1:05 for Robertson, 1:08 for Haupt and 1:10 for Bergdoll. The promoters will endeavor to keep faith by having Willard later.

NEW NATIONAL FORTIES IN VANDERBILT

Indianapolis, Oct. 16—Two of the new National "Forties," of which the specifications have just been published, are entered in the Vanderbilt Cup race. These cars have four cylinders, 5 by 5 11-16 inches, double ignition with Bosch high-tension magneto and storage battery, a three-speed selective gear, shaft drive, 124-inch wheelbase and 36-inch wheels. This model during the present year has sold for $3,750, but for 1910, in spite of the longer stroke and the lengthened wheelbase, the price will be cut to $2,500. On the Indianapolis speedway these cars showed a speed of better than a mile a minute. John Aitken will drive one of the Vanderbilt cars, and either Merz or Kincaid the other.

Up-To-Date Accessory Features of Radiators and Pumps

By Thos. J. Fay

Part 1

Fig. 1—McCord System of making tubing from long ribbons of sheet brass, at a rapid rate and well, with a seam which adds strength

ACCESSORIES are made in separate shops to a vast and growing extent and assemblers of automobiles depend upon these specialists for much of the excellent results realized. Even the makers of automobiles who bend every effort to build as much as possible of the whole car under one roof go to accessory makers for such units as radiators, oilers, the ignition system, and tires.

Parts makers, then, are of great and growing importance to the well being of the industry, and it has been shown that, as a rule, these specialists make as good, if not a better, showing than is frequently indicated by shops in which the attempt is to cope with the whole problem in diversified form, it being the case perhaps that "a jack of all trades is a master of none" in this as in other walks in life.

Logic and Truth Not Always Parallel—The "farming-out" process has its faults, among which lack of interchangeability is uppermost. In any attempt to reason that all parts if made outside will lack in this quality, basing the reasoning on the results attained from the farming-out process, a fallacy will be concealed. There is a vast difference between farming-out parts of units and purchasing a whole unit from a regular maker of the same. A crankshaft, for illustration, is but a part of a unit (the motor) and if it is farmed out when it is made it may not fit into place. A radiator, on the other hand, is a whole unit; it is delivered complete; the limits of tolerance, involving its fit in the chassis, affords an ample range of variation and there is absolutely no reason why the whole unit may not be made in a plant devoted to radiators and when delivered, fit in the chassis to the entire satisfaction of all concerned.

What the Practice Is in One Shop—In the respective plants there are bound to be differences in methods, and in a general way, owing to changing types of equipment and on general grounds, it may be necessary to describe the process in each plant in order to see the whole situation. In the main, however, from the user's point of view, a good understanding of what it means to build accessories will be gleaned if the process in some one plant is illustrated and described. For this purpose the plant of the McCord Manufacturing Company, at Detroit, Mich., has been selected and Fig. 2 is of the regular form of McCord radiator showing the front at A and B is of the other side. This type of radiator is used on cars when a pump is provided for purposes of water circulation. The radiator shown in Fig. 3 differs from the one in Fig. 2 in important particulars; it is for thermo-syphon work, but as a thermo-syphon radiator it is a special form as used in Regal cars made by the Regal Motor Car Company, located at Detroit, Mich. These radiators are of the vertical-tube type, in which rows of brass tubing disposed vertically, the same 1-4 inch in diameter, are nested with about 24 tubes to the row, the exact number differing in the different cars, depending upon the distance across, and the number of rows used is regulated by the motor requirement. In the Hudson car, for illustration, which is the car on which the radiator, as shown in Fig. 2 is used, there are three rows deep and 24 tubes to the row, making in all 72 tubes in the radiator. In the Regal "30" the radiator, as shown in Fig. 3, has five rows of tubes and there are 25 tubes to the row, making 125 tubes in all.

In order to increase the radiating surface of the tubes they are nested in a set of horizontal flat plates, of which there are enough to reduce the spacing or pitch of the plates to about 1-4 inch. The tubes are made of brass by a process, as shown in Fig. 1, by a machine which takes a spool of brass ribbon in at one end and delivers tubing the length of the ribbon at the other. It is a simple and rapid tube mill which reduces the ribbon to tube formation, a section of which is shown in Fig. 4.

After the tubing is made it is cut to lengths and dipped in a bath of solder, as shown in Fig. 5, when it is ready to go to the assembling process which requires the use of a machine, as shown in Fig. 6; its function is to press the flat plates over the nest of tubes. The tubes are held in a form while the work is

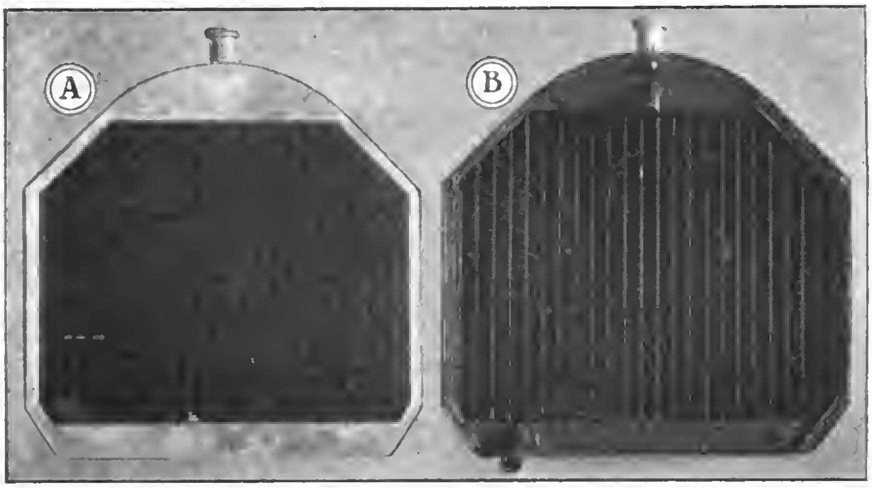

Fig. 2—McCord type of radiator as used on Hudson cars, designed for water circulation with a pump

being done and the holes in the plates are so sized that the tubes press tightly against the metal of the plates with results, as shown in Fig. 7, and the metal of the plates is turned down, thus increasing the surface of contact several hundred per cent. and the efficiency of the radiating surface to a vast extent.

Soldering Increases the Effectiveness—While it is true that the soldering process through which the tubes are put is a safeguard as against any possible leak, the fact remains that the tubes are tight, almost without exception, as they come from the tube mill and the solder has a more important function to perform. When the assembly is made by use of the press, as shown in Fig. 6, the whole is taken to an oven and heated to a temperature sufficient to melt the solder. Since the radiators are placed in the heater with the tubes in the vertical, it follows that the solder runs down and forms fillets at the junctions of the plates, as shown in Fig. 8, and the section of conducting metal at the point of contact of the plates with the tubes is increased very materially and the radiating effect is therefore vastly increased.

In order that the front of the radiator will look uniform and take on an artistic appearance the plates as used are fashioned with a wire binder, as illustrated in Fig. 9, which is enlarged to bring out the point to be made. The binder is in the shape of a length of wire which is turned under and acts as a stiffener for the plates, which, in the absence of this binder, would scarcely offer an adequate measure of rigidity.

When the internals of the radiator are made much as shown in the illustrations it is a simple matter to slip them into their casings and after soldering them they are subjected to a test to determine if there is a leak or a mechanical weakness at any point. For the rest it is a matter of finishing in black enamel for the tubes and plates and laquer over the remaining bright surfaces.

The finished radiators are light, strong, and in view of the unquestioned quality residing in them, it is interesting to note that this same quality would be at much extra cost were it not for the special processes employed. Many of the important details are omitted from the discussion since they are of little interest excepting to the maker, it being the idea here to show that quality is only possible (at a reasonable cost) if special processes obtain and it is needless to say that these methods did not come in a day and must have resulted after the expenditure of a pretty penny suitably mingled with skill.

Conditions as Demanded in Practice—The ability of any radiator is absolutely independent of the motor on which it is placed for the purpose of absorbing the heat from the jacket water. This fact is sometimes lost sight of and comparison is frequently made on a basis that leads to wrong conclusions. When it is desired to ascertain the required capacity of a radiator for a given motor it is first necessary to determine definitely the amount of heat that must be absorbed from the jacket water, and as should be well understood, this is a matter that depends upon the design of the motor and not upon the radiator.

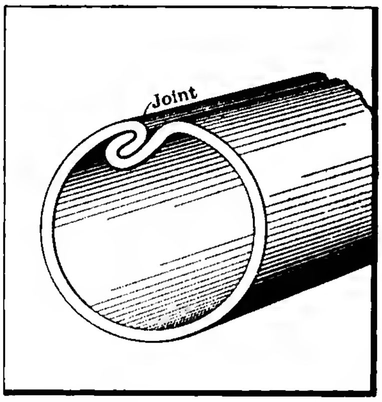

Fig. 4—Section of tube as made in McCord mill, showing how seam is overlapped and flattened down

In view of this and other conditions of more than a little importance, the McCord plant is equipped to investigate the whole situation for makers of cars in order to ascertain the best capacity of radiator to adopt in a given case. In the regular way it has been found that there are three conditions to be satisfied in the main, as follows:

(A) When motors are of the water-cooled type and a pump is used to maintain the circulation of water on a suitable basis.

(B) When the thermo-syphon system of water cooling is adopted under the conditions as here indicated.

(C) Considering the flame-swept surface in motor cylinders.

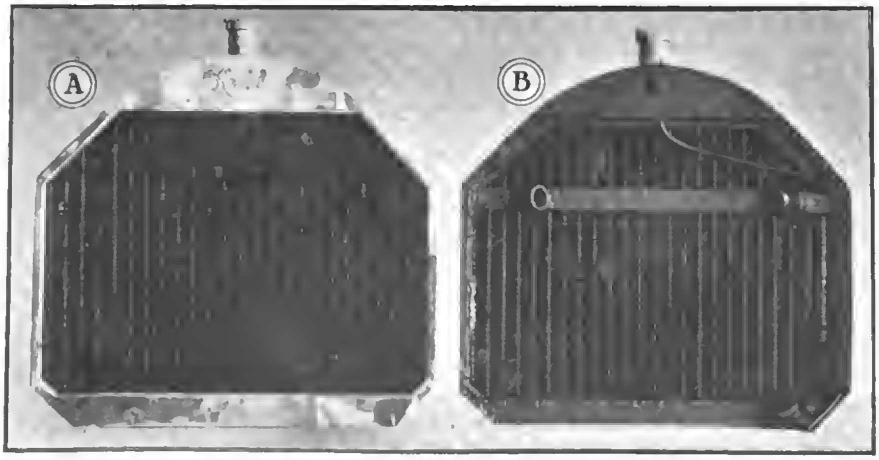

Fig. 3—Regal type of thermo-syphon radiator, utilizing energy of steam to add to circulation of water

Water Cooling Has Certain Limitations—There is a point beyond which the increased circulation of water adds but little to the result. This limitation is due to one of three considerations or a combination of them, viz.:

(A) Limiting value of air circulated over radiator surfaces of cylinders and radiators.

(B) Lack of ability of the water to take up heat from the radiator surfaces in direct proportion to water circulated after the speed of the water reaches a certain velocity.

(C) Effect of deposits of foreign substances over the surfaces brushed by the water.

It is perfectly feasible, of course, to do without a water pump if the ratio of flame-swept surface to radiator surface is properly adjusted. Under the circumstances it is one of the safe conclusions that the flame-swept surface of a cylinder should be reduced to the lowest possible value in square inches in comparison with the piston displacement in cubic inches. This is a matter which depends largely upon the shape of the dome of the cylinder, it being the case that a hemispherical dome is the most efficient for the purpose.

If in a given motor it is true that the flame-swept surface is very great in comparison with the cubical displacement or horsepower of the cylinder, it will be a showing of wisdom on the part of the designer to adapt a water pump for purposes of circulation, and even then it will be wise to use a radiator of large capacity. Obviously, the amount of heat that the radiator will have to dissipate will be relatively large, since the flame-swept surface will be such that much heat will escape to the jacket water, requiring increased radiation.

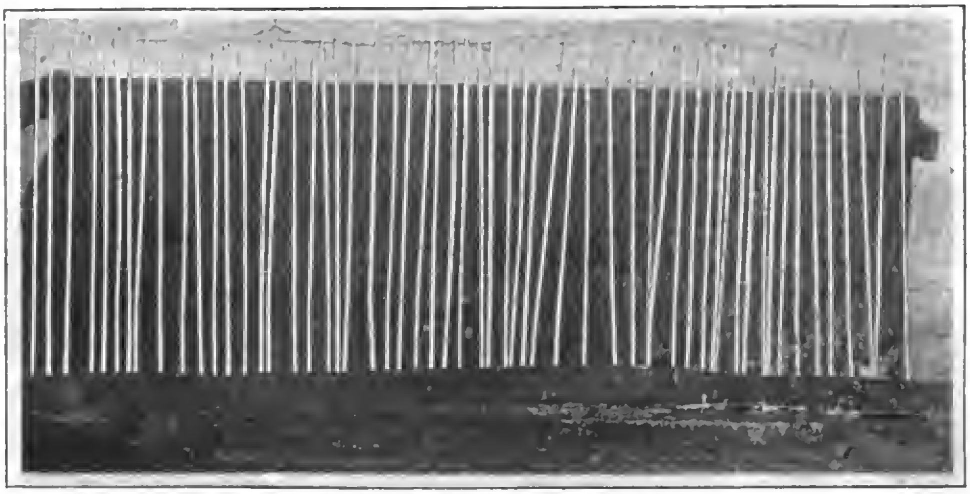

Fig. 5—Tubes, after they are cut to length, dipped in solder, and placed in a rack to drain and cool off before they are assembled

Very Little Power Wasted—From the point of view of the power required to drive the pump it is almost enough to say that the power consumption is but slight, yet even so, there are some who would prefer to have the proof, and with a view to showing definitely just what this power requirement adds to the pumping losses of a motor, the curve, Fig. 10, of a centrifugal pump as used on the Thomas "Vanderbilt Racer" is here offered, which test was made in the Thomas laboratory, at Buffalo, N. Y. This curve shows that the power required is not far from 0.2 horsepower when the pump is handling about 100 pounds of water per minute under the head then taken, and while the opportunity affords, it might be well to point out one or two other interesting matters as shown on the same chart.

Glancing at the curve marked "gallons per minute," it will be noticed that "impending delivery" begins at 680 revolutions per minute in this case. In other words, the actual quantity of water that a centrifugal pump will handle below this speed is not worth taking into account, and in gearing a pump of this character, it is necessary to run the pump at a speed somewhat higher than the crankshaft speed if it is true that the motor will do useful work at a relatively low speed. (Fig. 10, showing the curve mentioned and described will be shown in next issue.)

Contrary to the usual assumptions the power required is almost in proportion to the speed of the pump and the quantity of water is approximately on the same basis. Small pumps, as used on automobiles, do not conform to the laws of centrifugal pumps, even approximately, and it has also been found that altering the shape of the vanes has small effect on the result. If the vanes are curved it is almost a matter of no moment as to which way they rotate (with or against the curve), and it has also been found that, without any curvature at all, the results are very good.

It is fortunate that the performance of the pump is as shown, since the greatest requirement of water is when the motor speed is relatively low, and were the pump output to increase as the square of the speed the power required would increase in the same ratio approximately.

(To be continued.)

Some Solutions of the Private Garage Problem

By Morris A. Hall

Part 1

COINCIDENT with the purchase and delivery of the first automobile the new autoist comes face to face with the garage problem. Shall the new "pride of the family" be kept in a public garage or shall some roofed building be adapted or specially built for it? These questions as well as many others of a similar nature and correlative to them are of real, live interest to the new owner. Or, perchance, being a forehanded man, perhaps this problem has been the source of much time and thought previous to the purchase of the car.

At any rate, the problem exists and must be solved at once. Unless the owner be a wealthy man or an exceedingly careless one, it is doubtful if the public place will be satisfactory with its high charges for either live or dead storage and excessive overcharges for the slightest item out of the ordinary, to say nothing of the irritating delays in washing, repairing and other things. In not a few cases, outside of the largest cities, of course, the charges at the public caretaker's place would be beyond modest means and slender pocketbooks.

Of course, no wonderful profit attaches to the simple storage and washing of cars, but the charges for the latter service are not lowered any on account of the prospective profits.

Private Garage Best for Private Citizen—All of which soon leads one to the inevitable conclusion that when conditions, such as geographical location in a small town or the outskirts of a large one and other things which enter in, are right for building or the adaptation of an existing building, this method, resulting in a private garage for every citizen, is best.

Granting, then, the necessity for the private building to house the new car, and another question of equal weight and gravity pops up, requiring like the first immediate attention and a quick decision. This is, "Shall I adapt a barn, cottage, outhouse or part of the basement of my house for this purpose, or shall I build a special building exclusively for this purpose?"

To consider this briefly, suppose that an unused barn can be converted so as to serve the immediate purpose for the cost of a new floor, and the installation of water pipes for washing purposes, amounting to, say, $50. If a new garage house is figured to foot up $250 the former is very liable to be the choice. If, on the other hand, this is chosen, and not being fireproof, burns down and the car with it, not only is the expense of fitting up the barn wasted, but the cost of the car as well. Or, if the roof leaks and destroys the upholstering and paint so as to call for retrimming and repainting at a cost of $200, there was no saving in the made-over barn.

The use of a cottage in the rear or nearby, of a room in the basement or elsewhere, and other similar methods may be ranked with the foregoing as makeshifts which are liable to be very expensive in the long run, more so than the special house would have cost in the first instance. So, far from being a matter of waste of money, the special house represents an economy.

Special Building Offers the Greatest Advantages—Reviewing the above, it seems as if the cheapest way out is the construction of a small building for this specific purpose. In this there is a chance for every man to show his originality, and the building should be such as will reflect the personality of its owner in outward appearance, in internal arrangement, or in its appointments. The latter presents a subject to appeal to the ripest judgment, since into its puzzling decision enters the question of economy. The man says to himself, "Shall I spend all of the money for the house, and buy tools and supplies later on as I need them, or shall I economize on the house and start with a full set of tools, thus saving all repair charges from the start? Or, shall I take an intermediate position, spending on the house what I think should be spent on it, buying tools and equipment with what money is left and adding to this later on as the need for special tools or supplies becomes apparent.

If a man has natural ingenuity and the ability to do work with few tools, the latter is by far the best course and one that gives the most satisfaction in the long run. The writer knows of a man who equipped a garage like this, buying a tool each time a saving was made which could be directly interpreted in money values. That is, whenever he did something on the car himself which saved him work at a public repair shop costing, say, $2, he invested the money in a tool or tools amounting to this or less. In this way he accumulated a fine set of needful tools, and as he looks upon it, absolutely without cost to him.

This tool subject is one that must be given attention very early in the matter of a private garage, since, when the total amount to be invested is limited, any source of expenditure must be considered. As tools not only represent an expenditure, but if care is not used, a very large one, this matter should be the subject of much thought. Correlative with it and requiring solution equally early, is the matter of what portion of the total repairs the new owner will make himself. If he decides that he will make all of them and be independent of the repair shop, he will need more tools than will the man who decides to make only the simpler repairs.

Tools Which the Maker Furnishes, Usually—Bearing indirectly upon this, the tools which come with the car influence the result. The following is an extract from the catalogue of a high-grade maker:

A full supply of drop-forged and hardened tools, with tool bag, is furnished with each car, as follows: Jack, six engineer's wrenches, two monkey wrenches, four socket wrenches, two spanner wrenches, hub cap wrench, pet cock wrench, combination pliers, screwdriver, valve spring tool, cold chisel, ball pein hammer, oil can, tire pump, tire tools, and tire repair kit.

Other makers furnish, in addition to the above tools, water pail, hub puller and wheel puller. This equipment will, of course, vary with different makes of cars and the price of the same, the higher priced cars furnishing more tools than do the makers of lower priced machines. In general, the above may be assumed to be a fair outfit as furnished with a $3,000 car.

Proceeding on the assumption that the above tools come with the car, it will be wise to sketch out about what extra tools the beginner will need. In case tools to this number and variety are not given free with the car, the assumption is that the owner will attempt to secure them within a reasonable length of time. Having these tools, then, it would be advisable to provide in addition, a stillson wrench of about 10 inches length open, which will take any size from 1-8 inch up to 1 inch, this being about as large a diameter as will be met with in gasoline-engine piping or tubing. The screwdriver supplied with the car will doubtless be all right, but a use will soon be found for other and different sizes, as this one will be a sort of general utility size. It is therefore advisable to purchase two additional at once and others later as the need arises. The two purchased should differ in that a small one with a wood handle will be needed for ignition purposes, one having a blade 2 inches long by 1-4 inch diameter being plenty large enough. For the other, a very long, moderate size comes in very nicely for inaccessible screws. A good size for this would be 10-inch by 3-8-inch blade.

Someone has said that it is possible to drive an automobile across the United States with no other repair parts than a bundle of wire. In the late Glidden Tour, three of the contestants carried no spare parts, only a roll of wire. In view of this, it is advisable to purchase a pair of wire-cutters. These come in several varieties, one being selected to suit the individual. Thus, nippers are for that purpose only, while side-cutting pliers may be useful in other ways. The price favors the latter, too.

Always Use a Soft-Headed Hammer on Threaded Shaft Ends—In assembling or dissembling, it is often, in fact, usually, necessary to pound or hammer on the end of a shaft or other part which is threaded at that point—that is, has threads right up to the end upon which the hammer is used. For cases of this sort it is not only advisable, but necessary, to have a soft-headed hammer. The heads can be bought separately either of copper or lead, the latter being both cheaper and more serviceable. They are cast with a narrow slot through the center, into which an ordinary hammer handle can be fitted in a few moment's time.

In case an ordinary hammer is used on a shaft end or other part and burrs up the threads or otherwise marks the finished piece, it will be necessary to use a file to take off the marks or protruding parts before the whole can be assembled. This calls for a file, which is not included in the tool kit. So, it will be well to buy a few files. These, too, will differ according to the nature of the work they are to do. Thus, for filing or, more correctly, dressing up, trembler points on coils, or sparking points on spark plugs and similar small, delicate parts requiring careful treatment, a very small, delicate file of the highest grade is an absolute necessity. Such a size is Nicholson's X F Swiss No. 6. In addition, a round file and one large flat shape is needed. For the former a 6-inch smooth cut will do, while the other should be a smooth, double cut of about 8-inch size. Others will be added later on, but these will do very nicely for a start and cost little as compared with their usefulness. Money saved on files is a poor economy, since they never reach the end of their usefulness. A poor file is an abomination in the sight of a real mechanic anyway. So, pay the price asked for the best when you buy files.

Since to the beginner the whole ignition system is mysterious, it is a good plan to get a reliable check on the amount of current being furnished, which may be done by the use of a voltmeter and ammeter or a combination of the two in the form of a voltammeter. For this purpose an excellent instrument is one that reads from zero up to 14 volts and zero to 30 amperes, but this wide range is not wholly necessary and costs money. The beginner may get a perfectly serviceable instrument of narrower range for less money. This is used for checking up ignition cells, but as pointed out in a recent article in The Automobile, may be used to check up wasteful coils as well. It is a great help in time of ignition trouble, when the action of the two meters denotes some specific trouble, enabling the operator of the car to go right to that point, whereas another driver without it, would have to hunt for hours to even find the trouble.

Necessary to Have Some Shop Equipment, Too—If a man is to do all of his own repairing he will need a few shop tools—that is, he will have to equip his garage as a small shop. One of the most necessary things is a vise for holding a piece while work is being done upon it. This will, of course, need a work bench as a fixed support, but as that will be considered a part of the garage, under the heading of building and equipping the structure, it will here be taken for granted. In size it should be large; since an owner never buys but one, it is advisable to have it large enough to handle any work. If large, small work can be held in it equally well, while if small, there will always be some large piece to be worked upon, too large, in fact, to go within the jaws. A vise which opens to 3 1-2 inches will take any part of the automobile barring the piston, crankcase halves and gear case halves, which two latter are seldom put in a vise, so that they may be neglected. If it is desired to have a vise large enough to take the piston it will have to be one that opens 6 inches, for while very few engines have that diameter of piston, it should never be put in the vise and clamped up without copper-facing strips, which will receive the imprint of the roughened jaws instead of the machined surface of the piston.

This larger size will double the expense at least. Bearing the same relation to large stock (whether round, square or of some other shape) as do the nippers to small wire, is the hack-

An Old Barn Sometimes Makes an Excellent Garage Without Much Alteration saw. This will be found very useful in many ways, and it is advisable to have one. The frame need not cost very much, but the working part of it, the blades, should be of the best. A cleanly man would purchase separate and suitable cans for oil, waste and gasoline, but this is not wholly necessary if economy be the order of the day. In purchasing oil and gasoline by the barrel wooden barrels are obtained (the ones in which they come) and the liquids may be kept in them and only drawn off as occasion demands. This is an excellent plan, since they are both cheaper by the quantity and the reservoir cost is saved. This plan has the disadvantage in that the fire risk is still present with the wooden barrels, whereas this is not so with fire-proof sheet-metal cans for that specific purpose.

All gasoline should be strained before using, since the quality of fuel grows steadily worse each year, so much so that to-day it presents a very large and serious problem. By straining all

City People Are at a Big Disadvantage in Building Garages

that is put into the machine the amateur owner is doing all that lies within his power to do, since beyond that chemical changes are necessary to purify it further. A funnel with a gauze insert is good, and better, although slower, is chamois.

In building and equipping the place, the owner will provide lifting and shifting means for heavy and bulky weights, to be described more in detail later on, so that for the present the jack furnished with the car will suffice. Beyond this the other tools furnished and those suggested above, the man of limited means would need little else at the start. After some use every man doing all of his own repairing will need more complicated and more expensive tools of various natures.

For instance, one of the very first things to buy would be a vulcanizer, since tire troubles are many and various, and the charges at the public garage or repair shop are equally many and various. Not only can much money be saved on immediate repairs, but it is thus possible to give the tires more intelligent care at all times, resulting in greater mileage per tire and lessening the per-mile cost of running. This necessity is more than apparent from an inspection of the following table of tire troubles, which has been carefully compiled from thousands of experiences with repairs by one of the large tire companies:

CAUSES OF TIRE TROUBLES

SHOES

17.3	per cent in consequence of insufficient inflation.
3.5	per cent in consequence of rusty and dented rims.
1.5	per cent in consequence of cutting off of cover pad through inadequate fastening of butterfly screw, whereby the cover could shift on the rim.
1.8	per cent in consequence of sudden braking, which scoured through tire at one place.
.2	per cent in consequence of contact with oil or other fatty substances, which are known to decompose rubber.
29.4	per cent in consequence of perforation by nails, stones and pieces of iron.
4.3	per cent in consequence of light damages and cuts on the threads, easily repaired.
4.9	per cent in consequence of considerable outer damages, whereby the upper canvas layers were destroyed.
37.1	per cent in consequence of normal wear and tear.
100	

TUBES

13.0	per cent nipped in mounting.
7.2	per cent places scoured through in consequence of defective mounting or the presence of sand and small stones in tire.
9.5	per cent through defective mounting.
6.8	per cent through riding on deflated tubes.
5.8	per cent damages through defective and wrong cover holders.
10.0	per cent valve defects through wrong manipulation of valve.
43.7	per cent normal wear and tear.
100	

From this it is immediately apparent that the driver of the car is responsible for much of tire trouble. This part of it is the one which might be helped by owning a vulcanizer, so that the little things, such as the "4.3 per cent. in consequence of light damages and cuts on the threads, easily repaired," mentioned above. This is an expensive outfit, however, and one that it would be inadvisable to buy at first, when there was a possible doubt as to the owner's ability to make his own repairs.

The same remarks apply to such items as taps and dies, which anyone can manipulate, but for which there would be no immediate necessity; in fact, there should be no use for them for many months of running. As a whole set, comprising about twelve of each, is rather high in price, the better plan is to wait until their use is a necessity and then buy them.

Some Idea of What the Whole Bunch of Tools Cost— Without going into the details of the various tools and things mentioned above, which, as explained before, are but a few of the total that one would like to have, and the least expensive, at that, it may be said that those described above should not cost in excess of $20. This, however, is exclusive of the taps and dies, vulcanizer, cans of oil, waste and gasoline, but includes the voltammeter. Inclusive of these the total would be triple and from that upward, according to size and quality. Further on a number of special tools and ways of doing one's own work will be elaborated on, while special apparatus will be illustrated.

Having settled, then, upon the number and cost of the tool equipment, the amount to be spent determines to some extent the size of the house, as well as the construction. But, generally speaking, there are eight forms of construction possible. These are:

1. Wood,
2. Wood and steel in combination,
3. Steel alone,
4. Concrete,
5. Hollow tile,
6. Other forms of fireproof construction,
7. Concrete in combination with any or all of the others.
8. Brick or stone.

There are other forms of construction and some other methods of doing the work which really influence the situation, but which do not deserve to be classified as a separate form of construction. Thus, as a simple example of this, concrete may be made up into bricks or stones and then laid up one at a time, as bricks or stones would be, or it may be made all at once, moulds being constructed for the entire sidewalls, which are then poured

One of the first things which the builder will want to know is the cost. This cannot be given except in a broad way, as conditions vary so much.

(To be continued.)

CAUSES OF TIRE DEPRECIATION AND ACCIDENTS

ENTIRELY beside the question of the sizes and quality of tires, or the matter of inflation, there are material reasons why their life may be materially shortened, among which the following are prominent: If, for any cause, the axles sag, the load will come on the tires in such a way as to deflect them out of the plane of the wheels and rim-cutting will follow. Fig. 1 shows a prolific cause of axle sagging, due to the use of rather small stays for the axle and saddles of no great competence. If the stay jumps out of the saddle, the load will then fall on the unstayed tubing, and if it is so frail as to require the use of a stay, it will sag when the supporting pressure is withdrawn. When this class of trouble is found in a car, it will be best to put a preventer clamp on the stay, just at the saddle, thus holding the stay into the saddle; stays should be under quite some tension.

Parallelism Must Be Maintained—There is still another class of trouble, due to the lack of parallelism of the road wheels. It may be one or both of the front wheels that will be found out of line, and with a length of stout cord it will be possible to ascertain just which and how much. The front wheels

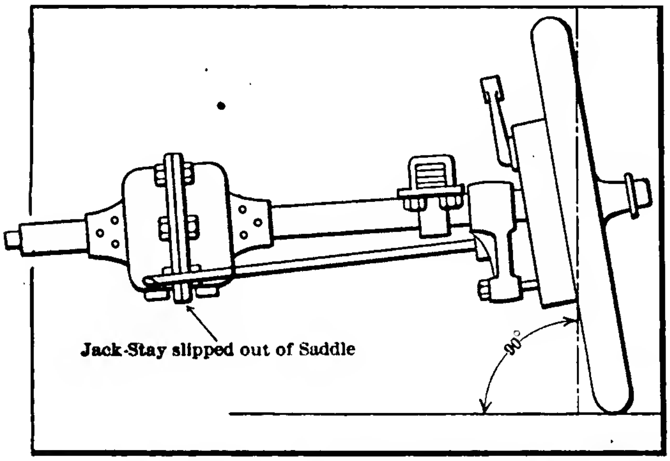

Fig. 1—Slack stay out of saddle, showing how axle sags in consequence

should be either parallel or they should toe in just a little bit. True, if they toe in they will cause wear on the tread of the tires, but it is better to have a suspicion of this trouble than to have them toe out. If the front wheels do toe out, steering will be attended by some additional difficulty, but if the toeing is slightly in, steering will be easier than when the wheels are exactly parallel.

If the wheels are parallel, a length of cord, when it is passed along from back to front, will just contact with the tire if the front and rear tires are the same size and equally inflated. If they are not the same diameter, the same idea may be used, but a rule, measuring from the felloes, will enable the workman to determine any difference existing. A long straight-edge, made of wood, will do this work very nicely, but there will be no difference in the principle, and in view of the clearness of the figure it is not believed that further explanation will be necessary.

Some Noise Emanates from Mud Guards—This year's automobiles are to be noted for silent performance if indications count, and makers of cars are paying much attention to valve and gear noises. In the meantime, since, in many cases, body work is done outside, with which mud guards are included, it will be well to remember that some of the former practices in connection with body work were not noted for noiseless performance. If stove bolts are used to fasten mud guards into place, it is highly improbable that the fastenings so made will prove to be secure, and just so soon as the nuts back off, as they invariably do, noise will creep in only to destroy the otherwise excellent performance of the cars.

Fig. 3 shows a class of construction which is rather common, and, unfortunately, it is extremely difficult to fasten the flap of the mud guard since it passes down between the rear wheel

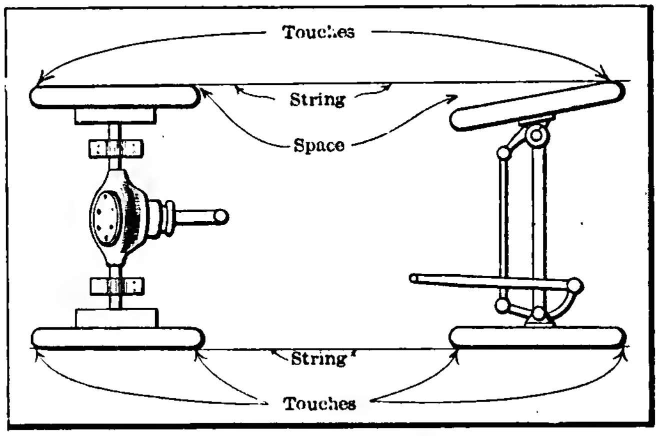

Fig. 2—Depicting one front wheel toeing out and method of lining up

and the rear spring suspension just at a point where there is nothing to tie up to. In any case, in view of experiences, it is necessary to do something about it, and if there is nothing to fasten to it is desirable to so fashion the "irons" that they will support the guards, and that better work on mud guards will bring its own reward is one of the points to be made.

Springs Should Be Tightly Clamped—While the subject is up, attention will be called to the most likely cause of spring failure. If the springs are not tightly clamped to the perches, they will fail in service, even if there is evidence of good designing, ample metal used, and a display of good judgment. By clamping the springs tightly they are prevented from deforming at the perch, which local deformation invariably ends failure; what is wanted is uniform bending over the whole length.

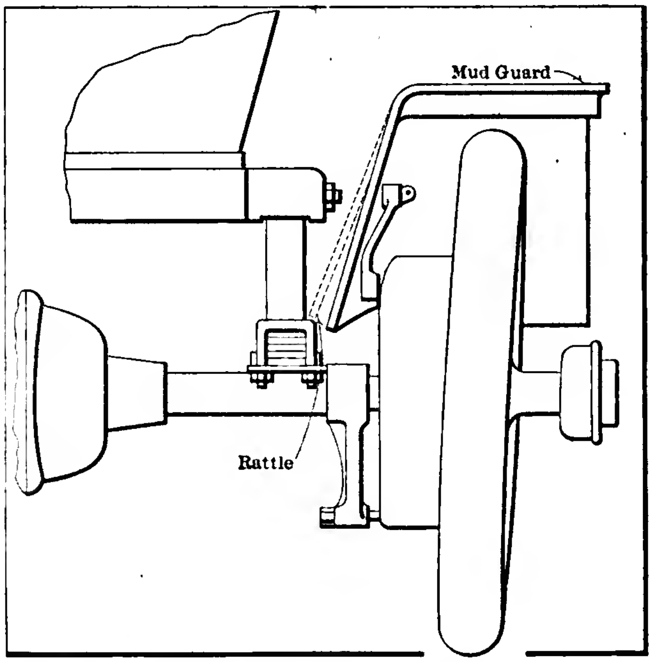

Fig. 3—Vibration causes the free end of the flap to interfere and noise is inevitable

HARD TO START "HER"

Editor THE AUTOMOBILE:

[2,059]—Will you kindly advise me through "Letters Interesting, Answered and Discussed," how to eliminate trouble in starting my 1907 four-cylinder car in the morning. It is a * * * * * * car with their own make of carbureter. I have to crank "her" over and over for about five minutes before getting the engine to start, and after so doing "she" runs all right. Aside from the matter of difficult starting, I have no fault to find. W. H. AHRENS.

City Island, N. Y.

It might be said that there are three sources of trouble of this sort, that is, on a cold morning. These are: carbureter not properly adjusted; ignition "out of kilter"; and natural inability of gasoline to vaporize in very cold weather without supplying heat to it from an external source. The first and second may be fixed and that, too, comparatively easily, but the third cannot be changed as long as gasoline is utilized as a fuel.

As for the first, carbureter out of adjustment, there are two things to consider. Does the carbureter give sufficient fuel for starting purposes, and is the air supply reduced to a minimum for this same purpose, both being irrespective of the amount supplied upon other occasions? You should know that for starting easy, the fuel should stand in a small puddle, so that the small amount of suction created as the pistons are pulled down at the slow speeds possible with manual rotation will be sufficient to pick up a lot of fuel, forming a combustible gas. If the fuel does stand in such a puddle; that is, if there is an excess of fuel at starting time, look into the matter of air supply. For starting purposes a very small amount of additional air is needed; in fact, practically none. So, to start the engine successfully, the auxiliary air supply should be shut off entirely and the main air supply reduced to a minimum. This will result in the overrich mixture necessary being sucked up into the cylinders.

If the air be allowed to enter as in ordinary running conditions, this additional amount of air will serve to render the mixture thin and weak, so that the feeble spark obtained at the speed of rotation will not be sufficient to ignite it. The ordinary magneto gives a spark of strength or igniting qualities in proportion to the speed of rotation of the armature, the ordinary speed under working conditions being somewhere between 400 and 2,000 revolutions per minute. The best possible speed of rotation by hand is not over 45 to 50 revolutions, so that the armature rotates very slowly. Consequently, it generates a weak spark. It is then apparent that the spark not being all that it should be for instantaneous and perfect combustion, the mixture must be just about exact in order to have an explosion. If you have no explosion, the engine does not start.

Just as a suggestion, try the effect upon the starting qualities of lowering the level of the gasoline nozzle within the carbureter. Open the carbureter and screw the nozzle down about one full turn. The effect of this will be to raise the level of the gasoline correspondingly. The fuel will then feed to the engine more readily, and you will doubtless find starting easier. You will also have to look out for flooding at other times, as the change in the fuel level tends to feed more fuel at all times. Doubtless you will have to change the level several times to get the best result.

This question has been discussed in the columns of THE AUTOMOBILE several times before, and several of the discussions were illustrated. In referring to these discussions, you may find the illustrations helpful in understanding the trouble and its remedy. You will find the subject of the effect of altering the fuel level discussed in the May 13 issue in answer to letter 1,876; June 17, letter 1,910; July 15, letter 1,940; July 22, letter 1,592; "How to Fix Carbureter," page 485, September 16 issue; "Engine Hard to Start," page 522, September 23 issue. The illustration is in the June 17 issue.

USE OF CLINCHER LUGS

Editor THE AUTOMOBILE:

[2,060]—Being much interested in and deriving much benefit from the discussion of current topics in the columns of "Letters Interesting, Answered and Discussed," I would like to ask what real use are the lugs or retaining bolts where clincher tires are used? I have a model F * * * * * * equipped with clincher tires and lugs. I have removed the lugs, plugged the holes in the rims, and find no bad effect therefrom. The tires can not creep under any condition if inflated, so I see no use for the lugs, except to pinch the inner tubes and make about nine-tenths of the trouble when you apply or remove a tire. I would like to know wherein it is unsafe or unwise to eliminate them.

Rodman, N. Y. H. F. RICE.

If there was no use for these and they were as superfluous as you would like to make it appear, the tire companies would not put them on, for they cost money and so does their application. No company would voluntarily put out something which cost real money and was actually useless. It seems that the whole argument lies within your statement "The tires cannot creep under any condition *if inflated* * * *"

The italics are ours, used to bring out the point that the tires are not always properly inflated, so that the holding power, whatever it may be with a fully inflated tire, is not always perfect, and it is advisable to have the lugs for protection in the unusual cases. More than this, these tires do come off when well inflated, as was proven last Fall when a picture of a racing car throwing a tire of this kind was given wide publicity. The tire then was fully inflated, so that the pressure could not have worked in that case. If not in that, why in others?

HILL CLIMBING STUNT

Editor THE AUTOMOBILE:

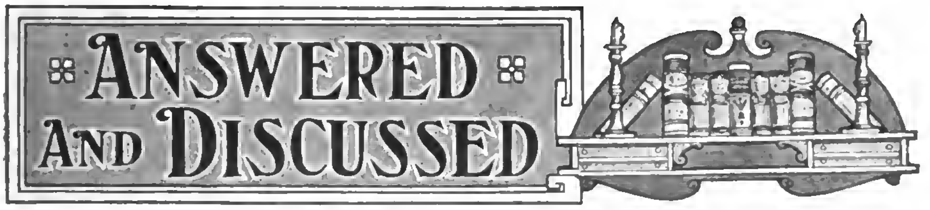
[2,061]—Will you please inform me if it is injurious to my motor (45 horsepower) when climbing a hill on the high gear, and the motor lags a little, just at the top, to slip the clutch a little. The latter is of the multiple disc variety. In "Motor Age" a couple of weeks ago, it stated that this was a trick which every expert driver knew and practiced. I have tried it several times and found that the motor will pick up immediately, and the car finish the hill without slightest difficulty. Of course, this is only if one is just at the top, as otherwise I should think the proper thing would be to change to a lower speed at once. But I was told last week that it is very bad for my motor to slip the clutch as I have said. As it was advocated in an automobile magazine, I will be greatly obliged if you will let me know your opinion.

Babylon, L. I. A SUBSCRIBER.

No reason appears why this practice in the hands of a skillful driver should injure the motor. The idea of the people who advised you to the contrary was doubtless founded upon the following supposition: The motor, when laboring very hard, that is, working, not laboring in the sense of pounding, if the clutch were suddenly thrown out, would speed up to a very high speed, the load under which it had been working so hard having been removed. Then, having attained a high speed, running free of a load, the same very heavy load is thrown back on it, tending to check it as suddenly as it was freed. It might be thought injurious to free the motor so suddenly and let it run so very fast. Also, it might be thought injurious to throw the load on very suddenly after it had attained speed. Both of these contentions, however true they might appear, fall flat when the amendment is made that the process be controlled by a driver of experience, who certainly never would take out the clutch suddenly or drop it in suddenly in a case of this sort.

The process of resting the motor near the top of a steep hill when ascending on the high gear, then should be practised only by an experienced driver, who will know how to release the clutch gently and let it back in after a very small interval of time not over a part of a minute, without a jerk, but slowly and gradually, so as to get the whole advantage of the increased speed of the motor, rather than drop it back in so as to be a dampening effort on the speed.

As you say in the last part of your letter, it should be used only at the very crest of a hill, and should not be resorted to as an excuse not to change gears, when the latter was really necessary. Anywhere below 40 or 50 feet from the top of the hill, the driver should drop down into a lower gear, and not overload the engine.



MATERIAL FOR GEARS

Editor THE AUTOMOBILE:

[2,062]—I have a four-cylinder car of well-known make, which runs very well, with the exception that the timing gears are very noisy and clatter all of the time. In the early Summer the car was fitted with new gears as follows: Main shaft, bronze; cam gear, steel; idler, fiber; pump and magneto (one gear) bronze. These ran very well, and made no noise, until about a month ago, when the fiber gear swelled and then stripped. The engine was then fitted up with new gears all around thus: Main shaft, bronze; camshaft, steel; idler, steel; pump and magneto, bronze.

Within a very short time, these gears, which by the way did not fit perfectly when new, as there seemed to be considerable play between all of the gears, became very noisy, although they had been well oiled. Now, the noise seems to be getting worse.

Now I would like your opinion of the best gears to put in when I replace these, and what the general practice is among the oldest builders of cars. Which combination of gears will run the longest, and which will run with the least noise; all gears of steel; steel and bronze; or a steel or bronze combination with fiber? In other words, of what material would you make each gear of to have the most silent and durable timing gears. The main gear works the idler, and the idler, the cam gear and the pump-magneto gear. Has the fiber gear been perfected so that it is perfectly safe?

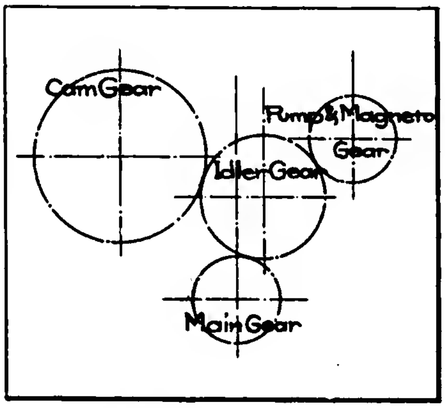
Port Jervis, N. Y. F. T.

Judging from the arrangement of the gears, as shown in the sketch, it would seem as if some noise-preventing gear for the idler would serve well. The other gears could then be of any desired material, as the material should have no influence upon the noise. The mistake that was made, from the point of view of silence, was in replacing the fiber gear with a steel gear. This was the only change of material, and it was a fatal one from your point of view, as it produced just what you wished to prevent. A number of makers use rawhide as well as fiber. Either one of these has much to commend it, but you should not expect too much strength and too good wearing qualities from this kind of material. You should be content to have a quiet engine, even if you replace a gear now and then.

Just as a pump shaft is often arranged with a cotter pin, which shears off in time of trouble, saving the expensive pump, so your gears might include one which would wear out quicker than the others, but while there and working would render the whole set of gears quiet. Give the fiher gear another trial.

Many of the oldest makers are now turning to the specially-cut gears for quiet action. Thus, one of the oldest uses a herringbone face made up of a pair of helical gears set side hy side, but with the helices pointing in opposite directions. This is an unusually quiet form, as is also the spiral gear, the worm gear, and other forms. To have a set of these specially cut for your car would be somewhat expensive, but would be quiet and durable as well.

Since you do not go into detail about the gears themselves, we cannot say exactly, but your statement about the play between the gears sounds funny. There is intended to be play between adjacent gears, and if you thought that they should fit up tight, you were mistaken. In cutting, the gears are so made as to have a small amount of play to and from one another. It may be that you mean that they were set too far apart, and that this clearance was materially increased so as to be very noticeable. If this was so, you were right, and the gears did not fit perfectly.



Arrangement of F. T.'s Gears

Fiber gears are now so well made as to give satisfactory service when properly used and the manufacturer's directions followed. For one thing, rawhide gears do not run well in oil, and the makers advise against its use when using that form. Makers of fiber gears may also advise against its use.

WIDELY VARYING TREADS

Editor THE AUTOMOBILE:

[2,063]—Why is it that some manufacturers make cars with 55, some with 56, some with 56 1-2, and still others with 60-inch treads? What is the reason for this variation? J. H. TYLER.

Buffalo, N. Y.

Standard railroad tread is 4 feet 8 1-2 inches, that is, 56 1-2 inches. The existing differences represent the result of neglecting the odd half inch, or of a misunderstanding of the exact figure. The extreme difference as shown by the 60-inch figure represents the cars built for Southern roads, where the wide tread is in favor, and replaces the ordinary railroad gauge used elsewhere. Cars built especially for Southern roads have that tread.

PROPER VALVE SETTING

Editor THE AUTOMOBILE:

[2,064]—I have a four-cylinder runabout, four-cycle, size 3⅝ bore, 3½ stroke, which has got out of square, I presume through wear and lost motion in the valve operating mechanism. That is, "she" does not beat square in the exhaust, as we say in speaking of a locomotive.

Valves are placed opposite each other in the head. The cams are made solid on cam shafts, and valves are operated by long rocker arms that have a screw adjustment on the end next valve stem, as shown in the enclosed cut.

Will you please inform me how to adjust valve opening relative to position of piston stroke to get best results as to power and speed?

Don't give any algebraic formulae; just state in plain fractions of an inch how far off dead centers inlet and exhaust valves should begin to open.

North Adams, Mass. NOVICE.

Not knowing the length of the connecting rod of the engine in question, we cannot give you the distance you wish exactly. Similarly, the cams were constructed for some certain valve setting, and should we give you a different one, the engine would not run well. You should write to the manufacturers of your car and ask them what valve setting they intended the engine to have. Knowing that, we could compute or lay out the exact distance the piston would be from each end when the various valve actions commenced or ceased. As it is, what we can give you will be approximate, and, as said before, the engine may not run well with this setting.

Set your inlet valve so as to start to open when the piston is 3-64 inch below upper dead center, that is, when it has turned so far that the piston has gone down that amount. Similarly, for the exhaust valve set that so as to commence to open when the piston lacks from 5-32 to 3-16 inch of reaching the lower center, that is, that much before the lower center is reached. If you cannot measure into 64ths, 3-16 inch will be close enough for you to find out if the inlet setting recommended is right enough to use with your engine.

The settings given above correspond as nearly as we can lay it out (guessing at the length of the connecting rod) to a lag of the inlet valve amounting to 10 degrees on the crank circle. The exhaust setting corresponds to a setting of 30 degrees before the lower center.

Current practice in valve settings varies from one factory to another, and you may find that with your cams, the inlet opening as given makes the inlet closing come too late. So, too, with the exhaust opening, you may find that your cams in combination with this setting, make the exhaust closing come too early.

Any angle of inlet opening less than the one given (10 deg.) would decrease the distance given, and any greater angle would increase it. With the exhaust, a smaller angle would lessen the distance given, while a larger one would increase it. We state this because you may set according to the above figures first, and write to the manufacturers later. In that case, you would have a means of comparison.

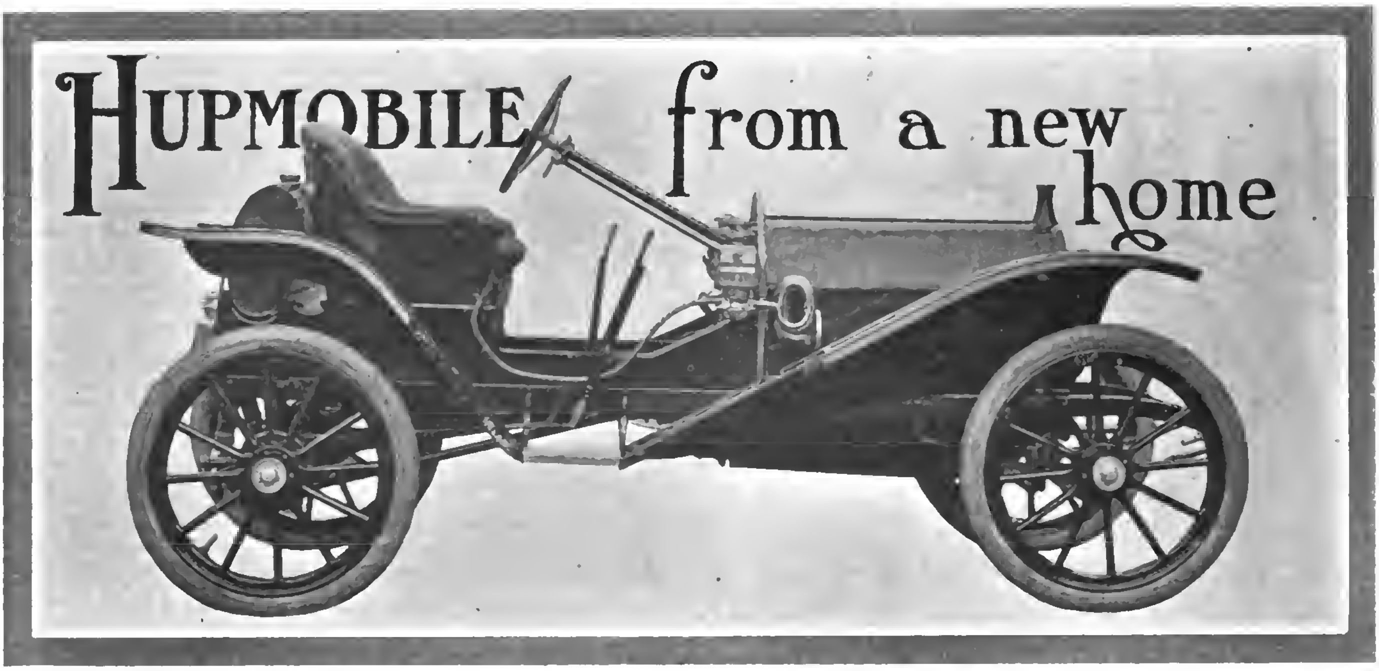


Fig. 1—Car as seen from the right side, showing a low seat, much tilted wheel, and fuel tank to the rear

LAST YEAR the number of cars produced of this make reached the comfortable figure of 500 despite the lack of facilities such as are now at the disposal of the company. The new plant, with a floor space approximating 50,000 square feet of concrete block construction, is a model of its kind, and Model B, which is the car for 1910, is being turned out under the most favorable conditions at the rate of thirty a day. The title illustration is a fair view of the car, presenting the earmarks of elegance, utility and evidences of a certain sturdiness which is borne out by performance in service.

The general design is such that the appearance is that of a racing machine, and since this is direct evidence of a low center of gravity and all that it implies, it will come as no surprise to learn that the road performance is praiseworthy in the extreme. With the seat located at about the point of least motion of the body and low, the sensation of ease and comfort is experienced, which is accentuated by the well-regulated distance from the front of the seat to the dash.

Four-Cylinder Motor Is a Feature—With a bore of 3 3-4 and stroke of 3 3-8 inches, the four-cylinder motor used is rated at 20 horsepower, and considering the light weight of the complete car, mode of suspension and other favorable considerations, the power situation lends confidence. The power plant is self-contained, and suspended in such a way that the chassis frame deformations, due to road inequalities, are not transmitted to the machinery.

The flywheel, 14 inches in diameter, weighs 40 pounds, is provided with helical blades to propel air to the radiator and is placed in front. The starting crank is journaled in a cast extension which is fastened to the front cross member of the chassis frame and is held out of engagement by a helical spring. The crankshaft, of special (heat-treated) steel, is designed to afford great initial rigidity, and the connecting rods, of H-section steel (drop forged) engage the crankshaft through bearings of Parsons' white bronze of liberal projected area, thus assuring long service in the absence of bearing trouble.

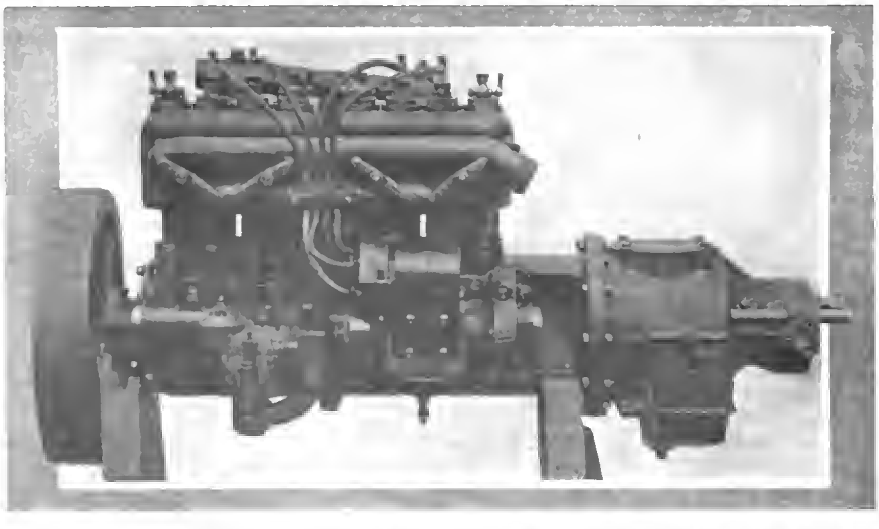

Fig. 2—Left side of the motor, showing magneto, fan in the flywheel, sliding gear system, Breeze carbureter, and unit construction

The pistons, of a special grade of cast gray iron, are taper ground, 3 5-8 inches long, with an oil groove 7-8 inches wide to oil the wrist pin, and three eccentric, bevel, split, packing rings prevent the leakage of compression. The rings are machined to near size and ground on three faces. The valves are 1 1-2 inches in diameter, made of nickel steel and finished with a 45-degree seat. All valves are located on the left side of the motor and spark plugs are located over the inlet valves.

Camshaft Placed for Quick Inspection—Referring to Fig. 4 of the camshaft, it is provided with five bearings in a separate demountable member of the crank case and the removal of ten nuts allows of removing the member, including the camshaft, gear and tappets. The shaft of the type with integral cams is babbitted in, which is a new idea in automobile work, and the gear, of the silent type, is exposed to view and may be gotten at. The magneto is bolted to a shelf which extends out from the same member and the same scheme of bolting renders it feasible to demount the magneto and its driving mechanism without disturbing any other part of the motor. The half-time pinion on the crankshaft is of steel and the thickness of the gasket between the cover and the case may be varied to alter adjustment of the meshing gears.

Bosch Magneto Provided for Ignition Work—The Bosch magneto is of the high-tension type with fixed ignition, and the wiring system, which is neatly and securely installed, comprises five leads, four lead to the respective spark plugs and the remaining lead connects with a switch on the dash; the switch short-circuits the magneto for purposes of cutting out the ignition.

Oiling System Has Special Features—As Fig. 3 shows, the oiler is placed on the exhaust side of the motor and the heat of the exhaust keeps the oil at a constant viscosity. The oil is piped to the crankcase by visible piping and the system of oiling is by splash. Oil pockets are provided over all bearings and the lubricant, when it splashes, falls into the pockets and runs down through proper channels to the respective bearings. The rate of flow of the lubricating oil is controlled by a suitable adjustable valve, easy of access, and by means of a lever system the flow of the oil is increased with the speed of the motor.

Multiple Disc Clutch and Sliding Gear—From Figs. 2 and 3 of the extension of the crankcase for the transmission gear, including the clutch, to Fig. 4 of the same members separated, leads to a better understanding of the nice details inclosed. The multiple disc clutch is of liberal proportions, having nine discs, designed for easy but positive engagement and the two-speed (and reverse) sliding gear is something of an innovation in automobile work. The low speed is designed with a gear ratio of 2.7:1 and the high speed is "direct."

The control is with a suitably contrived side lever of artistic appearance and the system is "selective." The gears are of 20 carbon steel, bone-hardened and drawn in oil after machining and accurately generating the gears, which are ten pitch.

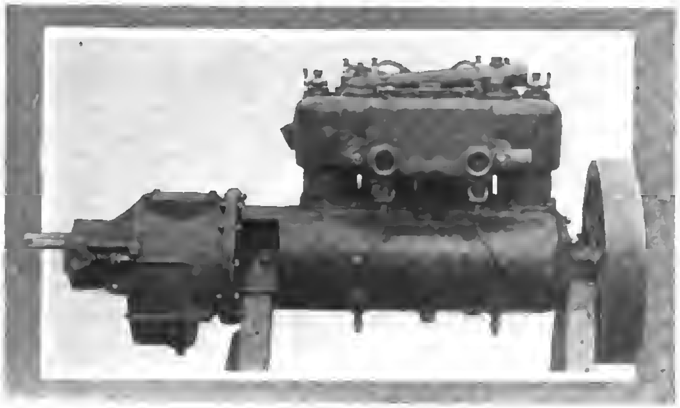

Fig. 3—Right side of the motor, showing flywheel in front, and lubricating oil tank which is warmed by exhaust heat

The faces of gears are 5-8 and 11-16 inches, respectively, and layshaft gears are riveted to a bronze hub that journals on a hardened and ground shaft.

Front Axle Represents a New Departure—In the latest car the front axle is of the I-section, drop forged from 40 carbon steel, and the yokes are forged integral. This is considered a big advance over the former practice on Model A, which was a built-up tubular type. In the new axle one of the noteworthy points is in the use of large steering arms, 13-16 inches in diameter, mounted with adjustable ball bearings of large diameter.

Some Prominent Chassis Features—The rear spring suspension is one of the most prominent features, and in view of its fine performance in the last year's cars, it is continued in Model B with a good showing of confidence. This spring is designated as an inverted double sweep type, has a ball socket clipped in the middle, taking a ball-ended taper shank bolt that seats in a bracket in the middle of the rear cross member of the frame, giving the frame a three-point suspension.

The eyes of the spring are pivoted to sliding journals having a bearing on a cross-bar parallel with and to the rear of the axle, and arms extend out from the brake supports to support the mechanism. This construction allows of suspending the chassis frame considerably lower than usual, and the fine appearance of the car is almost wholly due to this method of spring suspension, including semielliptic front springs.

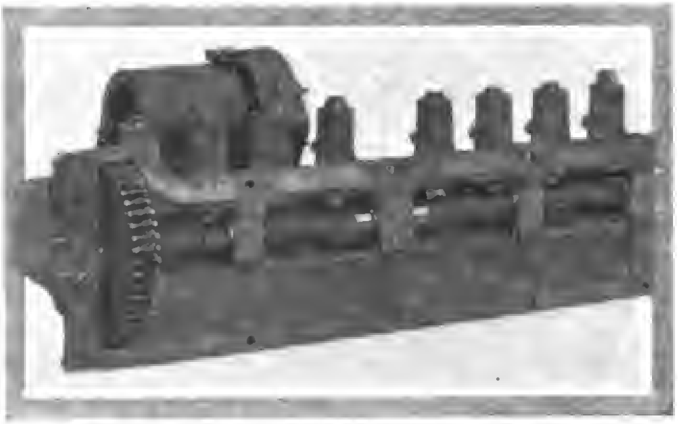

Fig. 4—Camshaft, indicating how it is placed in a separable part of the case and can be removed, with its gear, at will

There are four internal expanding brakes, faced with asbestos fabric, which is rendered strong by interwoven copper wire. This double set of brakes, with two sets of shoes in each wheel drum (side by side) being cam actuated, considering a straight-line system of linkages and rods, assures a safe and permanent braking system. The brakes are manipulated by side lever and foot pedal, respectively.

Steering Gear Is Nicely Worked Out—The steering gear is of the inclosed rack-and-pinion type, both members bone-hardened and ground accurately to size, and sustained straight-line connections assure entire freedom from bending moments. The housing of the gear is riveted to the front cross member and holds a liberal bearing for the shaft, which is inclosed and tilts back at a convenient angle from the point of view of appearance and utility. The steering wheel is of standard diameter, has a spider of aluminum and the spark and throttle system is above the wheel.

Additional Important Considerations—The wheelbase is 86 inches with a standard tread, and 30x3-inch G & J tires are used. The road clearance at the lowest point is 11 inches and 13 inches clearance under the flywheel assures safety. The color of the body is "Hupmobile Red" with black moulding and hair striping. The upholstering is of a substantial character with plain black machine buffed leather, padded to support the back without interfering with easy motion of the shoulders.

The oval gasoline, placed at the rear of the seat, is a 1910 innovation which adds materially to the general appearance of the car, and it has the further advantage of rendering the fuel system easy of access. The tank has a capacity of 11 gallons and is high enough up to allow of a gravity feed. The whole car weighs 1,100 pounds, and it is claimed by the makers that it will reach a speed of 50 miles per hour. The price, including oil lamps, tools, with full equipment for the road (with magneto) is $750, a reasonable figure for the average buyer.

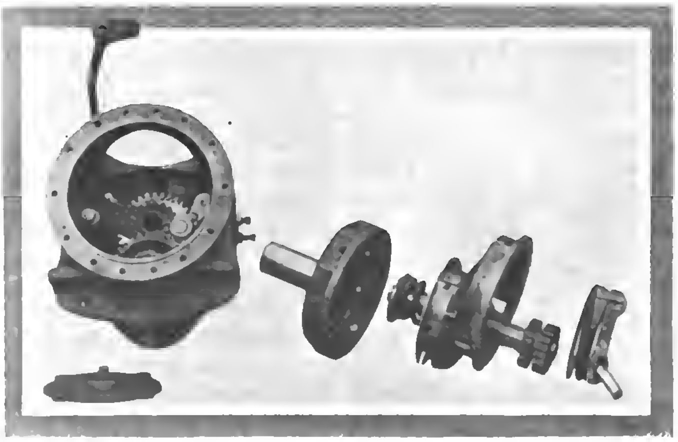

Fig. 5—Two-speed sliding gear, multiple disc clutch, and relating parts, with housing and details

Fig. 1—Three-ton chassis showing power plant in front, radiator above, and fuel tank which comes under driver's seat.

"WE guarantee service" is printed on the cover of the catalogue issued by the Grabowsky Power Wagon Company, of Detroit, Mich., and the title illustration of this article depicts the chassis which is responsible for the results attained. While the makers have a line of commercials to place at the disposal of users, the fact remains that the 3-ton power wagon, as shown in the chassis, as well as in the service of a brewery, as offered in Fig. 2, is the leader of the line, and the many nice features which will be uncovered by a close inspection, are well worth enumerating.

Demountable Power Plant a Conspicuous Feature—All models of this make are so contrived that the power plant may be removed or replaced in less than ten minutes. In this way it is possible to run a number of these cars in service, and by having one extra power plant, a repair can be made without laying up the wagon. The double opposed motor and all its accessories are located as a unit, at the front end of the chassis frame, and the radiator is placed at a point back of the power plant, but in front of the driver's seat.

Obviously, it is an advantage to have the power plant open to easy access, rather than under the driver's seat, and with the radiator placed above the motor, the thermo-syphon system of cooling may be employed to the greatest advantage. In a sense there is nothing new about this advanced method of nesting the machinery, so far as Grabowsky practice is concerned, but there are little refinements to be noted, as for illustration, by means of a register, the heated air, from the radiator, is guided into the cab of the car, and the driver is kept warm thereby. If the weather is not inclement, the register may be closed and the heat is deflected so that the cab will not be too warm.

The thermo-syphon radiator, instead of having the filler on top, has it at a point about one-third down, from the top, at one side. In consequence of this, the remaining upper third of the radiator has no water in it at all, and as the water bursts into steam, the latter rises to the top, and then condenses. The steam cannot ooze out and become a nuisance as well as a source of loss of water, because it is entrapped, and owing to the high temperature (that of steam at the atmospheric pressure) the efficiency of heat transfer is very high, and in this way the good results experienced are accounted for.

Fig. 2—Three-ton power wagon in brewery service, with open cab, steel wheels, dual rear tires, and a full load

Sturdy Vigorous Motor Practice—The double opposed, water cooled, 40-45 horse power motor, with 6 x 5-inch bore and stroke respectively, of cylinders, is designed especially for truck service, has a relatively heavy flywheel to assure that the motor will not stall under severe conditions of service, and the oiling system is absolutely automatic, brought about through the use of a pump driven from the camshaft. In the design of the crankcase, a chamber is provided for the excess lubricating oil, and it is the duty of the pump to force oil in to all of the bearings; excesses drain back to the chamber.

The camshaft is of special steel, with hardened integral cams, and it is so placed that it is readily removed and replaced, besides facilitating the straight line motion which is necessary if good timing is to be counted upon. The half-time gears are pressed on and properly keyed, are of liberal proportions, do the work without making noise, and the bearings, not only for the camshaft, but the crankshaft, are of a fine grade of white metal, of liberal length, and fitted by hand scraping.

The timer is placed on the end of the camshaft where it extends out from the case, and in view of the location of the motor in the chassis, the timer is accessible. The main bearings of the motor may be removed at will and the method of assembling is such that a mistake on the part of a new man at the task is quite out of the question. The valves are large, reciprocate in long guides, and a suitable adjustment is provided at the tappet ends to enable the timing to be done with great precision.

Besides all the care exercised to assure that the motor will give absolutely no trouble on the road, provision is made for quick work, if for any reason trouble should be experienced. In order that an inspection can be made in short order, a cover is placed on the top of the case, and it is large enough to uncover the camshaft and other working parts. Besides this, at the expense of removal of four nuts, it is possible to remove the camshaft from its position and then the crankshaft will be so exposed that the bearings will be accessible and may be adjusted if necessary; a point not always so carefully provided for.

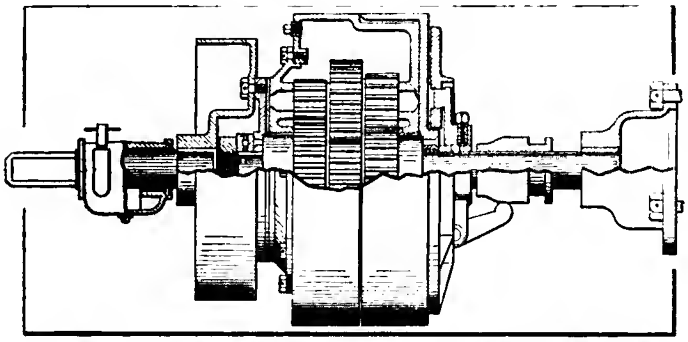

Fig. 3—Planetary transmission, opened up to show integral planets in a grease tight case and other nice design features

Planetary Transmission of Great Value—The planetary gear system is a part of the self-contained power plant, and by removing the plant the transmission comes out with it and may be overhauled at the same time. The planetary gear, as shown in Fig. 3, has a pinion on an extension of the crankshaft and planetary gears revolving around the same. The planets are duplicated to assure a correct balance, and the three gears of each set are cut integral, on Fellow's shapers, using special steel. The gear gives two forward speeds and reverse, and the clutches are so liberally designed that the driver may not destroy the facings even if slipping is tolerated. The gears are so nicely cut and fitted into the case that noise is eliminated, and when the case is properly filled with lubricant wear is rated below a remote contingency. The thrust of the clutch, which is

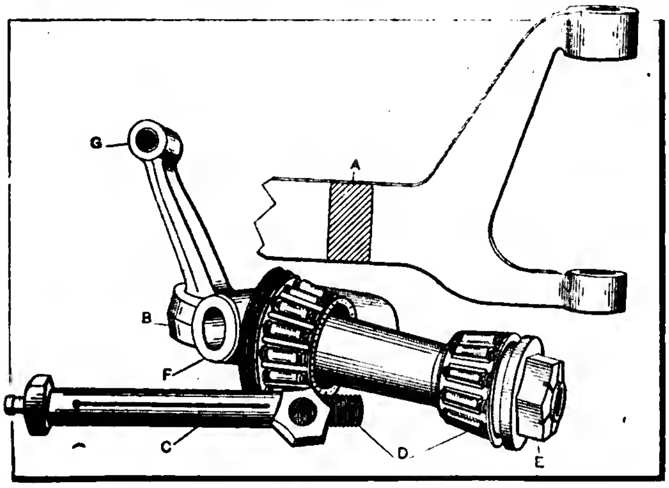

Fig. 5—Knuckle end of front axle, knuckle, bearings and knuckle pin of special steel

but slight, is taken up by a suitable ball bearing, and due to the use of liberal bearings throughout, coupled with fine workmanship, the transmission system is capable of performing its important functions, even in the hands of men of no skill, without showing depreciation worthy of notice.

Chassis Features of Noteworthy Purport—Steel wheels are used in all cases unless the purchaser elects to the contrary. Fig. 4 depicts a section of one of the steel wheels, and besides great strength, this type of wheel is proving to possess peculiarly advantageous properties, according to the Grabowsky experiences, among which resilience is mentioned. The construction of the steel wheels is such that lateral efforts are adequately cared for by using two discs of steel dished in and out, and they, in turn, clinch a ring of wood which is clamped between the bub flanges. Additional strength is imparted to the wheels by virtue of spoke-shaped contouring, which is done in dies, and this shaping also has the advantage of giving to the wheels the general appearance of spoked wheels.

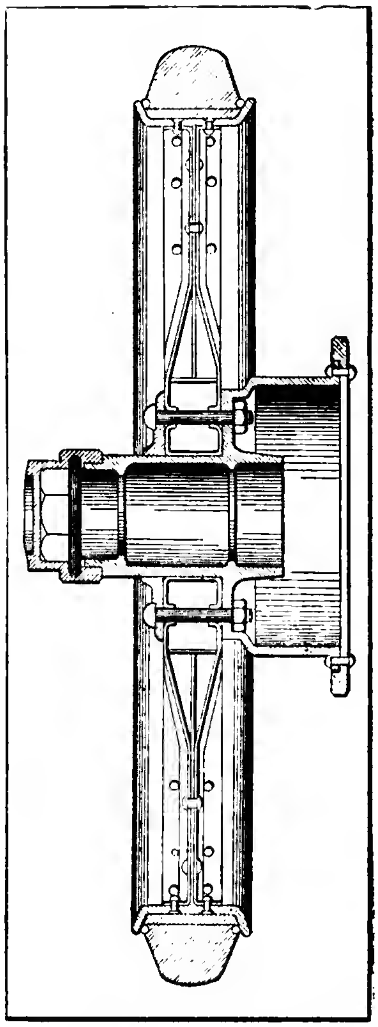

Fig. 4—Section of a steel wheel showing wood rings to which the discs are clinched and reinforcing methods.

The solid rubber tires are clinched in place in the usual manner, with tires in front, and dual tires in the rear, thus affording adequate tire capacity and reducing the cost of tires per ton mile to a minimum in expense accounts.

Side-Chain Drive with Special Features—The large sprocket wheel which is an integral part of the rear wheel hub, on each side, accommodates sprocket chains of liberal size, and passes around sprocket pinions placed on the jackshafts which extend out on each side of the unit system for the differential and bevel gear set. This unit system of housing for the bevel drive and differential is not unlike a live rear axle excepting that it is placed under and suspended from the chassis frame at a point in front of the rear axle. The advantage of this system over the conventional method lies in the ease with which the whole unit may be removed if the occasion requires, and strains are kept from distorting the chassis frame and destroying alignment of the rotative members.

Steering Methods Show Strength—The front, as well as the hind axle, is of the rectangular section, sufficiently large to assure a wide margin of safety, and the knuckles, which are die forgings of special steel, are designed to accommodate the steering road wheels wtih Timken roller bearings, as shown in Fig. 5. *A* represents the axle, *B* is the knuckle, *C* is the knuckle-pin, *D* the taper roller bearings, and *E* the castellated lock-nut which holds the wheel on. The bushings *F* and *G* are a fine grade of phosphor bronze, and purposely made thin enough to abort deformation, which would follow were they very thick of walls. The knuckle-pin, made of a special grade of steel, heat treated, is grooved to facilitate the flow of oil, and in view of the method of heat treating the knuckle, as well as the pin, it is believed that the system embodies a wide measure of safety as well as

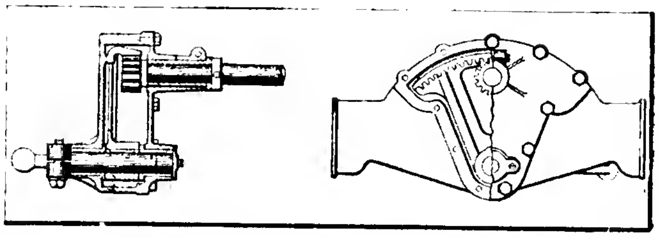

Fig. 6—Steering gear, opened up to show pinion and sector, liberal bearings and grease tight housing

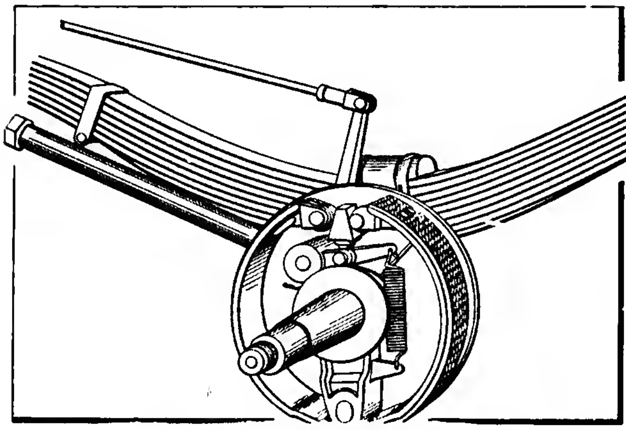

Fig. 7—End of rear axle with wheel removed, showing brake-drum, band, facing, and toggle system

behaving nicely under severe road conditions when the trucks are heavily loaded.

The steering gear proper is of the pinion and sector type, as shown in Fig. 6, sectioned at *A* and cut away at *B* to show how the pinion meshes with the sector. The sector is of large diameter, and the pinion has the minimum number of teeth safety considered, so that the ratio of reduction is in full accord with the best practice. The pinion is cut integral with its shaft so that strength is in no way depending upon a key or other insecure means of fastening the same to its shaft. The whole system is properly housed, runs in grease, and is easy to get at owing to covers being placed where they will do the most good. The steering arm is of special steel, heat treated, and the ball *a*, shown in the section *A*, is of large diameter, hardened, and fits in a socket, with means of take-up, to be utilized as the occasion requires.

Brakes of Durable Design—To properly cope with this problem it was deemed expedient to provide three sets of brakes, two of which are in the rear wheels, of the internal expanding order, as shown in Fig 7, cut away to disclose one set of faced shoes, which are 2½ inches wide. The emergency brake, 10 inches in diameter and 2½ inches wide, is located on the engine shaft next to the transmission. The propeller shaft is of good diameter, runs in a straight line in all planes, yet even so, a universal joint is provided in order to care for frame deflections, which must be taken into account.

With a surfeit of power which is a Grabowsky claim, and the over-loading which cannot be governed, it is necessary to allow for deflections, provide a superabundance of brakes and have all the members so strong that they will not fail in an emergency. These points are rarely ever taken into account in a theoretical discussion of the subject, and in all probability experience only will lead to assured results. The chassis frame is of the channel section, 4⅛ x 2¼ x ¼ inches, of special steel, so braced laterally as to render the structure capable.

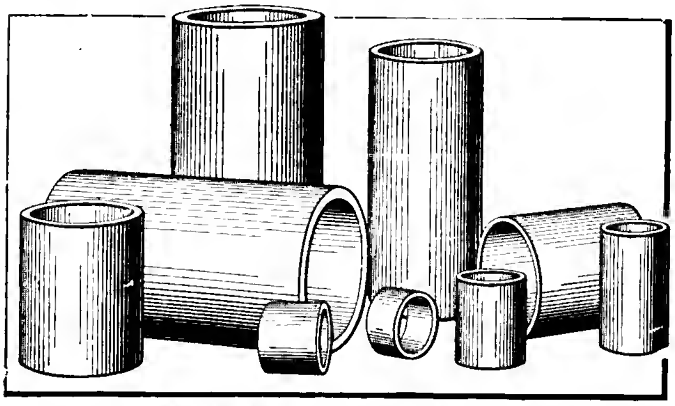

Fig. 8—Bushings used at every point, made interchangeable in order that repairs will be cheap and quickly made

Three-quarter platform springs at the rear are fastened to the rear cross member by a strong steel casting, and hot riveting at every point has the advantage of clamping the riveted members into close relation, due to the care with which the riveting is done and the shrinking which takes place when the rivets cool off. The rivet stock is of a character which will not deteriorate when it is heated, and the pneumatic riveters do the work so nicely that good results are a normal expectation. The front springs are of the half-elliptic type, wide, of a fine grade of spring steel, and while the number of plates change under the several conditions, yet even so, the loading in front is so nearly constant that half-elliptic springs for the front are satisfactory.

One Prime Idea Dominates Everything—The most important detail of design of the Grabowsky power wagons has been retained to the last, and Fig. 8 portrays, better than words, the system of bushings used in the several bearings. They are so fashioned that, should a bushing wear out, all that is necessary is to replace the same wtih a new one from stock and the unit will then be as good as new. The idea of the designer is that every bearing in the wagons will be so easy to keep in order by this means that there will be no excuse for laying a wagon up even for a short while. The bushings are low in cost, require little space for keeping, and by having a set in stock every owner of a Grabowsky will be in a position to do his own repair work at small cost and with no loss of time.

Some Commercial Phases of the Grabowsky—The whole line of cars, as well as the 3-ton chassis here discussed, are uniform in design, and what is true of one is also descriptive of the remaining models. The line includes everything from a 1-ton truck or delivery wagon to the largest size for which there is any demand, and the uses to which these power wagons are put includes sight seeing, trucking, delivery service, etc.

NEW BOOKS FOR AUTOMOBILISTS

"Carburettors, Vaporizers and Distributing Valves" as used in internal combustion engines, is the title on one of the best recent additions to the library of the automobile enthusiast or engineer. In this work the author, Edward Butler, has attacked the subject with typical English thoroughness, and the result is a book that is well worth having. From the point of view of the automobile engineer it is to be regretted that so many of the excellent illustrations are drawn from stationary practice, but this can be overlooked when the unusual number and character of these same illustrations is considered, many, if not most of them, being shown in print for the first time. The only other regrettable feature of the whole twelve chapters is the author's very evident featuring of his own inventions, which, however meritorious they may be, ought not to be so exploited.

Starting with the first carbureters, the author carefully traces out the development of the up-to-date devices for fuel vaporization, not in a historical way, but from an efficiency standpoint. The extent of Chapter 12, devoted to slide valves, may fairly be taken as a measure of this, the whole twelve pages being devoted to the latest practice. This matter concludes the book and follows twelve equally excellent pages on rotary distributing valves. Since the valves and valve action is so closely allied with the fuel question, and any treatment of the latter must include proper treatment of the former, Chapters 9 and 10 will be of more than passing interest. The former is entitled "Water-Cooled Exhaust Valves," while the latter deals with "Admission Valves and Combined Valves for Large-Powered Engines." Coupled with the extended interest in two-cycle motors and their well-known fuel vaporization troubles, it is very appropriate that the chapter devoted to "Two-Cycle and Camless Enignes" should be large, the third largest of the book. The 200 illustrations, aside from the complaint above, are very good, having been selected from best English, French, German, Swiss and Belgian practice. This work, from the press of J. B. Lippincott Company. Philadelphia, should be one of the "best sellers" if judged on the basis of real merit.

ELEGANT FRENCH LIMOUSINE IMPORTED BY NEW YORKER

PARISIAN ideas of luxury in automobile bodies are well illustrated in the handsome 50-60-horsepower Renault limousine imported by E. L. Giroux, a wealthy copper magnate of New York City, which was on view at the garage of Renault Frères last week. The chassis is a standard Renault construction, carrying a six-cylinder motor of 120 by 140 millimeters bore and stroke; evidently there will be no lack of power. The wheelbase is very long, approximating 12 feet. The car embodies the usual Renault features of thermo-syphon water circulation, ignition by high-tension magneto with fixed spark advance, four-speed gear with two sliding members operated by a progressive lever, and shaft drive to the live rear axle.

Revealing Luxurious Interior

Mr. Giroux bought the car last spring and had it fitted with an open touring body. With this equipment he made an extensive tour through France, Italy and Germany. Returning to Paris on his way back to the United States, he happened to visit the plant of Kellner, the famous French body builder. There he saw a limousine which was being made to the order of the Czar of Russia. Mr. Giroux liked the body so well that he ordered practically a duplicate to be placed on his Renault chassis.

The limousine body appears through the open door nearly the size of a small reception room. Five passengers are easily accommodated. The two forward seats in the interior, instead of the usual small and uncomfortable stools, are full-size revolving arm chairs, and the occupants can swing around to face either forward or back without disturbing their companions. The interior woodwork is mahogany and the upholstering silver-gray velours. The finish in wood has many advantages over the old method, in which that part of the interior not upholstered was covered with cloth. The wood finish is preferred by many for its appearance, but is also easier cleaned and retains longer its freshness. The interior fittings show the designing of an artist of no mean ability. The electric lights are supported on little figures of angels, richly gilded.

Most striking in their novelty are the side lamps, which, as is rapidly becoming customary with limousine bodies, are carried on the body framework back of the driver's seat at a considerable elevation. Also following the most modern practice, these lamps are electric, thus avoiding the unpleasant heat and odor inherent in oil lamps. The shape of the lamps is particularly elegant. Each has three windows of a graceful outline tapering to the bottom; these are set so as to occupy about one-half of the circumference of the lamp. The further equipment of the car includes two powerful headlights and two horns, one an electric siren and the other a four-tubed device which gives a call similar to that of a bugle. The mudguards and running boards are very wide and are supplemented by aprons extending to the frame. Although by intent a town car, the machine's great power gives it considerable ability as a tourist.

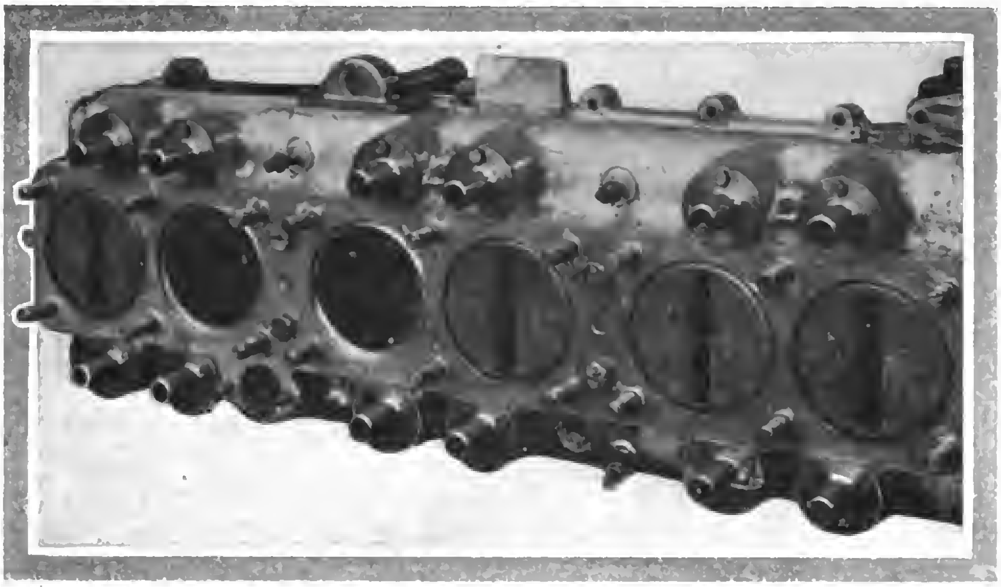
LUBRICATING SYSTEMS REFINED TO AVOID TROUBLE

WHEN a little excess of lubricating oil accumulates in the crankcase of a motor it is prone to splash up and be sucked by the piston (on the suction stroke) into the combustion space of the cylinders, causing ignition trouble and accumulations of carbon which will end in knocking. In passing through the plant of the Pierce-Arrow Motor Car Co., at Buffalo, a few days ago, the writer noticed the way in which this possibility is prevented by the simple process of fitting slotted covers over the cylinder openings of the crankcase, the slots being for the connecting rods to play in, as will be seen at a glance.



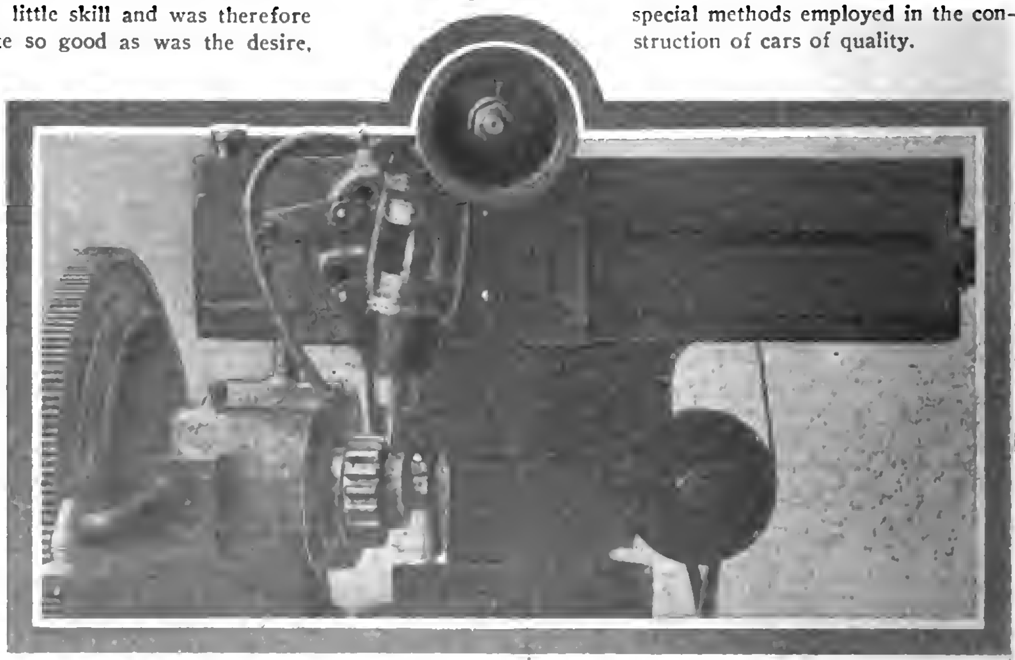
Baffle Covers Fitted Over Crankcase Openings to Prevent Oil Splashing

This form of baffling the excesses of lubricating oil was originally brought out in connection with double opposed motors, and is used on the Reo in order that excess of lubricating oil will not be experienced in the rear cylinder, it being the practice in Reo cars to place the motor so that the cylinders are in the fore and aft plane. The idea worked out very well indeed in this car, and it should be of good advantage in a six-cylinder motor, even if the cylinders are vertical, for, with a rather long crankcase, it is just possible that a little excess oil in the crankcase might pile up at one end when the car is negotiating a steep grade and produce lubricating trouble. True, in the Pierce cars the means for lubrication are so well applied that this extra precaution, as illustrated, comes as a safety measure rather than as a necessity.

AUTOMATIC CHAMFERING PROCESS FOR GEARS SAVES COST

FORMERLY it was the practice to hand chamfer the teeth of sliding gears in order to provide the wedge shape which is necessary to enable them to engage readily when sliding into the respective speeds. The hand process was slow, had to be conducted by men of more than a little skill and was therefore costly. The results were not quite so good as was the desire, owing to the differences which will always be present when hand work is depended upon, it being impossible to realize exactly the same degree of accuracy from any one man on different days, to say nothing about differences which will exist between different men.

Fortunately the efforts made to reduce this process to an automatic-machine basis has succeeded and the machine now used for this purpose is here depicted, showing the gear in place on the "mandrel" and the chamfering tool just entering to make a cut. This tool belongs to the vertical milling-machine class, and for this work is provided with motions to impart to the milling cutter the ability to skirt around the end of the gear tooth, to give it a wedge shape, and to back off, register and enter again for purposes of cutting, which it will do as many times as there are teeth in the gear. The photograph was taken at the plant of the E. R. Thomas Motor Company, at Buffalo, N. Y., and is but one of the many special methods employed in the construction of cars of quality.



Profiler Leaves More Face Than That Due to Hand Work

Bablot In a Brasier Making Fast Time In His Approach to the Foot of the Hill

GAILLON'S CLIMB HAD BABLOT FOR STAR

PARIS, Oct. 15—Bablot, driving Brasier's four-cylinder Grand Prix racer, made the fastest time in the eleventh annual Gaillon hill climb. With the car built for the late Leon Thery, and driven by him for the last time in the 1908 Grand Prix, Bablot romped up the Normandy hill in 28 2-5 seconds. This is 2 1-5 seconds slower than the same driver's time last year, and is far behind the world's record set up by Lee Guinness with the famous eight-cylinder Darracq sprinter, which climbed the hill in 25 flat, at an average speed of 89 miles an hour. The slower time is largely explained by the fact that for six hours previous to the start of the hill climb rain had fallen continuously. It had been necessary, in fact, to postpone the start from morning until noon in order to give the competitors a reasonable chance. Even this did not allow the course to dry thoroughly.

Joerns, on a German Opel car built in expectation of a 1909 Grand Prix, made the second fastest time, with a climb up the hill in 30 seconds. The car conforms with the regulations issued for the Grand Prix race announced for this year. When the race was abandoned, almost immediately after it was announced, the Opel company found themselves with three special 130 millimeter cars on their hands which they have only been able to use for hill climbing and demonstration events. Gaste, with a six-cylinder Rossel, put up 32 seconds.

In the racing voiturette class, for one-lungers with a bore of 3.9 inches and a stroke not exceeding 10 inches, Lion-Peugeot continued its series of victories, Giuppone getting up the hill on his high-bonneted monster in 46 1-5 seconds. A Corre-La-Licorne climbed the hill in 57 seconds, and Crespelle went up in 59 2-5 seconds. Georges Sizaire, who came forth at the eleventh hour with the intention of pitting his Sizaire-Naudin one-lunger against the eternal Lion-Peugeot rival, found that he was geared too high for hill work, and had to retire.

Page, driving a four-cylinder Motobloc, made the best performance in the touring classes. Though having a bore of only 3 1-2 by 5 1-0 stroke, he made the excellent time of 47 2-5 seconds, beating cars of much larger dimensions. For the tourists a classification was made on an efficiency formula. Under this the Motobloc came out first, with an efficiency of 0.847. The others in order were single-cylinder Sizaire-Naudin, 0.829; single-cylinder Crespelle, 0.824; four-cylinder Delage, 0.811; four-cylinder Rolland-Pilain, 0.793, and single-cylinder Hurtu, 0.756.

NEWS BUDGET OF LATEST BRITISH AUTO AND AERO DOINGS

LONDON, Oct. 15—The Government's Development bill, which provides for the expenditure of the money raised by taxation of motor cars and petrol, is still far from settlement, but apparently the final arrangement will be considerably more favorable to motorists than was expected. The framers of the bill were strong on the matter of special motor roads (or "speedways," as they were soon styled), but the opposition of the various motor organizations has resulted in these ideas being dropped, and, instead, the major portion of the money will be spent on the improvement of existing main roads, particularly in the direction of making them dustless. A few new roads may be constructed,* but these will be open to all forms of traffic, and no speeding will be permitted.

As regards the tax itself, the Government states that a nominal power rating—such as the R. A. C. formula originally proposed—will not be used; instead, some means will be brought forward to measure the power actually developed. Details of this plan will be interesting, and at the same time the new arrangement circumvents those makers whose 1910 cars have been designed to come just within the R. A. C. rating standards originally announced. Another important concession is that no tax will be imposed on visitors bringing their cars to this country for touring purposes.

The auto buggy has made its first appearance over here. A Coventry firm has taken up the agency for the Duryea "Buggyaut," and the first car is already on the road. The type is something entirely new to the British motorist, and, as may be imagined, a great amount of interest is evinced in its construction. From the number of inquiries received, the agents are convinced that there will be quite a good market for this vehicle.

Interviews with Lieut. Shackleton since his return from the South Polar expedition have revealed his strong belief in the advantages of motor transport for exploration work of this kind. The special Arrol Johnston car which he took with him did good service, and had the vehicle been of the sledge, instead of the wheel, type, it would have been used for the final stages of the journey over the soft snow of the Barrier. The new expedition, in charge of Capt. Scott, will be provided with motor sledges, but details of their construction are not yet available.

Additional to the descriptive article which recently appeared in THE AUTOMOBILE, referring to the new British styles in motor bodies, the accompanying photographs show further developments of the "Torpedo" style. The last car is particularly graceful in its lines, and it is the property of F. A. Bolton, a well-known Midland automobilist. The first illustration shows one of the 57-horsepower six-cylinder Daimlers, with valveless engine, purchased by W. R. Conill, of New York, for use on an extensive European tour. It will be noticed that both cars are equipped with detachable wire wheels,

*In the form of loops round big towns.

different methods being adopted for carrying the spare wheel. The adoption of this by an American will be watched with particular interest, for this type of wheel has made so little progress there.

How Matters Aeronautical Are Progressing in England

Matters aeronautical are progressing apace at present, and before another month is completed there should be much to record. The two principal events on the list are the attempts for the *Daily Mail* $50,000 prize for the journey from London to Manchester, and also the Aviation week at Blackpool.

The distance from London to Manchester in a straight line is 180 miles, and during the journey two stops will be permitted for the purpose of replenishing the fuel tanks. Col. Cody is the first to make active preparations for the attempt, and during the past week he has been carefully mapping out route and selecting numerous suitable landing places, so that he may be able to make his two stops according to his convenience during the flight. The acompanying photo shows Col. Cody on the occasion of his visit to Coventry, which is exactly half-way between the two places. Additional interest is given to the picture by the fact that Col. Cody's mentor is Charles Y. Knight, who is busy demonstrating the advantages of the Knight-Daimler engine.

Cody's attempt will take place in the next few days if the weather is suitable; in the meantime larger fuel tanks and an extra water supply are being provided on his machine.

It is not unlikely also that Blèriot will make the attempt, in spite of the published statements that he is retiring from competitions for the present. As the result of Blériot's recent visit, the announcement is made that the Humber Co., of Coventry, is commencing straightway the manufacture of Blériot monoplanes. Inquiries show that this is quite correct, and that at its mammoth works the Humber firm has already got out specifications for the first batch of 100 machines. The list price has been fixed at $2,000 each. The Humber Co. has also secured sole rights for the manufacture of the Farman machine, and as Mr. Farman is arranging to stay at Coventry for the next few weeks, it is quite possible that he, too, will endeavor to make the journey to Manchester.

The Blackpool Aviation week is now definitely arranged to commence October 18. Contracts to appear have been signed by Farman, Paulhan and Delagrange, and the Société Ariel has promised to provide two Wright machines with competent pilots. An excellent ground has been secured two miles from the town, and stands are being erected for 15,000 persons.

BRITISH DUST-LAYING EXPERIMENTS

London, Oct. 12—The Roads Improvement Association has just issued a report on the recent trial of calcium chloride as a dust preventive. Calcium chloride is produced in large quantities as a by-product in the ammonia-soda process of manufacturing common washing soda and in certain other chemical process. In its common form the chemical contains 40 per cent of water, but other definite varieties have 25 per cent water or even less. The common form costs $12 per ton at the works. In all its states it has in a marked degree the property of absorbing moisture from the surrounding atmosphere, and if left exposed to damp air it eventually becomes a thick syrupy liquid through the absorption of moisture. If then it is exposed to a dry atmosphere it will gradually part with some of this moisture till it regains its original condition. It is on this property that the utility of calcium chloride for laying dust on roads depends.

The chemical was tried both in the wet and the dry methods. In the former the granular chloride was dissolved in water in the proportion of one hundred weight to each 100 gallons, and this solution was sprayed on the road from a watering cart. The second method was effected by distributing the chloride dry over the surface of the road. Two consecutive half-mile stretches on the main London-Staines road were treated in the two ways on June 12 and careful observations were then made each day till August 12. The result of the observations demonstrated that while both methods were effective in laying the dust to a marked extent, the dry method of applying the chemical gave more lasting results than were obtainable with the wet method. The total cost was $26 and $16 respectively, so that the dry method would seem to be undoubtedly the more advantageous.

The association is bringing the results of the experiments before the notice of all country surveyors, and it is expected that during next Summer an organized attempt will be made to lay the dust on all main roads passing through populous parts.

Queen of Siam Orders a Napier—An especially fine piece of body work was that done on the Napier omnibus body purchased for the use of the Queen of Siam. Round the royal palace at Bangkok there are miles and miles of fine roads, through which the ladies of the court have been in the habit of walking. Now, having adopted a more modern means of locomotion, they will doubtless cover a greater country, and more pleasantly.

A Particularly Graceful British "Torpedo" Body—Property of F. A. Bolton, a Midland Autoist.

INTERNATIONAL TOURING CONTROL

"Bureaucracy discomfited" might summarize the story of the Paris international congress for the regulation of automobile traffic. Thousands of gilt-braided officials, whose sole duty has always appeared to be to prevent anybody from ever accomplishing anything, face the loss of their snug positions and the necessity of working for a living like ordinary mortals. Truly it is deplorable. The volubly polite, regretfully firm Frenchmen—"But, monsieur, it is impossible!"; the erect and soldierly Germans, with heads of a most surprising woodenness; the Italians, those graceful cigarette smokers, all are doomed. Perhaps the American tourist will shed a parting tear.

Like most other great reforms, the only thing remarkable about the proposed international passport is that it was not thought of long ago. There are no real difficulties whatever in its application. Nobody gets any money out of the triptyques and customs deposits, except the bonding companies which hold the stakes. The countries which enter in the agreement will actually receive a direct financial profit from the saving of the wages of the many officials now necessary. Examinations of automobiles to ascertain their suitability to road conditions, and of drivers to test their operative skill, might just as well be made once for all, and their results accepted wherever car and driver may go. The German examiner does not believe that the French examiner would be wilfully mendacious, but rules are rules, and he must make a pretense at least of earning his salary. So it goes, each country stupidly duplicating work which had been done before. One illuminating flash of intelligence suddenly reveals the absurdity of the old system, and makes a reform almost inevitable.

This convention, it must be emphasized, is not a gathering of club members, uncredited save by private organizations, merely to air their grievances. Each delegate officially represents his government, and in many cases has full power to act for it. The resolutions passed by the convention are practically certain to be adopted in England, France, Belgium, Germany and Italy. Moreover, the program of the convention covers practically every subject of legislation of interest to the automobilist except that of speed limits. Although it would be desirable to include this as well, everyone recognizes the fact that speed depends too much on local conditions and sentiment to permit any agreement at present.

Of even greater moment to the automobilists of this country is the paragraph in the story of the convention which explains that, although the United States has a representative in the convention, he is unable to act in behalf of his government. Picture the amazement of the European delegates when they learned that the United States, although supposedly a single country, was divided among itself exactly the same as the different states of Europe, and that before it could take active part it would first need a similar convention of its own. It is by no means a flattering testimonial to American progressiveness and initiative.

"BUILT ENTIRELY IN OUR SHOPS"

In the parts industry to-day the press of business is so great that the parts maker must refuse orders. The disgruntled maker having his order refused, decides to make his own parts hereafter, and so the parts maker loses future business. Since the latter is so overworked at present, he does not mind this in the least.

But this congestion is going to result in more manufacturers installing tools and equipment so as to be able to make their own engines, transmissions, etc. This will mean that more cars will come under the class of "built entirely in our own shops," the advantages of which no one denies. More than all that, although not quite so close to the manufacturer's and user's hearts, is the influence on trade as a whole.

This is bound to be beneficial, for with more capital invested in land, buildings, and equipment, any business assumes a more stable position. So, too, as to the disposal of the resulting cars, the greater the output, the more care that will be used in disposing of them and in creating a stable market so as to keep the factory busy at all seasons. This should settle down very soon—there are many indications that some firms have already done so—to a business of unwonted stability with the "hot air" and "flim-flam" all eliminated, as well as the season and the model bugaboo, so that the automobile industry as a whole will line up alongside of the typewriter, furniture, clothing, and other similar businesses. These, in a broad way, may be said to have no seasons or models, and their yearly business is very carefully worked up in a quiet way, without any of the hysterics which have attended the automobile business in the past.

FOR MUCH NEEDED INTERNATIONAL RULES OF THE ROAD

By W. F. BRADLEY

PARIS, Oct. 15—Eighteen nations represented by sixty-three delegates are united in Paris for the purpose of making automobile regulations throughout Europe as uniform as possible and thus abolishing the difficulties in the way of international travel. The delegates are not representatives of automobile clubs, but the accredited representatives of their respective governments, having in nearly all cases full power to act for them. The congress is one that means business.

Europe has the misfortune to be divided into a score of countries, each one of which has its own way of controlling automobile traffic and its own conditions of admittance into its territory. As the automobile has made touring among these different countries almost as common as road intercourse among the different States of the Federal Union, the authorities have awakened to the disadvantage of individual laws, hampering travel and hindering free intercourse. Germany asked France to call together a conference to consider this question. France willingly acceded and every nation in Europe accepted the invitation.

America also asked to be allowed to come in, with the result that William S. Hogan, the A. C. A. delegate in Paris, was officially appointed by the Secretary of State. But America needs internal reform before she can usefully participate in a congress for the uniformity of automobile regulations, and it was this point that Mr. Hogan was instructed to make clear. Until there is a Federal automobile law it is impossible for the Secretary of State to give anybody power to sign an automobile traffic convention on behalf of the United States. The opinion of the American delegate is that this movement in Europe will help forward a Federal automobile law more than anything else. If Europe, with its score of nations speaking different languages, having different tariff rates and different customs, can come to an understanding on automobile circulation, why should not the United States of America?

Summary of What Is Wanted

There are nine distinct items on the program, as follows:

(1) Conditions to be fulfilled by all automobiles before being put into circulation.
(2) Conditions to be fulfilled by drivers of automobiles.
(3) International recognition of driving certificates and national registration numbers.
(4) The types of registration numbers, and the way in which they shall be carried.
(5) Types of horns and other signaling apparatus.
(6) Rules of the road covering overtaking and passing other vehicles.
(7) Road signs and danger signals.
(8) The recognition of road regulations in force in each country.
(9) The creation of frontier stations and customs offices authorized to carry out the formalities provided for in the international regulations.

Under Article 1 will be set forth the various conditions that an automobile must fulfill before being put into use. Thus, in France, for instance, before a car can go on the road it must be examined by a government engineer and meet certain requirements regarding brakes, freedom from explosion, fire, noise and disagreeable smell. There are several countries, America and England among them, which have no such examination. But custom has gone even further than the government regulations, and there is not a car built by a reputable firm which could not come up to the standard of safety proposed by the congress.

Article 2, dealing with drivers, is a more knotty problem, for the congress proposes that a severe examination on the lines of that already existing in France shall be instituted. No person under eighteen could hold a driving license; in every case an examination of ability must be held and each nation would have the power to withdraw the licenses where the authorities saw the necessity for such a course. To introduce such a scheme every nation would have to be prepared to undertake a certain amount of internal reform.

The first two points agreed upon, the third follows naturally, for if a common understanding has been arrived at on the examination of cars and the issuing of driving licenses, there is no reason whatever why a New York registration number should not be accepted in Paris and a New Jersey driving license received without question in Berlin. It is understood, of course, that New York will only issue registration numbers under the international regulations and that New Jersey will examine its drivers and license them on the same international basis. But this should not be impossible.

The size of the registration figures and the way in which they shall be carried is not a matter likely to cause any difficulty. Article 5, dealing with types of horns, is also readily settled.

Turning Left Not Likely to Be Adopted

Article 6, dealing with rules of the roads, is a difficult point. All the States in the Union follow the common rule of keeping to the right. In Europe it is not so, the majority keeping to the right, but England having a rule that all traffic shall keep to the left. Curiously, in certain countries, notably Italy, the two rules are in force, in some towns it being necessary to drive to the left and in others to keep to the right. The congress appears to favor an international driving law under which all vehicles shall keep to the left, as is done in England. With the driver placed on the right-hand side of the car, it is claimed that this is the safest rule. It is doubtful, however, if it can be passed, for the change is so drastic that every nation will hesitate to make it. It is certain, however, that those nations that have the two rules in force will have to select either one or the other.

Road signs and danger signals can readily be agreed upon. Indeed, a basis for action has been made in the signs without lettering now used in France and various parts of Europe and recently approved at the international automobile congress. Some of these signs were used in the 1907 Vanderbilt race.

The recognition of road regulations in force in each country is also a matter that should not cause much difficulty. If, as is probable, it is found impossible to establish international driving rules, it is not difficult for each nation signing the agreement to make the necessary detail internal improvements and simplifications and agree to recognize the laws of the other nations. It is, in fact, merely a continuation of the present conditions.

Vexing Matter of Customs Duties

Article 9, on customs and frontier stations, particularly interests Europe and Americans who tour Europe. The present improved system consists of the issuing of triptyques by the various touring associations. Thus, if you are an American and wish to visit France you can, before leaving home, arrange with the Touring Club de France, deposit your duty, receive in return a threefold piece of paper and enter France as easily as crossing the East River. The same can be done for several other European countries. The result is that there is no money transaction at the frontier. You make your deposit through your banker at home and are refunded by him on your return.

The system is a concession on the part of the various custom authorities of Europe. It is a concession, indeed, that is not always sufficiently appreciated by the automobilist, who does not see the years of labor necessary to convert the authorities and the large sums guaranteed by the Touring Club of France and other associations.

The defect of the system is that for each country issued a deposit must be made. Thus the American who intends to do Europe thoroughly has to obtain about half a dozen triptyques and make a heavy deposit with his banker. It is proposed that there should be one international triptyque, and that the amount deposited on it should be equal to the highest tariff of the various contracting countries. Thus, if an American car, for instance, visits Europe, enters and leaves several countries, but enters and does not leave Italy, the officers of that nation would claim that the deposit be handed over to them in payment of duty. This, in fact, is what is done now, with the difference that instead of one single deposit there are half a dozen different ones and half a dozen different triptyques to be carried round for presentation at the various frontier stations where they must be presented.

With the international passport the automobilist would be able to enter and leave any country in Europe—with a few rare exceptions—on the presentation of a paper. The authorities have nothing to lose by such a scheme and the automobilist has everything to gain. In all probability this scheme will be adopted by the nations now issuing triptyques. The nations that have not yet adopted the triptyque, among them being Russia, Turkey, Greece and the eastern states, will doubtless come in later.

AGAIN FRANCE WANTS TO RACE HER OWN WAY, OF COURSE

PARIS, Oct. 15—French automobile constructors have got over their racing fright apparently, for the Sporting Commission of the Automobile Club of France has just decided that there shall be a Grand Prix next year if the principal constructors desire it. The full committee of the club has approved this decision. As the Sporting Commission is composed of representatives of all the leading French firms, especially those having given the greatest encouragement to racing, the probabilities are that the event will be held. A referendum will be taken immediately and a decision arrived at before the end of October. As the race cannot be held until June or July, constructors will have about eight months in which to make preparations.

It has been decided in principle that the 1910 Grand Prix shall be held over a distance of five hundred miles, and that it shall be open to all cars without restriction of bore and stroke or weight. After the Gordon Bennett races the weight limit of 1,000 kilos was continued for a couple of years. Then came a maximum bore of 155 millemeters for a four-cylinder engine. This was fruther reduced by the International Association of Automobile Clubs to 130 millimeters for 1909. Owing to the action of the French constructors, however, no race was held this year, and although a few 130 millimeter cars were built, they have never been tested in a long distance event.

France Wants Rules of Her Own Making

It will be remembered that the 155 milllimeter rule provoked a war between the International Association and the Vanderbilt Cup Commission, which declined to accept this rule. It might be supposed that if an international meeting were needed to frame a racing rule for 1908 and 1909, the same would be necessary for 1910. But this is not so when the French Club is the organizer. It believes that a no restriction rule is the best for the health of the automobile industry, and America, England, Germany, Italy, and Belgium must accept the rule without a murmur.

The proposal to hold a race for cars of any power or any weight is not new. It was brought forward at previous international conferences, its strongest supporters being a group of French manufacturers. It was then feared that the result of such a rule would be the production of such cars as the famous eight-cylinder Darracq sprinter, of Florida fame, capable of doing two miles a minute. Experience has shown that such a car would be its own destroyer on a 500 miles test. Neither in 1907 nor in 1908 did the cars with the most powerful engines come in first. The ability to hold to the road, and especially the wear of tires, much more pronounced on some cars than on others, considerably influenced the results. Partisans of the no-limit rule maintain that it will open a new field of investigation, instead of directing effort entirely into one channel. Something will doubtless be gained in speed, and tires are there to keep weight down to a reasonable limit.

Anjou and Dieppe Both Want Race

It is not yet known where the French Grand Prix will be held. Anjou was promised the race this year, and is still prepared to offer its roads in 1910, together with a subsidy of $20,000 to the club. Dieppe, which had the race in 1907 and 1908, has also come forward with an offer of the same course. Other courses are not lacking, and it may be a month before the Racing Board makes a selection. However the French automobile constructors may regard racing, there can be no doubt that the country people are keenly alive to the advantages to be reaped from such contests. Were it not regarded as practically certain that the choice will lie between Anjou and Dieppe, a dozen other localities would quickly come forward to offer circuits.

A. C. F. Will Also Have Aeroplane Meet

In addition to its automobile Grand Prix, the Automobile Club of France will undertake the organization of aeroplane races next year. This decision has been arrived at on the proposition of Marquis de Dion, approved unanimously by the full meeting of the club. The races will extend over one week and will commence immediately after the great national horse race at Longchamps, marking the height of the fashionable Paris season. It is not yet known where the aerodome will be located, but a site near Paris is most probable. Valuable prizes will be offered. There has been a great rush of former automobile racing drivers into the ranks of the aviators. The drivers find aeroplanes easy to control, and certainly no more dangerous than their former occupation; at the same time the emoluments are by no means to be despised. Among those whose names have often been heard in connection wtih the older sport are Rougier, Gobron, Le Blon and Fournier. Baron De Caters, too, now pilots a Voisin biplane.

GERMAN TRADE STATISTICS

BERLIN, Oct. 12—Some of Germany's foreign trade during the first seven months of the present year shows a slight increase in its exports as compared with a decrease in the number of motor cars sent into the Empire. It may, therefore, be said to be of a favorable nature on the whole, though not of so decided a character as was expected in view of the general upward trend. While the majority of countries have remained true to German cars, Great Britain and France have each bought considerably less; but this is in keeping with France's return trade with Germany. The exact figures are:

January 1 to July 31, Imports into Germany:

	1909 dcwt	1908 dcwt
Austria	570	670
Belgium	1519	1995
France	3441	4039
Great Britain	296	106
Italy	835	910
Switzerland	502	361
United States	53	140

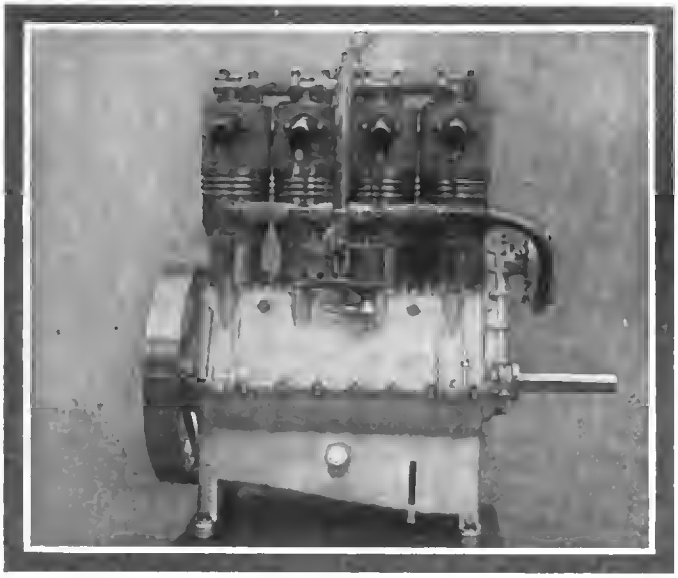
January 1 to July 31, Exports into:

	1909	1908
Austria	2297	1503
Argentine	178	144
Belgium	341	61
Brazil	1	126
Denmark	410	169
France	1209	1752
Great Britain	1196	1612
Holland	600	172
Italy	378	187
Dutch Indies	111	84
Russia	1522	1660
Roumania	318	113
Switzerland	405	241
Spain	193	161
Sweden	184	142
United States	670	240

DE LAMBERT FLIES OVER EIFFEL TOWER

PARIS, Oct. 18—The Juvisy aeronautic meet scored its first great success to-day when Count de Lambert, in his Wright aeroplane, flew from the aviation field to Paris and back, circling over the Eiffel Tower. In a straight line the distance is about 30 miles. The aviator made the round trip in 49 minutes. His greatest height, attained over the Eiffel Tower, is reported to have been 1,300 feet. Orville Wright was a witness.

De Lambert kept his plans secret from everybody except two officials of the Aviation Society, one at Juvisy and the other on the Eiffel Tower, who timed him. The crowd of 20,000 people which saw the beginning of the flight was astonished when the aeroplane started out across country and disappeared behind the hills to the northward. Fifteen minutes later pedestrians along the Seine began to stare upward at what they thought was a large box-kite. They soon saw their mistake, however. The aeroplane rounded the apex of the tower, which is over 1,000 feet high, and then sailed away to the south. Meanwhile the anxiety at Juvisy grew intense. A telephone message informed the spectators of what De Lambert was doing, and when he reappeared, flying at a height of 500 feet, the crowd went wild.



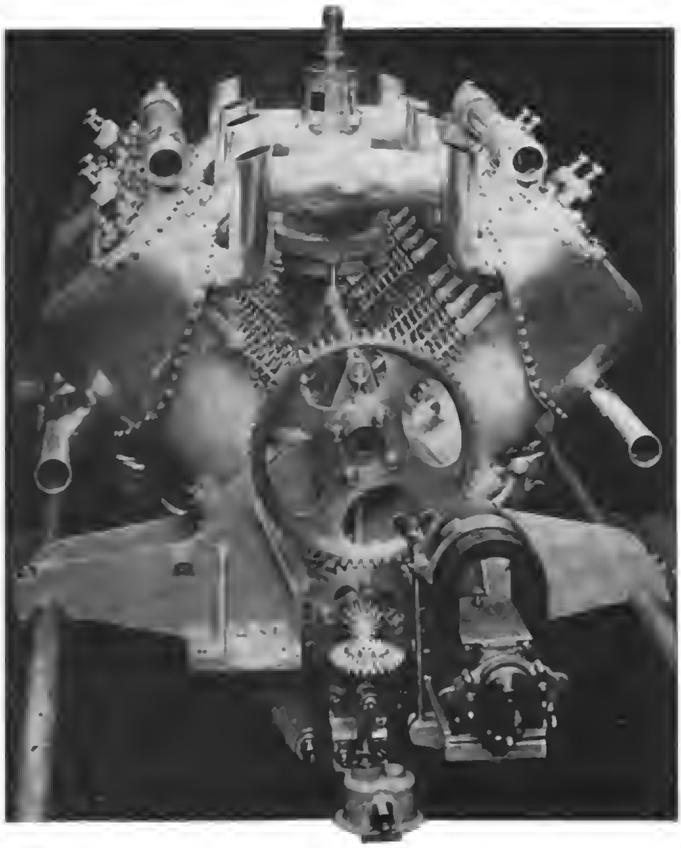
Panhard's 40-Horsepower Aero Motor Has Copper Jackets

THE WOLSELEY AERONAUTIC MOTORS

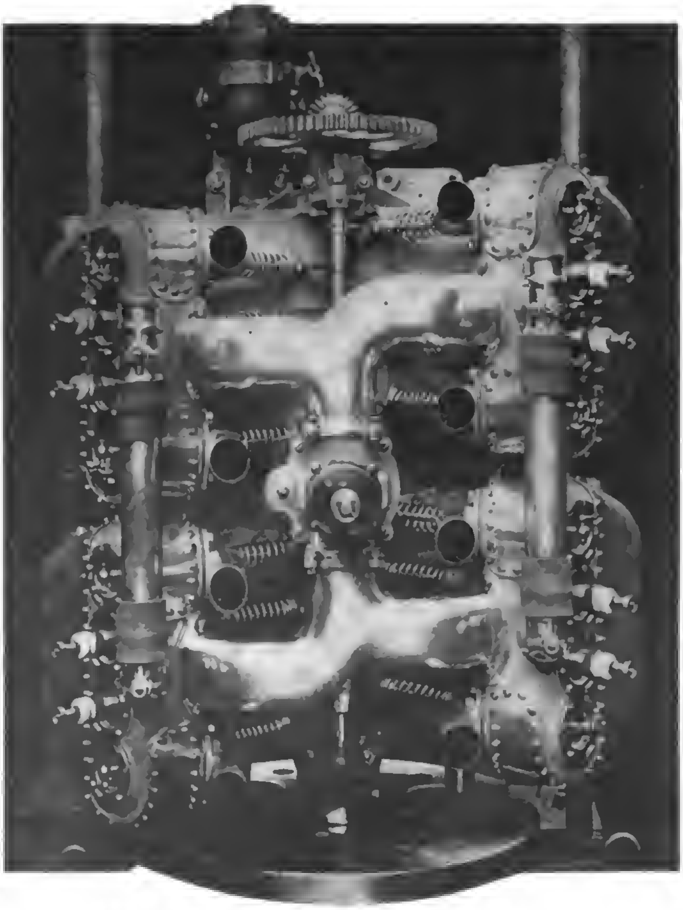
Claiming the championship of the sea with the motor-boat *Wolseley,* the famous English house of Vickers, Sons & Maxim, Ltd., has turned its attention to motors for dirigibles and aeroplanes. A complete series of these, ranging from 50 to 400 horsepower, has been brought out, and, backed by their maker's reputation in the line of cannon, torpedo-boat engines, and similar fine machine work, they should at once assume an enviable position in this new industry.

The smallest motor, particularly adapted to aeroplane construction, is rated at 50-horsepower, but is claimed to be capable of delivering 75. Its eight cylinders are arranged in a "V" to shorten the crankshaft and secure a more compact design. The ignition system, the carbureter, lubrication and water circulation follow automobile practice. The Bosch magneto is used. The carbureter has an additional air intake for use in high altitudes. Lubrication is forced by a centrifugal pump. The water packets are of sheet aluminum, riveted in place upon the cylinders. The motor turns normally at 1200 or 1400 r.p.m.; it may thus have the propeller either fixed directly on its shaft, or driven through a chain or belt affording a reduction in speed.

The dirigible motors, similar to those used in boats, all have vertical cylinders set in line on the crankshaft. They are made in three sizes: 135-horsepower, 6-cylinder, 200-horsepower, 8 cylinder and 400-horsepower 12-cylinder. A new and praiseworthy feature is the spring suspension, by means of four one-quarter elliptic springs, which should entirely prevent any vibration being transmitted to the rest of the machine.



V-Type of Wolseley Engine Has Gears in Front



Wolseley Motor from Above, Showing Peculiar Inlet

S. A. E. WINTER MEETING TO HAVE WIDE RANGE OF SUBJECTS

THE meetings of the Society of Automobile Engineers have each year more decidedly proved the value of this society to the various professional and other interests identified with the self-propelled vehicle. Many of the papers read and discussed at the semi-annual meetings show that, busy as the automobile engineer is, many a one still finds time unselfishly to give to the world in well prepared papers the result of his experience. It is a pleasant thing to record the members of this latest and most important field are as emphatically leaders in this liberal sharing of their knowledge as they are in the broad blazing of new trails for mechanical engineering generally.

No doubt many will be present during one or the other of this winter's shows at New York. Such of these as would care to be present at the professional meeting of the Society of Automobile Engineers may be assured of a hearty welcome. Their contribution to these discussions will be as welcome, as will also more complete papers; the latter should be sent in to the society's offices at No. 2 Rector Street, New York, to be in the society's hands by November 30 for printing and general distribution before the meeting. Papers and discussions from an engineering standpoint, including also matters of operating finances are in order. Among the subjects that discussion at the winter meeting has been asked for are:

"Standardization of Pneumatic Tires."
"Taxicabs—Requirements and Operating Cost."
"Carbureters—Kerosene Carbureters."
"Railway Motor Cars."
"Drawing Room Systems."
"Truck Tires."
"Valves in Head vs. T Head."
"Alcohol as Fuel in Internal Combustion Motors."
"Silencer."
"Radiator, Design and Efficiencies."
"Critical Temperatures, Cooling Curves of Alloy and Other Steel."
"Two-Cycle Motor Efficiency and Results."
"Journal Loads in Transmission Gears."
"Placing Society on More Professional Basis."
'Efficiency of Spur, Bevel Worm Gears and Universal Joints."
"Relative Efficiency of Four-Wheel Front and Rear-Drive of Commercial Vehicles."
"Detachable vs. Demountable Rims—Combination Rim."
"Commercial Vehicle Depreciation."

ROADMAKERS' GATHERING IN COLUMBUS

COLUMBUS, O., Oct. 18—Arrangements are being made to appropriately decorate Columbus upon the occasion of the annual meeting of the American Roadmakers' Association, the Ohio Good Roads Federation, and the Ohio County Commissioners' Association, all of which will meet in Columbus Oct. 26 to 29. The Chamber of Commerce will decorate the electric arches spanning the principal streets, and many business houses will decorate.

Ground has been broken on East Eleventh Avenue for building a stretch of model highway to be constructed by the Robeson Process Company, of Cleveland, from the refuse of paper mills, which is claimed to be excellent for road building. This has been successfully tried in other states, notably northern New York.

PLAN TO USE CRUDE OIL IN ENGINES

Experiments on the utilization of crude or "scalp" oil in internal-combustion motors seem to promise great economy in fuel cost, especially in large power-plant installations. Thomas A. Nevins, president of the Newark (N. J.) Gas Company, is interested in a process for turning this by-product, for which at present there is little market, into a gas of the nature of producer gas. Previous attempts to utilize crude oil in this manner have failed because of the accumulation of tarry residues and soot, which clogged the working parts of the engines in which the gas was used. No details of the new process have been published, but Mr. Nevins' engineers state that a converter of the new type has been successfully used on a motor boat. The fuel expense has been reduced to about one-twelfth that of gasoline.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers. Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manfacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows Building.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 21-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 19-26......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show. D. H. Lewis, Manager.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

FOREIGN

Nov. 12-20.......London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

AMERICAN

Races, Hill Climbs, Etc.

Oct. 23...........San Francisco, Road Race, Automobile Club of California.

Oct. 28-30........Dallas, Texas, Three-Day Track Meet, Dallas Automobile Club.

Oct. 30...........Vanderbilt Cup Race, Long Island Motor Parkway, Motor Cup Holding Company.

Nov. 6-8..........Phoenix, Arizona, Road Race, Maricopa Automobile Club.

Nov. 8-9..........Savannah, Ga., Georgia Highway Reliability Contest to Atlanta, Savannah Automobile Club.

Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.

Nov. 20-21.......New Orleans, Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary.

Nov. 22..........Denver, Col., Start of "Flag to Flag" Reliability Run. G. A. Wahlgreen, Manager.

Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

PALACE SHOW COMPLETES LIST OF EXHIBITORS

FINAL diagrams for the Tenth International Automobile Show which opens New Year's Eve in Grand Central Palace, New York, under management of the American Motor Car Manufacturers' Association, shows 72 makers of leading American cars and 15 importers of foreign cars, with six additional American cars on the waiting list, making a total of 93 makers of automobiles. This is the greatest number of automobile concerns brought together in any show in New York.

Members of the Motor and Accessory Manufacturers, totalling 110, October 22, will draw for space for the Palace affair, and with 104 accessory concerns not affiliated with the M. & A. M. and twelve on the waiting list brings the grand total up to 319 exhibitors in the Palace Show. Following is a list of the motor car exhibitors which have been allotted space in the Palace affair together with the main floor diagram. All American cars on the main floor are composed of members of the A. M. C. M. A. The foreign cars shown on the diagram are members of the Importers' Automobile Salon.

Unitt and Wickes, of New York, the official decorators of the show, have completed their drawings and models of the Trellis Garden or outdoor effect, which is to lighten the interior of the Palace, and the Show Committee are more than delighted with the result of their efforts. One of the most spectacular features of the decoration scheme will be an electric fountain at the end of the main exhibition hall where the heroic statue of "Age Instructing Youth" stood last year.

AMERICAN CARS

Name	Car	Address
American Motor Car Co.	American	Indianapolis, Ind.
American Motor Truck Co.	American Truck	Lockport, N. Y.
Allen-Kingston Motor Car Co.	Allen-Kingston	New York, N. Y.

GARDEN SHOW TO EXCEL ALL PREDECESSORS

MADISON Square Garden, already the abode of nine successive automobile shows, has been forced to yield up its last inch of space to accommodate the tenth annual show under the auspices of the Association of Licensed Automobile Manufacturers. For three years past the pressure has been intense, and each year it was thought that all the space available had been allotted; yet each following year some ingenious engineering has enabled a few feet more to be secured. This year it seems as if the limit must positively have been reached. Still M. L. Downs, the secretary, is being besieged daily for further grants, which he is forced to refuse. The growth and activity of the industry were never so well expressed as by this constant pressure for show space.

As in former years, the scheme of decoration will be uniform. This branch of the show is in charge of W. W. Knowles. Every effort is being made to have the decorations quiet and tasteful, rather than ornate and gaudy; the decorators will strive for elegance and richness, and the fittings will be solid and substantial. The fact will be recognized that, after all, the cars are the show, and that the decorations are really but a frame, which serves its purpose best when it emphasizes the attractions of the exhibits, rather than draws attention away from them. The same policy of having all the furnishings and signs in charge of the managers will be followed.

One unusual feature of the show this year will be a large exhibit of motorcycles. This will be the only one of its kind to be held in New York, and will be several times larger than any previous show of the kind in the metropolis. Those who favor the "lonesome car" will be impressed by the great strides which have been made this year in this branch of the motor vehicle industry. Motor trucks and other commercial vehicles will also be present in great abundance. The managers are endeavoring to make the show not only as large as possible, but also well balanced and representative of the entire industry.

CARRIAGE BUILDERS HAVE AUTOMOBILE HOPES

WASHINGTON, D. C., Oct. 18—The annual convention of the Carriage Builders' National Association began today and will continue throughout the week. The feature of the convention is the exhibition of all sorts of parts and accessories for carriage and auto builders. A tour of Convention hall, where the exhibition is being held, demonstrates very clearly the interweaving of the automobile and vehicle industries. The exhibits of tires and automobile parts and accessories is a very creditable one, albeit it is not so large as that which marked last year's convention in Chicago, when nearly three-quarters of the exhibits included automobile material and parts. The attendance also demonstrates the mutual interests of the motor car and the vehicle trades. It is a well known fact that many manufacturers of carriages are taking up the manufacture of automobiles, and around Convention hall this week the hope was frequently expressed that the relations between representatives of the automobile and those who represent carriage building will become closer and closer in the future. Among the exhibitors who are identified with the automobile trade are the following:

Diamond Rubber Company, Akron, O., has an interesting exhibit, the feature of which is a motor buggy special tire.

A combination internal and side-wire tire for use on motor buggies is a new feature in the exhibit of the B. F. Goodrich Company, Akron. Mr. Murphy and T. D. Brewster are in charge.

A. P. Cleaveland is in charge of the exhibit of the Firestone Tire & Rubber Company, Akron, O. The Firestone side-wire and motor buggy tire is attracting attention.

The exhibit of the Goodyear Tire & Rubber Company is in charge of G. M. Stadelman.

Republic Rubber Company exhibits its regular line, with J. M. Hoffman and F. A. Hastings in charge.

The Kelly-Springfield tire holds the center of the stage at the Consolidated Rubber Company, New York. The company is represented by F. E. Holcomb, F. A. Kissell, H. S. Cox and M. G. Stockbridge.

Kokomo Rubber Company shows a line of tires in charge of D. L. Spraker.

Hartford Rubber Works Company has a complete exhibit.

Timken roller bearings and axles for automobiles are displayed in the booth of the Timken Roller Bearing Company, Canton, O. W. R. Timken, E. B. Lausier and A. N. Bingham are here for the company.

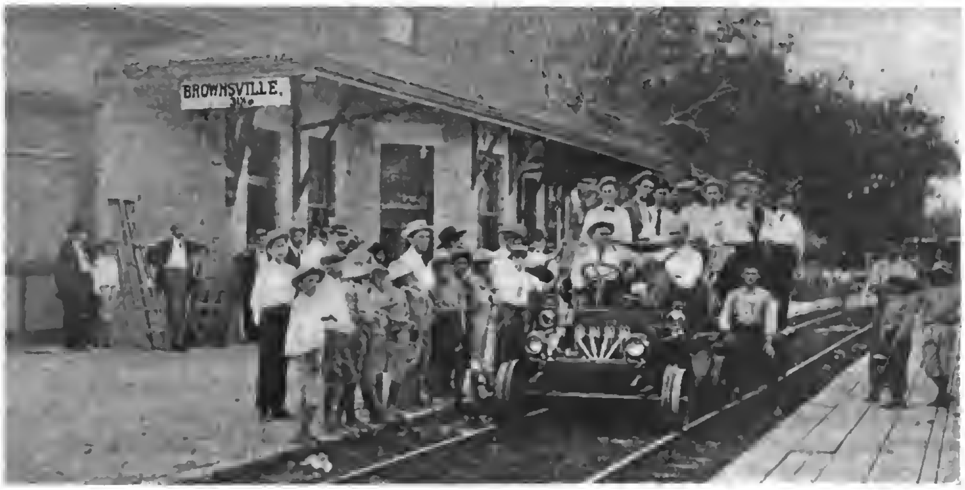
Rose Manufacturing Company, Philadelphia, have a large exhibit of Neverout lamps, with H. C. Rosenbluth in charge.

Other exhibitors well known to the automobile trade include: McKinnon Dash Company, Buffalo, N. Y.; Fairfield Rubber Company, Fairfield, Conn.; Spitzli Manufacturing Company, Utica, N. Y.; Hess Spring & Axle Company, Carthage, O.; C. C. Cowles & Company, New Haven, Conn.; L. C. Chase Company, Boston; Manufacturers' Foundry Company, Waterbury, Conn.; Fabrikoid Company, Newburgh, N. Y.

Besides the exhibition and the exhibits, those present will be entertained by a number of lectures. Among those who will speak or whose topic is of interest to the automobile world are: Second day, Wednesday, October 20, address by B. A. Gramm, Bowling Green, O., "The Evolution of the Motor Vehicle Relative to the Wagon Builder"; third day, address by Hugh Chalmers, Detroit, Mich., "The Principles of Salesmanship."

AUTOMOBILES TAKE TO THE RAILS IN TWO STATES

DELIVERY of mails is of paramount importance, and is not allowed to stop for wind, weather, or other similar obstructions. When reliance is placed upon railroads, and the mails do not materialize, it is then time to take to the automobile, as a sure means of delivery. This was exemplified by an incident in the South recently. The town of Brownsville, Texas, is connected with the world by the St. Louis, Brownsville, and Texas Railway. On the occasion of recent floods in that part of the country, the town was cut off, when the flood washed away a large bridge about forty miles north of Brownsville, and all of the railroad rolling stock was north of the break.



Franklin Fitted with Flanged Wheels Doing Train Service Out of Brownsville

"After waiting four days for mail," says C. Everson, of Brownsville, in describing the plight of the community, "we rigged up a Franklin runabout, fitted flanges to the wheels and operated this end of the road between Brownsville and the bridge.

"The train consisted of two flat cars, on which we hauled passengers and baggage. 'She' gave excellent satisfaction as a railroad engine and made better time than the regular trains over the same road."

In the illustration, the revamped car is shown pulling but one of the flat cars, although the number of men visible would seem to indicate that there were two or even three flat cars behind the sturdy little locomotive, as the Franklin became for the time being. The lack of a bonnet would identify the car anywhere.

PASSENGER SERVICE FOR CALIFORNIA MINING TOWN

MANY small mining towns of the West and Southwest are isolated, and have no regular means of communication with the larger cities nearby. This is particularly the case in the southwestern part of California and Nevada, where the mining towns have sprung up faster than any railroad, no matter how wealthy and well-disposed, could take care of them by building spur tracks from the main line.

One of the smaller mining towns of California, which is so situated is Stone Canon, which is twenty-two miles from Chanslor, itself a small place and situated two miles from Paso Robles. The latter has railroad service, said to be regular, while Chanslor has a sort of apology for service, but Stone Canon, has neither service nor apology, not even a stage line. There was, however, rails laid from Chanslor to the Canon, and Walter Chanslor, of the firm of Chanslor & Lyon, well-known automobile dealers of Los Angeles, conceived the idea of supplying the long-felt want by rigging up a touring car with steel wheels.

This was done and six cast-steel wheels were rigged up to fit a big six-cylinder Premier, which will make regularly scheduled trips between the two towns. Seven passengers will be carried, and for the service afforded, the fare is not excessive.

This service will place Stone Canon on the map and its citizens in communication with the outside world by other means than the laboring burro. When the auto line was proposed by Chanslor, who has large holdings in the town, the residents there were enthusiastic over the proposition and a right of way twenty-two miles long was speedily granted. Long stretches of deep sand intervene between the towns of Paso Robles and Stone Canon. It takes many hours to make the trip by wagon. The motor car will make the trip in an hour or even less.

Premier on Rails Looks Peculiar with Six Wheels as in Service in California

SOME STARTLING INCREASES IN AUTOMOBILE EXPORTS

IN the summary of the detailed imports and exports for the month of August, and the eight months ending with August, the Department of Commerce and Labor shows that the exports in several directions have taken a wonderful upward turn. Such items as a 400 per cent increase in our exports to France, coupled with a 10.3 per cent decrease in our imports from that country, are particularly gratifying to all who have the best interests of the automobile business at heart.

Imports totaled 194 cars, valued at $333,900, being an increase in the number of 8.4 and in the value of 18.8, showing that the average value is on the increase. These were divided as follows:

France......	109 cars valued at	$188,696,	an average of $1,730
Italy.........	52 cars valued at	83,511,	an average of 1,810
Germany....	9 cars valued at	20,589,	an average of 2,280
United K....	7 cars valued at	16,224,	an average of 2,030
All others....	16 cars valued at	24,940,	an average of 1,860

The parts imported amounted to $114,973, as against $49,676 for the similar part of last year. This gave a total value to the imports of $548,874, which the export figures of $658,556 easily surpassed. The latter were divided into parts, $100,622, and the rest complete cars. The cars show a wide diversity of distribution, being allotted as follows:

Country	Amount	Change in Per Cent
British N. America................	$306,523	+76.5
United Kingdom	103,880	—17.5
France	78,693	+406.0
British Australasia	30,969	+142.0
South America	30,256	+379.0
West Indies and Bermuda.........	28,198	+366.0
Other Parts Europe...............	23,205	+380.0
Mexico	21,564	+37.0
Asia and Oceana..................	14,416	+37.7
Germany	11,923	—17.8

Unusual describes the margin of difference in the majority of cases, as shown in the table above.

MASSACHUSETTS HAS A ROAD CENSUS

BOSTON, Oct. 18—Another census of road traffic throughout Massachusetts was taken last week by the Massachusetts Highway Commission, the Metropolitan Park Commission, Boston Park Commission, and Newton Highway Commissioner. There were established about 250 stations, and at all of these a strict count of all passing vehicles was kept for fourteen hours each day, the count beginning at 7 o'clock last Sunday morning and ending at 9 o'clock Saturday night. The arrangements for the census were practically identical with those for the census that was taken in August and which showed that 42 per cent of the total traffic was motor driven. The majority of the counting stations were on the State roads, only a few being established by the other bodies that assisted the Highway Commission.

The August census was taken purposely at a time when the traffic over the State roads was abnormal, but this week's census is expected to show the relative amounts of traffic in its normal condition. The Highway Commission does not expect to see so large a percentage of motor vehicle traffic as in the August census. The count was kept of light and heavy one-horse vehicles, light and heavy vehicles with two or more horses, automobile runabouts and automobile touring cars, and as the time of the count and the stations are identical, it will be possible to make some interesting comparisons with the August results.

OFFER OF FREE ROAD TURNED DOWN

HARTFORD, CONN., Oct. 11—The daily press is asking for an explanation of the refusal of the State Highway Commissioners to allow Morton F. Plant to construct a road through East Lyme and Old Lyme at his own expense. Automobilists, especially, can see no reason why an offer to construct $30,000 worth of macadam and tar road, absolutely free to the State, should have been turned down. There is still a lot of room for road improvement, and every little bit helps. So far the commissioners have refused to make any explanation of their position.

This is all the more inexplainable, when it is considered that the roads of the State are far from being perfect, and each new good road is not only useful, but spurs on other districts.

9,342 AUTOS REGISTERED IN WISCONSIN

MADISON, WIS., Oct. 16—According to figures published by Secretary of State James A. Frear, there are 9,342 automobiles registered in Wisconsin. Of these 40 per cent. are owned in Milwaukee County, amounting to some 3,800 machines. The automobiles in the State represent an investment of $11,677,500. It is said that about one-seventh of these belong to farmers.

ARRANGEMENTS FOR 1910 REGISTRY

BOSTON, Oct. 18—The Massachusetts Highway Commission has just signed a contract for number plates to be used in registering cars next year. The new motor vehicle law becomes effective then, but by a special provision the commission is permitted to prepare the registration and licensing blanks, plates and the like, so that they can be distributed to applicants, beginning the first of next December. This is so that on the first of January, when the new law as a whole goes into effect, everybody will be equipped with their licenses, registration certificates and plates. The contract that has been signed is for 52,790 number plates. Of this number there are 24,000 pairs for private vehicles, 475 sets for manufacturers and dealers and 20 pairs for use on the motor vehicles of foreign diplomatic representatives who may be in Massachusetts. The contract price is about $6,900. The 1910 plate will be of the same design as that used this year except that the colors will be reversed.

No decision has yet been reached by the commission as to the manner in which it will determine the horsepower of motors for purposes of assessing the graded registration fees.

Up to October 1 the State had received this year in fees for automobile registrations and licenses a total of $158,629.52, which is $43,872.52 more than for the same period last year. There had been registered 22,804 automobiles, 7,570 private operators' licenses had been issued and 8,514 licenses for chauffeurs.

FIRST AUTO SHOW IN SALT LAKE CITY

SALT LAKE CITY, UTAH, Oct. 16—The first automobile show to be held in this part of the country will open in this city Nov. 3 for a ten days' run. It will be held in the two main buildings of the Utah State fair grounds. An elaborate scheme of decoration has been prepared. Circulars with floor plans have been sent to the prominent manufacturers, and judging from the replies received, the floor space will be well filled. Rupert Fritz is president and general manager of the show.

TIME AND PLACE SET FOR BUFFALO SHOW

BUFFALO, N. Y., Oct. 18—Instead of the usual location for the automobile show, Convention Hall, the Automobile Club of Buffalo has selected the Broadway Arsenal as the place for its eighth annual show, which will take place February 14 to 19, 1910. The show will be under the highly-successful management of Dai H. Lewis, as in previous years. Mr. Lewis will also manage for the Buffalo Launch Club the third annual Power Boat and Sportsmen's Show. The latter will be staged at Convention Hall, during the week of March 19 to 26, 1910.

What the Clubs Are Doing These Days

LOUISVILLE CLUB'S CLOSELY CONTESTED RUN

LOUISVILLE, KY., Oct. 16—The endurance and economy contest held by the Louisville Automobile Club ended in what threatened to be a tie between the Ramblers driven by Prince Wells and Harry Ropke. Both had perfect road scores, but the technical committee finally penalized Ropke two-tenths of a point for a loose lamp door, leaving the *Herald* cup to Wells. The Cadillac entered by Ira Bennett won the cup offered to the most economical car, having a low score for oil, water and gasoline. Mrs. Harvey Myers, of Covington, Ky., the only woman driver in the tour, won the prize for using the least water for her Buick, and R. E. Gregory's Cadillac burned the least oil. The Standard Oil Company's booby prizes were won by Harry Ropke and Mrs. Myers for consuming the most gasoline; by Mrs. Myers and George H. Laib for burning the most oil, and by Mr. Laib for using the most water.

Twenty-seven cars participated in the run. From Louisville the course led through Lexington and Paris to Winchester, 170.2 miles, where the night was spent. The return was via Frankfort and Shelbyville, 197.2 miles. The owners' trophy, a silver cup donated by the Louisville Automobile Club, was won by Rambler No. 11, entered by Bertram H. Straus, the car being judged by both reliability and economy. It lost one-tenth point on the road.

MARYLAND CLUB'S PROGRESSIVE CAMPAIGN

BALTIMORE, Oct. 16—With the election of new officers at the meeting this week the Automobile Club of Maryland started a progressive campaign for the winter months. The officers chosen are C. Howard Milliken, president; Osborne I. Yellott, vice-president; Frank W. Darling, secretary (re-elected), and Thomas Young, treasurer. The board of directors consists of James Stone Reese, Edward S. Dickey, Hugh H. Young, Edward C. Wilson, Joseph M. Zamoiski and Joel Nassauer.

Mr. Yellott announced that the committee on road signs, of which he is chairman, has placed signboards in various parts of Baltimore county, particularly in the neighborhood of Lock Raven. Other signs have been placed in the vicinity of Catonsville and Towson, and within a short time other parts of the county will be posted.

Already show talk is in the air, and, in fact, tentative plans for the second annual exhibition under the auspices of the club have been laid out. The members favor an early show this winter. Many Baltimoreans will attend the Atlanta show, and profit by that exhibition in their plans for the local affair.

VARIED TOURNAMENT OF ONE OHIO CLUB

ASHLAND, O., Oct. 16—The tournament held by the Ashland Automobile Club met with much success. The program showed much ingenuity, embracing several novel events, such as the "hospital race," in which the contestants hit a dummy with their cars, stopped, took the dummy on board and carried it back to the judges. The "teeter board" and the "water race" also gave much amusement. Among the winners were: F. Heitz, Dean Ridgley, H. A. Mowrey, Gene Fritzinger, H. Peters and Dr. Ray Ash. The hill climb, one-third of a mile long. was won by H. B. Ridgley in thirty-four seconds.

PITTSBURGH ELECTION AND SHOW ARRANGEMENTS

PITTSBURGH, Oct. 18—The annual election of the Pittsburgh Automobile Club, which was held last week, resulted in the choice of W. N. Murray for president; Frank Saapt, vice-president; J. K. McKeough, secretary, and G. P. Moore, treasurer. The club is starting arrangements for a third automobile show.

NO CLUB RUN TO VANDERBILT FROM HARTFORD

HARTFORD, CONN., Oct. 16—At the meeting of the Automobile Club of Hartford this week it was voted not to attend the Vanderbilt Cup race in a body. Last year the club conducted a successful run to the race, but though assured beforehand of a good parking space, the participants could not see the track on account of the crowds that overran it. However, many of the club members will visit the race this year unattached, and these are already arranging for parking space, in the hope of doing better than last year.

Several new members were elected at the meeting, and the growth of the club in the last six months is regarded as most encouraging. Guy K. Dustin, former secretary of the club, but now resident of New York City, was elected an honorary member, in recognition of his services when in office. Following the regular business meeting, Hiram Percy Maxim gave a talk on his fire-arms muffler and made several demonstrations of the device.

Through the co-operation of the club a hundred elderly people were enabled to attend church service last Sunday, who otherwise would have had to stay at home. For many the "joy ride" was an innovation. Each car carried an escort, and a committee was at the church to care for the old folks on their arrival.

ELECTION TIME FOR MILWAUKEE CLUB, TOO

MILWAUKEE, WIS., Oct. 16—Clarke S. Drake was re-elected president of the Milwaukee Automobile Club at the annual meeting of the directors. Faustian Prince was elected first vice-president; George A. West, second vice-president; Arthur C. Brenkle, secretary, and Lee A. Dearholt, treasurer. James T. Drought was again chosen legal counsel. The club is in excellent financial condition, and will proceed to build its clubhouse, long proposed, in the spring. The club owns three acres of land on Blue Mound Road, which will soon become part of the boulevard designed ultimately to connect Milwaukee and Madison, the state capital. The club will also exercise an option on an adjoining acre. It is expected that the show to be held in the Auditorium next spfing will provide the necessary funds.

MICHICAN ASSOCIATION WILL LOOK TO SIGNBOARDS

DETROIT, Oct. 16—Michigan will no longer be the desolate, signboardless waste of the past if the latest effort of the Michigan State Automobile Association works out as expected. By another summer, it is hoped, travelers will be able to tour over all the main highways in the lower part of the State without fear of going wrong. The executive committee of the association, consisting of President Skae and Messrs. George, Ramsey, Warnshuis and Jackson, is back of the move. The first work will be done on the road leading from Detroit through Grand Rapids to Holland.

BOSTON ENDURANCE RUN INDEFINITELY POSTPONED

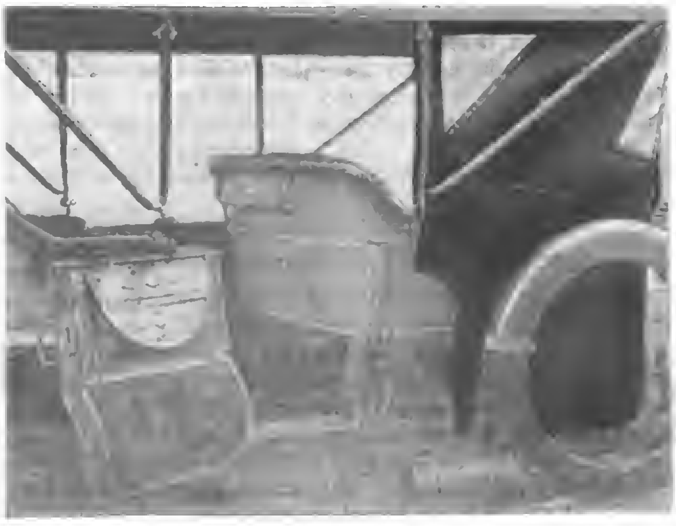
BOSTON, Oct. 18—At a meeting of the contest committee of the Bay State Automobile Association this evening it was decided to postpone the two-day endurance run scheduled for Thursday and Friday of this week. The entries were due to close to-night and only fourteen cars has been nominated. The committee considered this an insufficient number. It was stated that many automobilists had refused to enter because they had not yet secured their 1910 models. The committee will make another canvas of the trade, and if it is assured of a good-sized entry list will select another date for the run. Otherwise the event may be abandoned.

Hanch's Storm Curtains Applied to Marmon Touring Car

NEW TYPE STORM CURTAINS

Anyone who has ever stood out in a pouring rain to put up the storm curtains on his car, getting thoroughly drenched in the process, so that the curtains when put up were useless to him, will appreciate in no ordinary manner the use of a curtain which may be put on from the inside and with as little labor as the other kind. Just as a matter of doing as always has been done, all carriages and automobile curtains fasten on from the outside. A Western man, C. C. Hanch by name, having been through the experience mentioned above with carriages, decided when he purchased his first automobile to have something different.

So he had the top made so as to take inside fasteners for the curtains. This first attempt, as he says, was rather crude, but it showed him that the basic idea was all right. Then, upon the purchase of another and more modern car, a 1910 Marmon "32," he carried out the idea of inside curtains in a satisfactory manner. To quote from his own description: "The top is made with inside curtains, as before, but instead of using the ordinary celluloid storm front, I have employed a standard wind shield for the front and have made the inside curtains to match and fasten to the inside of the frame of the wind shield. The curtains are made in two pieces for each side, and join at the second bow from the front. The appearance and arrangement of the curtains are clearly shown by the annexed cut. In order properly to preserve the curtains when not in use, and still have them instantly accessible, I use a light metal tube, which is fastened with straps back of, and just below, the ledge of the front seat. The location and method of installing the tube are indicated in the second cut. The curtains are rolled and not folded, which helps preserve the celluloid windows, and when placed in the tube they do not take up any toe room and are not in the road in any way. It is only a minute's job for the driver, sitting in the front seat, to open the tonneau door, slip out the curtains and suspend them in position without getting out in either mnd or rain. I am confident that this will appeal to the motor car user who has been 'through the mill.'"



Cylinder Containing Curtains on Running-Board

RESTA WOULD DRIVE IN VANDERBILT

Dario Resta, one of the best known foreign racing drivers, is paying a visit to America, and should opportunity present itself, he would drive a car in the Vanderbilt cup race. Resta has been a successful pilot of the Mercedes on the Brooklands track, and one of his most recent appearances was at the wheel of the Lucas Valveless car, which has been attracting considerable attention recently in England. Any concern seeking a thoroughly first-class driver, would improve its chances by effecting an arrangement with Resta, whose European reputation would add to the international character of the Vanderbilt event.

Baker Electric of "First Lady in the Land"

The accompanying illustration shows a Baker Electric drawn up in front of the White House, at Washington, awaiting its owner —"the first lady in the land." It does not show the Exide battery with which it is equipped, but it is there, and the Baker vehicle with the Exide battery form a combination hard to surpass. It is also noteworthy that the King of Siam has ordered a Baker Electric with Exide batteries for his personal use.

TOLEDO AFTER TIRE PLANT

Toledo, O., Oct. 18—Indications point to Toledo's automobile industry developing rapidly. Since the location of the Overland Automobile Company in this city, two auto parts factories have been added through the direct influence of President J. N. Willys, and he has just announced that there is every reason to believe that a large tire plant will be induced to move its plant here. While definite details have not yet been announced, it is stated that the company considering a change is located in Akron, and that the Overland company is ready to contract for enough tires to insure the company of all the work it can do. The Toledo Chamber of Commerce is interested in the project, and is ready to offer inducements.

New Orleans, La.—The Parlor Stables at Canal and Galvez streets have been leased by the Glide Automobile Company, the agent for the FoFrd and Regal cars. The stables will be entirely remodeled to an up-to-date repair shop, garage, and show room.

Addition to Plant of the Speedwell Motor Car Company, Dayton, O., That Will Be Followed by Another of Similar Size

SOME NEWS FOUND DURING FACTORY VISITS

Brush Runabout Company, Detroit—The new plant of the company is shaping up and the parts of the new models are being made up at the plant of the Briscoe Manufacturing Company in the meantime. Everything is going along nicely; the 1910 car is on the road and it is attracting notice and commendation. The new balance scheme makes the single cylinder motor as smooth as a four and the power is all that any autoist will want in a runabout for general and utility service. With 10,000 cars passing through the shop in all stages of completion it taxes the skill of great shop managers to keep things from piling up, but the Briscoe plant is tried and true, having turned out automobile products on a large scale for several years.

McCord Manufacturing Company, Detroit—The best illustration of the way this company is going about it is to scan the illustration of the new addition to the already large plant devoted to turning out radiators, force feed lubricators, air propellers and other accessories. The new addition is capable of housing enough machinery to more than double the output and all the product is contracted for on this basis.

Chalmers-Detroit Motor Company, Detroit, Mich.—This company is now finishing its third large concrete building, and many other preparations are being made to put out this well-known line of cars on a basis as never before. H. E. Coffin, chief engineer, despite the load he has to shoulder in order to meet the wants of Chalmers-Detroit dealers, showed THE AUTOMOBILE man all there was to be seen, including two bears that wax and grow fat in a cage in the yard, depicting general prosperity at the plant.

Cadillac Motor Car Company, Detroit—Under the guiding hand of the veteran maker of automobiles, H. M. Leland, Cadillac cars for 1910 are being rapidly completed despite any appearance of haste in the well-equipped plant of the company. Everywhere in the vast plant materials are being whipped into shape, and the fine array of plans, patterns, templates, gauges, and other special equipment available, spells result. Readers of THE AUTOMOBILE may be interested to know that the plant of this company has over 90,000 special gigs, gauges, etc., which are used in the process of building automobiles, and they eliminate the personal equation.

Speedwell Motor Car Company, Dayton, O.—Another saw-tooth factory building has been added to the already large plant of the Speedwell people. This building is of brick and steel, with cement floor, and will be occupied by the upholstering and painting departments, which in the past have been sorely cramped for room. The greatly increased Speedwell output for 1910 is being rapidly pushed forward, and another building equal in size to the one shown in the illustration has been contracted for and will be erected at once.

Hupp Motor Car Company, Detroit—In the new plant of the company, cars are being put together rapidly and the staff is all agog with excitement as the natural outcome of moving into a new plant and building cars at the same time. The little car is becoming a more conspicuous feature in the streets of Detroit every day, and standing in front of the plant for a single hour any day in the week is enough to convince anyone that the cars are being rolled out.

Metzger Manufacturing Company, Detroit, Mich.—This new company, holding in its personnel Messrs. Everitt, Metzger and Kelley, formerly of the E. M. F., is pushing to the fore with the new model, and beyond being busy there is little to be said at the moment excepting that they are making order out of chaos and shaping things for business on a large scale.

Studebaker (E. M. F.) Company, Detroit—Studebaker-Flanders efforts are in the direction of the control of everything that goes to make complete automobiles on a large scale, and anyone who may have given the matter a little attention will readily see that it is a wise man who knows where to get parts these days. As it is, the company has plants either in operation or being whipped into shape to build everything required to make automobiles on a previously un-

New Building That Has Been Added to the Radiator-Making Plant of the McCord Manufacturing Company, Detroit heard of scale, without having to say "by your leave" to any one.

Demotcar Company, Detroit—A newcomer, with 3,000 cars projected, to be marketed at $550, is making a lot of talk. Dealers are flocking to Detroit from Texas, Oregon and Maine to have a look and the promoters of this popular priced car are playing "center rush" in a swift game.

Clark-Carter Automobile Company, Jackson, Mich.—This is a recent one, with ample capital and a well appearing model. The company has purchased the Eber L. Peek property, with its 20,000 feet of floor space, as a nucleus. The Cutting Motor Company, of Newark, N. J., will market the cars, and the first model, now on wheels, is known as the Cutting "40," and will sell at $1,600.

Rapid Motor Vehicle Company, Pontiac, Mich.—This concern will have something important to say to the users of commercials this year. Things are shaping up at the plant, and besides a small model for light delivery work the three-ton truck will probably be a feature of 1910. It is a good deal of a job to prepare the line for announcement, and at the present time all that can be said is that Rapid trucks are to be up to a fitting standard.

Oakland Motor Car Company, Pontiac, Mich.—With materials coming in from many quarters, and models ready to be duplicated by the thousand, this company is making rapid strides toward an addition to the original plant, which will increase the capacity several times. When THE AUTOMOBILE man called recently one of the large additions, about 60 x 300 feet, four stories high, was under contract to be finished within 15 days after the contractor started to raze the old wooden buildings that clogged the wheels of progress. The buildings are all to be substantial brick affairs and the showing made in five days is evidence of the fact that the contractor will lift the premium. The old Oakland plant is revamped, new hardwood floors are down, and all the plants in the vicinity are absorbed. Jesse Eccleston, representing the sales department of the Oakland, is energizing the situation, and Oakland models, as fast as they come from the shop, are given a critical eye. Automobile Engineer Brush is putting his best licks on the new Oakland $1,000 car. It is swung right, looks well and has speed.

Inter-State Automobile Company, Muncie, Ind.—Owing to increased demands for Inter-State cars, the Inter-State Automobile Company has now under course of construction an immense addition to its already large plant. The three floors of the new building are 430 feet long and 66 feet wide, which includes a spur running out from one end of the building. Its total floor space will be 85,000 square feet, which added to the old plant will make a total of over 150,000 square feet of floor space. The capacity and output has been increased to five times the number of cars manufactured in 1909 and the company expects to manufacture 2,500 cars for 1910. A spur track will run the entire length on the outside of the building and a large shipping platform will be made for handling shipments without delay. The steel work shown in the illustration was erected in less than two weeks and the same general fireproof construction will be used as used in the other buildings. This is an all steel and window construction on the sides with steel frames and window and brick construction on the ends. This will furnish the maximum amount of light, and since this building will be devoted to painting, upholstering, finishing and final assembly it will be particularly adaptable for the work. All the departments mentioned will be removed to the new building in plenty of time to get well equipped to handle the 1910 models to better advantage than formerly.

PROMINENT HOOSIERS ORGANIZE

INDIANAPOLIS, Oct. 18—An imposing group of business men and mechanical engineers forms the Indiana Motor & Mfg. Co., which was incorporated last Saturday. State Auditor John C. Billheimer has been elected president, and Don J. Hayden, a former newspaper man, secretary. The general manager will be Charles B. Riley, until recently secretary of the State Railroad Commission, and John E. Matson, former superintendent of the American Gera Company, will have a similar position in the new concern. Others interested are Charles A. Denby, former U. S. Minister to China; W. F. Crawford, James S. Cruse, Henry C. Thornton, R. A. Lemcke and Claudius C. Jones, all prominent men.

The company has leased the former plant of the American Harness & Leather Company, at Franklin, Ind. General offices will be maintained in Indianapolis. A four-cylinder, 35-horsepower touring car will be the first offering of the company.

RECENT TRADE PUBLICATIONS

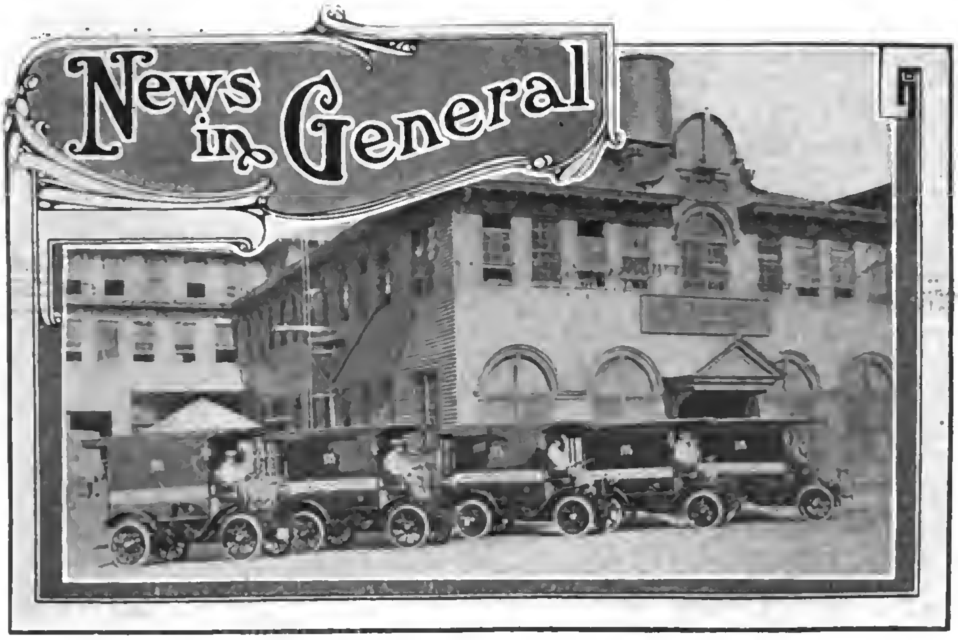
Diamond Rubber Company, Akron, O.—Two neat catalogs of medium size have arrived from the office of this well-known tire manufacturer, one devoted to solid tires for motor buggies and the other to tires for commercial vehicles. The former describes four types of tires, distinguished by their retaining devices: the internal wire, side wire, combination internal and side wire, and clincher. The rims for the first three are of channel shape and are interchangeable; but the clincher type naturally requires a different design. The names of the different types are alone almost sufficient to describe them. The internal wire has two circumferential wires imbedded in the rubber; the side wire has two circumferential wires resting on the ends of short cross wires, and the combination has four long wires as well as the cross ones. The clincher type is made under the Swinehart patent, and is of the familiar grooved shape. The catalog gives all the information necessary to order the tires, and also describes and lists the machines for applying them to the rims.

The commercial car catalog describes the new wire mesh base type, as well as the side wire. The wire mesh base tire is built up on three layers of heavy woven wire, giving it great strength, and is secured to the rim by a circular flange clamped by bolts piercing the rim. The flange is a simple flat ring of steel, and the construction is in every way the simplest and strongest conceivable. This type, as well as the side wire, is made double for extra heavy service. The stock sizes run up to 42 by 7-inch single and 42 by 5-inch double. The catalogs are good examples of printing, and are clear and concise in description.

The Waverley Company, Indianapolis—Green and gray forms the prevailing color scheme of a handsome catalog devoted to the 1910 Waverley Electric. The cover bears an embossed design of a Waverley car against a background of an Italian garden in green, with the name "Waverley" in gilt. Paper and presswork reach the high standard now expected of all catalogs, even those of the most utilitarian articles. The only important change in the mechanism of the Waverley models seems to be the new driving system. The motor and the gears giving the first reduction are carried on the body frame, their shafts lying transversely to the car. From the gear of the first reduction a short, universally jointed propeller shaft runs parallel to the rear axle to the pinion of the second gear reduction, which meshes with a gear mounted on the differential. As the second gears are placed just inside the seat of the left rear spring, the shaft runs nearly the whole width of the car between the spring seats. The movements of the motor due to spring action are thus taken up with comparatively little angularity of the universal joints. In the body design of the Waverleys, stress is laid on the drop frame, which allows the underbody of the machine to carry out the graceful curved lines of the upper work. This frame is used on the brougham, coupe and victoria models. The line is completed by a light runabout, a stanhope, a surrey and a roadster.

Winton Motor Carriage Company, Cleveland—One of the most artistic booklets that has appeared in automobile circles is the 1910 Winton catalog. It hardly seems fair to call it a catalog, as anyone who did not know that "Winton" was the name of an automobile (if any such person can exist) would at first glance take it for a Christmas edition of a popular novelette. It is bound in stiff covers of marble-tinted paper, and the reading matter is printed on heavy glazed stock, profusely illustrated with half-tones. The four full-page pictures of the 1910 Winton "Six" are particularly striking, as the figures of the car stand out boldly on shadow backgrounds of rural landscapes, showing in the distance an attractive country house or bungalow. The car itself, which differs only in the most minor details from the 1909 model, is thoroughly described, and much space is given to setting forth the merits of the six-cylinder motor, in which Winton, it will be remembered, is an enthusiastic believer.

Framework of New Addition to Inter-State Automobile Co., Muncie, Ind.



Autocar Trucks for Philadelphia's Post Office Service

The five trucks pictured above have just been purchased from the makers, the Autocar Company, Ardmore, Pa., by the United States Government, and will be placed in the Postal Service, for the collection of packages and mail in northern and northeastern sections of Philadelphia. Starting in October 1st, they replaced ten horse-drawn vehicles.

Upkeep of Hudson Runabout—The San Francisco agent of the Hudson Motor Car Company recently sent in a statement of the upkeep expense of his demonstrator, which illustrates the economical running of modern light cars. Between August 1 and September 30 this car was driven 3,634 miles, both by the dealer himself and by prospective customers; during this time a record was kept of the gasoline and oil consumed and of the time spent on the car by employees. The total bill amounted to $52.50, about 1.4 cents per mile. Not one cent was charged for mechanical repairs, and only 75 cents for tire repairs. Storage, of course, was not included. This is the more remarkable when it is considered that for a considerable part of the mileage the car was in the hands of persons more or less inexperienced in its operation.

Reminder of the Oil-Can—Insufficient lubrication is a dangerous thing in an automobile, and perhaps has cost careless owners more money than any other one cause. The engine, gears and axles are almost always lubricated automatically by reliable systems, but there are many parts where no means has been found of dispensing with the humble but useful oil-can. For the benefit of those who are wont to neglect its use, the Pierce-Arrow Company has originated a neat reminder. It takes the shape of a printed chart of instructions, which is pasted to the board under the driver's seat and glazed with material that will withstand any rough usage. The driver cannot lift the cushion of his seat without finding the reminder staring him in the face, and it is always there should the regular instruction book be mislaid.

"Exide" Tells Its Story, and More—The Electric Storage Battery Company, of Philadelphia, has issued an attractive publication on the "Exide Sparking Battery." It contains a very complete description of the company's well-known ignition cell and a rather unusual double-page illustration showing its entire construction at a glance. Every feature which makes this battery durable and efficient is clearly shown. In addition to this description of the battery three timely articles have been specially written for this publication by the editors of The Automobile, *Motor*, and *Cycle and Automobile Trade Journal*. The booklet is well worth preserving, as the articles touch upon such subjects as spark plugs, care of the automobile, etc.

Goodrich in Reliability Runs—Twenty-one cars in the recent endurance run at Kansas City were fitted with Goodrich tires, and the Franklin car which won the trophy was among this number. The tires on this car had covered four thousand miles before the run and yet went through the strenuous trip without a puncture. During the 900-mile tour not a single Goodrich tire was taken from its rim. The Elmore, winner of the Munsey tour, also was shod with Goodrichs. During the run of 1,600 miles these tires had but a single puncture; this, too, in spite of the fact that they had been used several thousand miles before the tour.

Rapid Transit in Jersey—Articles of incorporation have been filed by the Suburban Motor Transit Company, with a capital stock of $100,000. Among those interested are Edwin M. Simpson and former Senator R. F. Pettigrew, of New York City; G. H. Atkinson, C. H. Winans and others. J. A. McClary has been made manager and will make his headquarters in Rahway. The company is to operate an automobile line between Elizabeth and South Amboy in place of the proposed trolley line, which had to be abandoned. Four automobiles will be operated and the company may extend into the taxicab line.

Franklin Freight Shipments—During the year ending September 1 no less than 864 freight cars were loaded with automobiles and shipped from the factory of the H. H. Franklin Mfg. Co. The freight charges totaled $67,000. The automobile shipments had a total weight of 3,668 tons. Shipments other than those of automobiles numbered 26,518. Incoming freight cars reached the figure of 598. Merchandise inbound aggregated 10,411 tons and outbound, 5,163 tons.

Aeronaut Curtiss Also Becomes Autoist Curtiss—Glenn H. Curtiss, the well-known aeronaut, has succumbed to the blandishments of a Chalmers-Detroit runabout, possibly due to his association in Paris with R. D. Chapin, the general manager of the Chalmers-Detroit Motor Company. Recently Mr. Curtiss visited Detroit as the guest of Mr. Chapin and incidentally surcharged not a few autoists with aeroplaning enthusiasm.

New Maker of Auto Axles—The Russel Motor Axle Company was recently organized in Detroit with a capital of $100,000 to manufacture automobile axles on a large scale. The new company is an outgrowth of the Russel Wheel & Foundry Company, one of the largest of local structural steel makers. It has purchased the plant of the Wagner Tool Works and is putting in a complete equipment of machinery.

Salisbury Will Not Move—The Salisbury Wheel and Mfg. Co., of Jamestown, N. Y., denies the report that it is about to move to Peru, Ind. A company known as the Peru Auto Parts Mfg. Co. has been organized in the latter city, and S. H. Penfield, general manager of the Salisbury Company, is to be its president. This fact probably was the cause of the rumor.

Coppock Trucks Reorganized—Fort Wayne, Ind., has been disappointed in its ambition to become the home of an automobile truck factory. The Coppock Motor Car Company, which was considering a transfer to that city, has been reorganized by capitalists of its present location and will henceforth be known as the Decatur Motor Car Company.

Californians Like Racing—The Los Angeles Motor Racing Association has leased for a term of years Ascot Park, one of the best equipped mile tracks in the country, and is planning alterations. The Warner Instrument Company has been requested to arrange, if possible, to time future races on this track with its automatic timing instrument.

Marylanders Hold a Race—The last day of the Cumberland, Md., Fair was signalized by a five-mile match race between the Huffman Automobile Company's Maxwell 30 and the W. W. Garage's Chalmers-Detroit 30, on the half-mile fair grounds track. The Maxwell won in 8:03 3-4. The race was the first one held in the county.

IN AND ABOUT THE AGENCIES

Regal Will Have Boston Branch—A company has been formed to handle in New England the product of the Regal Motor Car Company of Detroit, Mich. The garage of the Regal Motor Company is being located on Massachusetts avenue and a contract has been signed with the parent concern for 300 cars for 1910. In addition to the cars the Boston concern will carry a large stock of parts and will be the New England depot for the delivery of repair parts to Regal owners. This plan will be of the greatest advantage to Regal owners, of which there are now a great number in New England. The new company is backed by N. C. Griffin and A. W. Mutty. The latter will be the active member of the firm.

Hupmobile and Chase, St. Louis—A new automobile agency has been formed here, known as the General Motor Car Company, to represent the Hupmobile and the Chase commercial cars. The office is at 1120 Third National Bank Building and the garage at 4520 Delmar boulevard.

Grout, New York City—The Imperial Motor Vehicle Company, of 212 West 76th street, New York City, has taken the agency of the Grout car, made by the Grout Automobile Company, of Orange, Mass., for Greater New York and the surrounding territory.

Oldsmobile, Oakland and Brush, Schenectady, N. Y.—H. W. Chubb will distribute the Oldsmobile, Oakland and Brush in Schenectady and vicinity during the coming season. His Olds agency includes Albany, Rensselaer and Schoharie counties.

American and Rapid, Kansas City, Mo.—The Kansas City Rapid Motor and Transportation Company, recently incorporated, has opened quarters at 1420 Woodland avenue and will represent the American and the Rapid truck, as well as the new Westcott.

Cadillac, Cleveland—The Barger Auto Company, Cadillac agent in this city, has leased the entire first floor of the new Skeel Building on Euclid avenue near East Seventeenth street, and will take posesssion soon.

Chalmers-Detroit and Hudson, Schenectady, N. Y.—B. A. Burtiss, of the Burtiss garage, will continue the agency for the Chalmers-Detroit and Hudson and will act as distributor for Eastern New York.

Overland, Brooklyn, N. Y.—C. T. Silver is to act as Brooklyn agent for the Overland, with entire control in both Kings and Queens counties. He will shortly open salesrooms at 62 Flatbush avenue.

Oldsmobile, Utica, N. Y.—Harry A. Davis and Whitney A. Clark have formed a partnership and will represent the Oldsmobile in Oneida and Herkimer counties. Their salesroom is at 12 West street.

White, Toledo, O.—In the future the business of the White Company in this city will be looked after bv the Wood-Kessler Automobile Company, which will devote its exclusive attention to this line.

Chase Truck, Kansas City, Mo.—The Western Commercial Car Company has opened a salesroom and garage at 911 East Fifteenth street and will act as agent for the Chase auto truck.

Ford, Brooklyn, N. Y.—Bishop, McCormick & Bishop, Inc., have contracted to represent the ford in all Long Island, with the standing of a factory branch. They will appoint sub-agencies.

Winton and Rauch & Lang, Atlanta, Ga.—Herrmann J. Haas, the local representative of the Winton and Rauch & Lang electric, is occupying new quarters in the Masonic Temple.

Oakland, Philadelphia—Fred Vanderhoff, formerly connected with the Ford and Bergdoll companies, has taken the agency for the Oakland and will locate on a salesroom soon.

Fal-Car and Woods, Atlanta, Ga.—The Jackson-Cerf Motor Company has been formed to handle the Fal-Car and the Woods electric, with a temporary office at 12 Whitehall street.

Haynes and Matheson, Atlanta, Ga.—The Corker Motor Car Company has opened a salesroom at Fairlie and James streets, where it will show the Haynes and Matheson cars.

Lozier, Kansas City, Mo.—The E. R. Hunnewell Motor Car Company, of 3816 Main street, has contracted for the representation of the Lozier during the coming season.

Haynes and Detroit, Denver—The Krebs-Covington Company has opened a salesroom at 1620 Broadway and will represent the Haynes and Detroit electric.

Rider-Lewis, Birmingham, Ala.—James J. O'Toole, sales manager of the Rider-Lewis Company, has placed the agency for his car with T. S. Smith & Sons.

Baker, Kansas City, Mo.—The Flack Automobile Company will henceforth act as agent for the Baker electric, at its salesroom at 3816 Main street.

Empire, Boston.—The S. M. Supplies Company, of Lincoln street, has taken the agency in this city for the new Empire runabout.

Cadillac, St. Louis—The Bagnell Company, local agent for the Cadillac, has removed to its new salesroom at 4160 Olive street.

PERSONAL TRADE MENTION

Ezra Kirk Rejoins Rainier—Ezra E. Kirk has resumed his former position with the Rainier Motor Company as Western manager of sales. Mr. Kirk is one of the hest-known automobile men in America, having been identified with the industry from its infancy as a manufacturer and later in various executive capacities. He was maker of the Yale car, which was put out by the Kirk Bicycle Company, of which he was one of the owners. He later became sales manager for the E. R. Thomas Motor Company, and then factory manager for the Rainier Motor Company. Recently he was Western manager of the Herreshoff Motor Company, terminating that connection to resume his place with the Rainier. The Rainier Motor Company anticipates marketing 500 big cars during the season of 1910, and 200 of these cars have been assigned to New York; the remainder will be marketed through new agencies now being established in various large cities.

Allen Shelden, president of the Motor Company, Philadelphia agent for the Premier, received a unique tribute last week. Unknown to him, some fifty local Premier owners gathered to banquet him, delegating to H. E. Grant the job of abducting Mr. Shelden for the occasion. The unconscious guest of honor accepted an invitation to ride. While driving leisurely along, Mr. Grant suddenly swerved the car onto the sidewalk and through a hotel door (which had been prepared for the occasion) and landed Mr. Shelden in the midst of the banqueters.

Edward S. Korbel has been appointed press agent of the Tenth National Automobile Show, to be held in Madison Square Garden, New York. Arthur N. Jervis, the former occupant of the position, is now devoting his entire time to the duties of advertising manager of the American Locomotive Company. In view of the fact that Mr. Korbel in the past was Mr. Jervis' assistant, it is assured that the work will be capably handled.

D. E. MacCarthy has sold the controlling interest of the General Mfg. Co., parts makers, of Elkhart, Ind., of which he was president, to A. T. Welles, of Elkhart. Mr. MacCarthy has been connected with the Burroughs Adding Machine Company and the Westinghouse Electric Company. His future plans are unknown, but it is safe to say that he will locate in the automobile industry.

R. S. de Mitkeiwicz, member of the Gas Power section of the A. S. M. E., has become connected with the Alden Sampson Mfg. Co., of Pittsfield, Mass. Mr. de Mitkiewicz will be associated with the New York office, 115 Broadway, as power sales engineer.

"Archie" Hughes and W. J. Foss, who constitute the Foss-Hughes Motor Car Company of Philadelphia, have opened a branch in Newport, R. I. This company also operates branches in Baltimore, Providence, R. I., and Wilmington, Del.

Raymond S. Joo, formerly with the B. F. Goodrich Company in New York, has assumed the management of the New England branch of the Rainier Motor Company, in the Motor Mart, relieving George T. Gould.

George Crittenden, who has been connected with the Whitten-Gilmore Company, of Boston, has joined the sales department of the American Automobile Company, of that city.

Irvin G. Berryman, formerly assistant superintendent of the Simplex Motor Car Company, Mishawaka, Ind., has been promoted to superintendent in place of Mr. Moore, resigned.

H. C. Henderson, for several years connected with the E. R. Thomas Motor Company in Buffalo, N. Y., has joined the selling force of the Boston branch of that company.

G. Hilton Gantert, who represents the Stearns in Philadelphia, has taken the Quaker City agency for the Herring-Curtiss aeroplane.

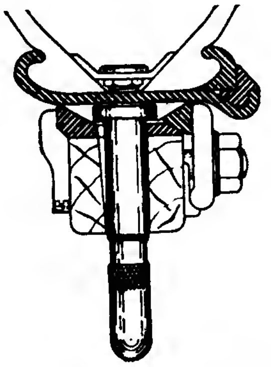
BOSTON TRADESMEN HAVE OUTING

Boston, Oct. 16.—The annual fall dinner and outing of the Boston Automobile Dealers' Association was held Wednesday afternoon and evening at Ferncroft Inn, and in many respects it was the most successful gathering ever held by the organization. More than sixty members and guests were present and most of them took advantage of the glorious autumn afternoon for the run to Ferncroft over the old Newburyport turnpike. At the inn secretary Chester I. Campbell had perfected the arrangements in advance, and about seven o'clock the members sat down to one of the famous chicken dinners for which Ferncroft is famous. At the after-dinner exercises President John H. MacAlman presided, and in his usual vigorous fashion, called upon different members for contributions of speech, song, or story.

Among those who responded were E. A. Gilmore, of the Whitten-Gilmore Co.; C. J. Bailey, J. W. Maguire, of the J. W. Maguire Co.; A. B. Henley, of the Franklin branch; C. P. Rockwell, of the Rambler branch; F. P. O'Brien, of the J. W. Maguire Co.; C. A. Gilmore, of the White Co.; J. W. Bowman, of the J. W. Bowman Co., and members of the press. Among others present were J. S. Hathaway, of the White Co.; George H. Lowe, the veteran of the local automobile trade who has been ill for a year or more and who was given a great ovation; F. E. Wing, of the F. E. Wing Motor Car Co.; S. H. Baker, of the Fiat Branch; V. A. Charles, of the Inter-State and Empire agency; H. L. Johnson, of the Premier Branch; J. H. Johnson, of the Buick branch; Harry S. Howlett, of the United Manufacturers; Howard Limric, of the Goodrich branch; William Gray and A. Hollander, of Gray & Davis; Fred Ayres, of the Fisk Co.; John Cooper, of the Ajax Co.; A. P. Underhill, of the Underhill Co.; F. A. Hinchcliffe, of the Winton branch, and others.

Information for Auto Users

Newest in Demountable Rims—At the Southern show, to he opened in Atlanta, Novemher 6, the first showing of the new demountable rims will be made hy the Firestone Tire & Rubher Company, Akron, O. This new rim works on an entirely new principle and has many commendable features. It may he used with regular quick detachable tires, in fact, its greatest feature lies in its having been designed for this purpose. It may he used the same as any quick detachahle tire after the usual demountahle rim changes have all heen made, and the ex-



SECTION OF FIRESTONE'S NEW RIM

tra supply of demountable rims used up. This is made possihle hy fitting over the regular tire valve a sleeve. This is interposed between the dust cap and the hase of the quick detachable rim, as the cut shows. No locking nut is used, the dust cap on the valve stem serving to hold the spreader in place or release it when the autoist desires to remove his tire and tuhe. During this operation the sleeve remains unchanged in its position in the hole through the felloe. When the rim is demounted in the regular way the sleeve, dust cap, etc., slide through the hole in the felloe. This gives the new rim a double value to the motoring public, in that it may first be used as a demountable rim to the extent of the numher of spare tires owned or carried, in which it possesses all of the many features of a demountahle. Beyond that the second and different feature of using the tire itself and independently of the rim, as a quick detachahle tire comes into use. This douhle purpose rim and tire comhination should meet with instant favor. On account of the trouble and hother with stayholts this concern has practically dropped the exclusive clincher demountable rim, so it announces. At the same show the new tires will also he exhibited. On all of the 1910 tires the thickness of the tread has heen increased.

Alumaloyd, a New Sheet Metal—In seeking a substitute for sheet iron and sheet aluminum for various automobile purposes, each of these possessing some defect, the Spark Rolling Mill Company, Canton, O., hit upon the happy combination of a special analysis rolled sheet steel, with a smooth, velvet-like coating of aluminum. This comhination gives all of the strength and rigidity of the ordinary steel sheet, as well as the admirahle surface and appearance of aluminum. The hig advantage to the hody builder in the use of this metal is that the sheets are ready for instant use, and need not the slow and costly sorting, cleaning, and other preparing actions that the steel does. In the paint shop this metal is a money saver, since its use eliminates sand-papering, filling, rough stuff, putty-glazing and pumice-stoning operations. Each one of these represents an outlay of time as well as money, so that in saving them the total represents quite a large economy. The sheets of Alumaloyd are availahle in all standard U. S. gauges from 16 to 28, and come in four sizes of sheet.

New and Different Tire Mold—Just so long as experts differ on the relative merits of the molded and the wrapped tread processes for manufacturing automohile and other tires, just so long will the Akron-Williams tire mold, made hy the Williams Foundry & Machine Co., Akron, O., enjoy much popularity. The reason for this is because the mold includes the hest features of hoth processes without any of their disadvantages. The cut shows the construction of this mold. It consists of two halves, pierced hy numerous holes, which permit the circulation of steam, and the escape of the water of condensation as well as gases which form. The inner surfaces are corrugated, and against these corrugations is inserted a brass wire gauze. The latter is tightly stretched and is held in place by the circumferential wire soldered to it. It is also held hy the additional steel locking rings. Next to this is a layer of duck or canvas, while the tire heads and side walls are formed hetween the iron side mold and the core. The tread is formed between the fabric and the core,

AKRON-WILLIAMS TIRE MOLD

while the profile of the corrugations forms the desired shape of the exterior of the tire. The hig advantage of this mold is that it gives full mold pressure to the side walls and head of the tire, This mold gives the resulting tire a fabric-like appearance, while actually it is ruhber. Besides a pleasing appearance, this partly roughened surface wears very well.

Very Handy Size of Meter—With the increasing use and appreciation of the value of accurate testing instruments for the ignition current, has come a demand for different sizes of such instruments from those previously made. In response to this demand, or rather, anticipating it, the Hoyt Electrical Instrument Works, Penacock, N. H., has brought out a pocket ammeter. This is shown in the cut and possesses all of the valuahle features of larger and bulkier meters, besides being approximately the size of a

POCKET SIZE HOYT AMMETER

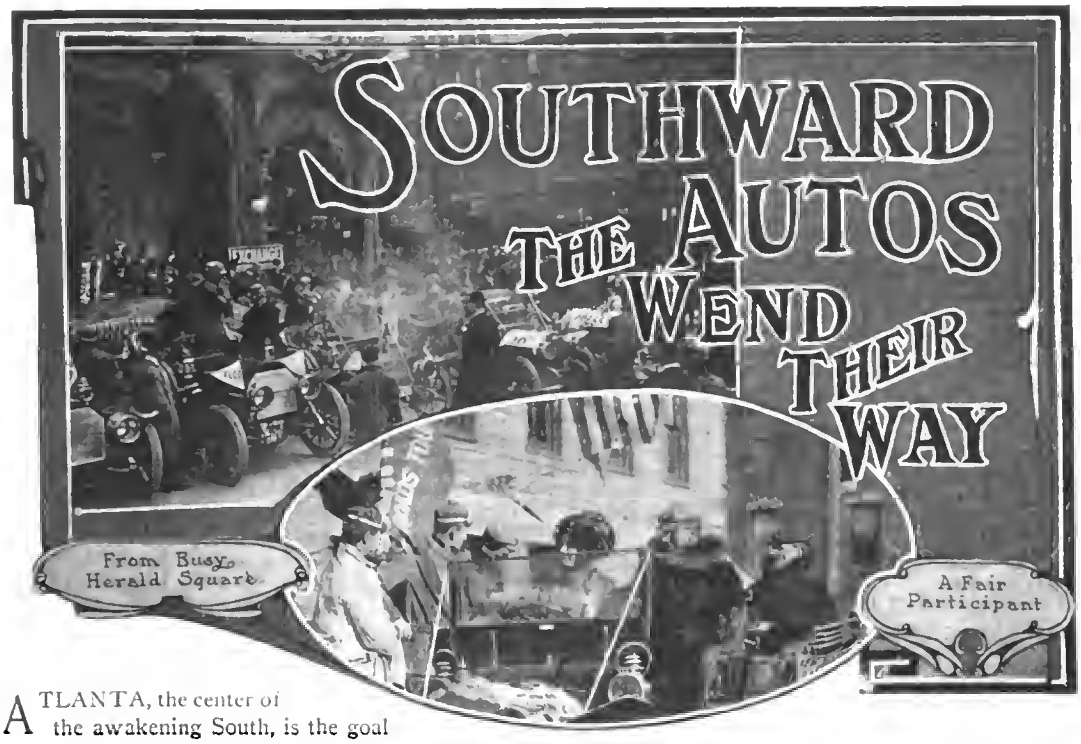
No. 16 gentleman's watch. Since this small and very convenient size will allow of carrying it around in the vest pocket, a large demand for the size is anticipated. Aside from the size, a novel feature of much value is the silver plated metal scale, which comhines accuracy and durahility with tastiness in design. Despite its small size, this meter is made from carefully standardized parts, designed and finished with unusual accuracy. The lettering on the dial has heen changed to make it more legihle, a valuable thing in conjunction with the reduction in size.

New Form of Clutch—There are several inherent disadvantages in each and every form of clutch now in use, which inventors and designers have sought to eliminate but without success. These are large diameter and heavy weight. If the clutch is made small, it must he heavy, and if made large so as to reduce the weight, the rotating force, or inertia, which tends to keep it spinning, is increased in proportion, being dependent upon both the linear speed and weight. A new form of clutch, for which it is claimed that it may be light with very small diameter, is that invented and just put on the market hy W. L. Archer, Burlington, Vt. It is claimed hy the inventor that a rotating memher eight inches in diameter and weighing less than ten pounds all told, will take care of a forty-horse motor without slipping, or seizing. The principle is a combination of an external contracting and an internal expanding band on the same drum, but so arranged that centrifugal force in one is neutralized by that in the other, and that both clutches positively follow the lever, nothing heing left to springs, so that the clutch can be handled without strains, noise, or hother. It is very cheap and simple to build and maintain, is not sensitive to oil or water. The same principle is applicable to hraking effects, in which case the common drum on the rear wheel may be reduced in diameter without sacrifice of braking surfaces.

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, OCTOBER 28, 1909—CHICAGO No. 18

THE AUTOMOBILE



From Busy Herald Square

A Fair Participant

ATLANTA, the center of the awakening South, is the goal of forty-seven automobiles which left New York last Monday, prepared for a ten days' struggle with roads of the best and worst, and all the intermediate varieties. Under the auspices of the New York *Herald* and the Atlanta *Journal*, these pioneers, the advance guard, it is hoped, of many thousands, have undertaken to blaze the touring way between the metropolis of the North and that of the South, enduring what hardships may befall for the sake of the automobilists' watchword, "Good Roads!"

At 9 o'clock of the bright Autumn morning Herald square flaunted bunting and pennants from three-score cars, and a solid line stretched up Sixth avenue in the shadow of the elevated tracks. Then the escorting cars of the New York Automobile Trade Association swept down Broadway, and the waiting column turned into their wake. Not until Fifth avenue was reached did the line reveal its full length; then, freed from the press of traffic, it drew up in close order, still ten blocks long, and charged for the Battery.

Unusual in a tour of this sort, and indicative of the interest and enthusiasm with which the South has taken up the good roads movement, are the many entries by the cities along the route and by their boards of trade or of commerce. Atlanta, Lynchburg, Va.; Charlotte, N. C.; Roanoke, Va.; Moultrie, Ga.; Anderson, Ga.; Spartansburg, S. C.; Winston-Salem, N. C., and Commerce, Ga., all find representation in the line. Georgia, the Carolinas and Virginia will welcome the tourists as forerunners of almost a new era; an era of prosperity and activity, and of free intercourse with the neighboring States.

The tourists include many notables, both of automobiling and other circles. Recipient of a most flattering attention was the great "Ty" Cobb, whose trusty bat has twice helped Detroit to win a pennant. The speedy player, who may now be regarded as one of the automobile fraternity, was at the wheel of the Chalmers-Detroit official car. Frank X. Zirbies, who drove a Mitchell across the continent on a military expedition, headed the line as pacemaker. Many of the cars were gay with Paris millinery and other feminine accessories, for several of the contestants took their entire families with them. One of these parties was that of Jacques Futrelle, the story writer and originator of "The Thinking Machine." Mrs. Joan Cuneo, who has often demonstrated her skill at the steering wheel, brought out her favorite

27 Maxwell, Maxwell-Briscoe Motor Company, Tarrytown, N. Y.
29 White Star, White Star Auto Company, Atlanta, Ga.
43 Chalmers-Detroit, Read Holliday, New York City.
50 Franklin, George H. Storck, Jacksonville, Fla.

CLASS 5—CARS COSTING FROM $851 TO $1,250

18 Maxwell, Automobile and Commercial Ass'ns, Charlotte, N. C.
19 Studebaker, W. J. Stoddard, Atlanta, Ga.
31 Reo, R. M. Owen & Company, New York City.
42 Regal, E. D. Crane & Company, Atlanta, Ga.

CLASS 6—CARS COSTING $850 OR UNDER

28 Maxwell, Maxwell-Briscoe Motor Company, Tarrytown, N. Y.

OFFICIAL CARS (Non-Contesting)

Pacemaker Mitchell, Frank X. Zirbles, Racine, Wis.
Judges' Car, Chalmers-Detroit, A. L. Westgard, New York City.
Official Car, Alco, American Locomotive Company, New York City.
Official Car, Stearns, Wyckoff, Church & Partridge, New York City.
Checkers' Car, Chalmers-Detroit, T. R. Cobb, Detroit, Mich.
Press Car, Rainier, Mrs. Joan N. Cuneo, New York City.
Press Car, Locomobile, Miss Mildred Schwalbach, New York City.
Tire Car, Craig, Ajax-Grieb Rubber Company, New York City.

Although a number of the original entrants had been withdrawn, or failed to appear for various reasons, it was still an imposing procession.

Crossing New York Harbor to Staten Island—The police arrangements had been so admirably planned that the parade made its way downtown with scarcely a check, and drew up at the Battery at half-past ten. Two special ferryboats were in readiness, and on these the tourists were soon embarked. The trip across the harbor was quickly made on the speedy boats. At the St. George, S. I., slips the cars were met by the Richmond County Automobile Club, headed by President Charles A. Schultze, which formed an honorary escort during the brief run across Staten Island, and sped them with best wishes.

Several trips of the ferry at Perth Amboy were necessary to carry the tourists across from Tottenville. Mayor A. Bollschweiler, of Perth Amboy, met the procession at the ferry, and after the ranks had been formed a quick run was made to the Packer House for luncheon.

Through Jersey's Hills and Valleys—At half-past one the tourists were called from their tables, and E. L. Ferguson, of Buffalo, the starter, assisted by the checkers, Mortimer Reeves, of New York City, and Inman Gray, of Atlanta, began sending away the cars at intervals of one minute. New Jersey's hills were glowing in red and brown Autumn foliage, and the crisp air was neither too warm nor too cold for comfortable touring. The cars soon broke ranks, each proceeding at the pace most suitable to its driver, with regard only for the schedule that called for checking in at Philadelphia at a given time.

From Herald Square the Tourists Wended Their Way Southward

Of Course the Perth Amboy Ferry Had a More Than Busy Morning

Near New Brunswick a gang of workmen was found busied in repairing the highway, with a steam roller in full swing crushing down the broken rock. The tourists greeted the sight with cheers, taking it as a good omen that they should so soon meet with a substantial evidence of the progress of the good roads gospel.

Dayton, Cranbury, and Hightstown were traversed in turn, and then Windsor, which proved its loyalty to the cause by displaying a big steam roller busied in resurfacing the macadam. Near Trenton many of the signs which had been posted for the tour had been torn down, partly, it was said, by the town authorities. This unnecessary piece of vandalism caused some confusion among the branching roads just outside the city.

Philadelphia End of First Day's Run—Over the big steel bridge spanning the Delaware River the tourists sped into Pennsylvania, seeking new states to conquer. Active road building operations were in progress near the villages of Trevose and Bustleton. Beyond the latter village, and just on the outskirts of Philadelphia, Pacemaker Zirbies met the scout car of the Quaker City Motor Club. A little further on, near the Widener Memorial school, the police escort provided by the Philadelphia authorities, together with a number of cars of local automobile enthusiasts, awaited the tourists. It was a quarter past four when the vanguard rolled in, and all waited a time to allow the trailers to catch up. Contestants and official cars came dashing in at frequent intervals, and when the line was nearly complete another start was made and the procession swept into the Quaker City, down Broad street to the City Hall.

The checking officials unfurled their standards in front of the quarters of the Quaker City Motor Club, in the Hotel Walton, and were soon busy taking the time of the contestants as each in turn came up. Only two cars failed to appear on schedule, the Oldsmobile, driven by Henry J. Lamar, Jr., of Macon, Ga., and the Pope-Toledo, in charge of Powell Glass, of Lynchburg, Va.

The two delinquents appeared in short order, however. The Oldsmobile driver reported three tire blowouts, for which no time allowance is made under the rules, and in addition a twenty-minute hold-up by a leisurely freight train on a railroad crossing. He received a penalty of twenty-four points. The Virginian escaped with six points marked up against it.

Gettysburg, Pa., Oct. 26—The second day's run of 120 miles ended this evening when the tourists sped into the city that gave its name to the battlefield on which the tide of rebellion was finally turned. Thirty-seven of the thirty-eight contestants arrived on time and without penalty. The thirty-eighth, the Pope-Toledo entered by the Chamber of Commerce of Lynchburg, Va., and driven by Powell Glass, met with mechanical trouble, and was reported to have returned to Philadelphia, thus withdrawing from the tour.

To-day's trip gave additional proofs of the hold the good roads movement has taken on the country. In every city and village the tourists met with an enthusiastic greeting, and the inhabitants showed that they appreciated the purpose of the run, as well as enjoying the holiday for which it gave excuse.

If all the roads on the route to Atlanta were like those which gladdened the autoists for the first hour or two out of Philadelphia, the tour might have disbanded on the spot. Through Ardmore, Bryn Mawr, Villa Nova, Rosemont and other suburbs of the Quaker City, the highways were beautifully smooth, and the cars rolled along their oiled surfaces as if on rails. The Southerners were loud in their praise, one and all asserting that these were the sort of roads they wanted in their own states.

But after Exeter, Pa., had been passed, conditions changed. and the ubiquitous water-break held sway. Progress was by a continuous series of bumps, which would form an admirable subject for a Coney Island side-show. The official Knox car. driven by Joseph W. Jones, with Referee Scarritt as passenger. fell a victim to the extent of a broken spring. The referee was forced to take passage with R. M. Owen, who came by in his Reo most opportunely, and offered his servicees.

All contestants had been warned to look out for police traps

Major John S. Cohen, Managing Editor Atlanta "Journal"

Mitchell Pacemaker With a Notable Cargo

Miss Schwalbach Successfully Copies Late Paris Styles

at Lancaster, Pa., for it was said that the authorities of that town had failed to appreciate the purposes of the tour, and had threatened to have an extra force of constables on duty. No one had any trouble, however, and policemen did not seem unusually numerous.

York, Pa., was the noon stop, ninety miles from Philadelphia. For the rest of the day's trip the roads were of the worst. A heavy toll was called for at the mile-long bridge spanning the Susquehanna, between Columbia and Wrightsville; the fee was forty cents, plus twenty additional for each passenger in excess of four.

Gettysburg turned out en masse to receive the tourists. The town officials took the visitors in tow, and after the cars had been checked in, many made a trip to the battlefield. The contestants and their guests posed for a photograph on Little Round Top, which was one of the most desperately contested points in the historic three-day struggle.

To-morrow's run, from Gettysburg to Staunton, Va., will be the longest of the tour, the distance being 180 miles.

DETROIT MAY HAVE A SPEEDWAY

Detroit, Oct. 25—There is a strong likelihood of Detroit becoming the possessor of a motor speedway similar to that recently put in commission at Indianapolis. Such a project has been talked of for some time, but nothing definite was done. Now it is being revived, and the matter has progressed to a point where two sites are under consideration by those interested in the undertaking. One of these is on the east side and the other in the north end, both easily accessible from all the factories in the city. The plan as outlined is to not devote the speedway to racing events, but have it utilized by manufacturers for testing purposes, each concern participating to pay a proportionate part of the cost. With the rapid increase of the industry and the need of more adequate testing grounds than now exist it is argued that the enterprise could not fail.

"Ty" Cobb, Famous Ball Player, Is Touring Southward

VANDERBILT CUP RACE COMES NEXT

Saturday morning at 9 o'clock the Vanderbilt Cup race will be again contested over the revised and shortened Long Island course. Twenty-six cars will start in the three events: fifteen racing for the cup itself, over 22 laps of the course, four in the Wheatley Hills sweepstakes, over 15 laps, and seven in the Massapequa sweepstakes, going 10 laps. The three races, according to the fashion which is growing in popularity, will be run simultaneously. Preliminary practice, which has been constant for the past week, shows that the predictions made for the course were by no means unfounded. Tuesday morning Bert Dingley, driving his Chalmers-Detroit, set the record for the circuit at 11 minutes flat, a speed for the 12.64 miles of 68.9 miles an hour. The complete entry list follows:

VANDERBILT CUP RACE

Classes 1 and 2—Distance 22 Laps—278.08 Miles

Practice Number	Car	Driver
1	Simplex	L. A. Mitchell
2	Isotta-Fraschini	Joe Seymour
3	Chalmers-Detroit "40"	Bert Dingley
4	Chalmers-Detroit "40"	L. B. Lorimer
5	Fiat	Lewis Strang
6	Alco	Harry F. Grant
7	National	John D. Aitken
8	National	Charles C. Merz
9	Apperson "Jack Rabbit"	Hugh N. Harding
10	American Roadster	Willie Haupt
11	Buick	Louis Chevrolet
12	Fiat	E. A. Hearne
14	Fiat	E. H. Parker
15	Marmon	Harry Stillman
16	Mercedes	S. E. Wishard

WHEATLEY HILLS SWEEPSTAKES

Class 3—Distance 15 Laps—189.60 Miles

31	Moon	Philip Wells
32	Marion	George L. Reiss
33	Marmon	E. A. Harroun
34	Columbia	R. W. Wilcox

MASSAPEQUA SWEEPSTAKES

Class 4—Distance 10 Laps—126.40 Miles

41	Chalmers-Detroit "30"	William Knipper
42	Chalmers-Detroit "30"	Joe Matson
43	Maxwell	Martin Dooly
44	Maxwell	Arthur See
45	Maxwell	Thomas Costello
46	Hudson "Twenty"	George Ainslie
47	Atlas	Elmer Knox

AMERICAN ROAD MAKERS IN SESSION

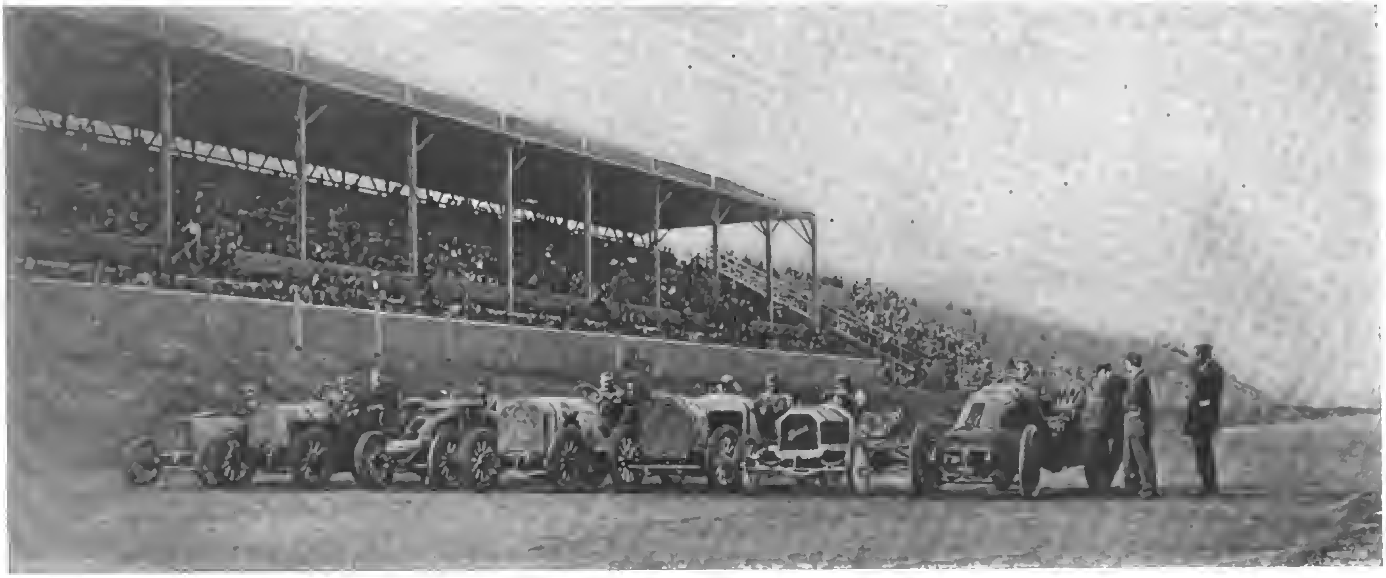
Columbus, O., Oct. 26—Delegates to the number of 900, representing 33 States and territories of the United States. attended the first day's session of the Good Roads Congress, which is a joint meeting of the American Road Makers' Association, the Ohio Good Roads Federation, and the County Commissioners' Association of Ohio. Automobile owners and auto clubs are in evidence in the meeting, but their efforts are only contributory.

Because of the death of a relative, Governor Judson Harmon, of Ohio, did not deliver the welcoming address. His secretary, George L. Long, substituted pleasingly, and was followed by Mayor C. A. Bond, and Secretary J. Y. Bassell of the Chamber of Commerce. The responses were made by James H. MacDonold, president American Road Makers' Association; William M. Hager, president Ohio Good Roads Federation, and O. J. Townsend, secretary of Ohio County Commissioners' Association.

One of the principal addresses of the day was that of Logan Waller Page, director of the office of public roads, U. S. Department of Agriculture, who talked on "The National Government as a Factor in Road Improvement."

Hon. Nahum J. Bachelder, of Concord, N. H., master of the National Grange, discussed the matter of co-operation in road building from the standpoint of the agriculturalist.

The sessions willl continue Wednesday, Thursday, and part of Friday. One of the features of the program for Friday is the opening of the question box in which many interesting matters will be brought up. Automobiles are to be used to transport the delegates to the fair grounds, to view the large exhibit of road building machinery.



First Line-Up of Notable Racing Craft on Atlanta Automobile Speedway, Robertson, Oldfield, and Basle Being Included

ON GEORGIA'S RECORD RACE TRACK

ATLANTA, GA., Oct. 23—The Atlanta automobile speedway has demonstrated that it is ready. At any rate, five miles in 3:52 3-5 looks very much like it. The demonstration was made this afternoon with a few of America's fastest cars and some of America's best drivers here to see that the thing was well done.

In order that the publicity end be properly taken care of, newspaper men were the invited guests of the day, and before the races they were served with a real old Georgia barbecue, with Brunswick stew and some exceedingly "near" beer as a side-line. More than a hundred Georgia newspaper men, along with some Associated Press and United Press notables, were on hand to lend an air of *eclat* to the occasion.

When the cars were put on the track there was no formal program for them to follow. They were merely sent against time, with Fred Wagner behind the stop watch, and no prizes up for broken records. But records were broken, all right. Oldfield, in his 120-horsepower Benz, was the star performer, for he made five miles from a flying start in 3:52 2-5. This is the time as taken: 2 miles, 1:31; 3 miles, 2:21 3-5; 4 miles, 3:03; 5 miles, 3:52 3-5.

The most brilliant performer was Robertson in his 90-horsepower Simplex. He did the five miles in 3:59 4-5. His fractional time was: 2 miles, 1:34 3-5; 5 miles, 3:59 4-5; 6 miles, 4:34 4-5.

Ben Kirschner, under orders not to smash up his Darracq machine, took things easy. His best time was a mile in 53 seconds, which shows the speed possibilities of the track.

A creditable showing was made by Florence Michael, a Georgia driver who goes by the racing name of "Cliquot." This youngster, who never drove a racer before in his life, hooked up wtih the ancient and terrible Pope-Toledo recently acquired by Asa G. Candler, Jr., and christened by him "The Merry Widow," and made good time. Here are the figures: 2 miles, 1:36; 3 miles, 2:45 2-5; 4 miles, 3:38 2-5; 5 miles, 4:34 3-5; 6 miles, 5:21 4-5; 10 miles, 8:42 3-5.

A remarkably good showing was made by Ed. Durant, one of the capitalists who built the track. He drove a stock Renault five miles in 5:08.

Charles Basle was not having much luck wtih either of his Renaults, but for all that managed to reel off two miles in 1:50.

The final event of the afternoon was a three-cornered friendly race, in which Robertson, Michael, and Basle took part. They finished in the order named. Michael, in the Pope-Toledo, led for two miles, but then Robertson made a runaway of it. Basle in his stock Renault was nearly lapped.

POPE-HARTFORD BEST IN PORTOLA RACES

OAKLAND, CAL., Oct. 23—Although somewhat marred by accidents, the races run here to-day were marked by the high average speed maintained and by the walkover in the longer contest, the winning car finishing with a lead of nearly forty miles. Three races were going on at once, all of the cars being started at approximately the same time. More than this the cars of the lowest class were eligible for the other two, and it was the rule rather than the exception that the cars were entered in all three of the races.

Thus the winning Pope-Hartford won the third race also, and only lost the second through the failure to enter in that. The Apperson, which came in second in the longer distance also won at the middle distance, so that each of these cars won two prizes.

The course consisted of a twenty-one mile circuit over dirt roads, but as subsequent events proved, it was very fast.

Cars of a piston displacement of from 231 to 450 cubic inches were elegible for the first race which consisted of seven laps, or approximately 150.5 miles. In the second race, all cars were eligible with piston displacements from 451 to 600 inches. In this class the competition extended over ten laps, making the distance 215 miles. In the big car class, the big race of the day, all competitors covered 12 trips around the circuit, making the total mileage approximately 258 miles. This class was open to cars having a displacement in excess of 600 inches, but smaller engines were not barred.

The times made were fast throughout, a Stearns car, driven by D. A. Bonney, making the fastest lap of the day, 18 minutes and one-fifth seconds, which is in excess of 71 miles per hour.

Of the fifteen starters, about half finished. The big race was won by Fleming in the Pope-Hartford number 4, time 3 hours 58 minutes and 15 seconds, an average of 64.51 miles per hour. Second place was taken by Apperson number 13, driven by Hanschue, two laps behind Fleming. Third place was won by Lozier number 12, with Harry Michener at the wheel, one lap behind the Apperson.

Fleming was also awarded the 7-lap race, the time not being given out. To the Apperson was awarded the 10 lap race, the time for that distance being 3 hours 12 minutes and 33 seconds. The Lozier was given second place in this race.

Several accidents to contestants served to mar the day's sport, thus, A. G. Linz, the machinist of the Maxwell, was painfully injured by the breaking of the flywheel of his motor. Early in the race the Chalmers-Detroit car sustained a broken wheel and Howard Warner, the driver, and his mechanic, James McCauley, were thrown from the machine and badly bruised.

Count De Lambert in His Wright Aeroplane Flying Over the River Orge During the Juvisy Meeting

TWO MEETS START AVIATION PROGRESS IN ENGLAND

LONDON, Oct. 23—Donchester and Blackpool have held rival aviation meets during the past week, each boasting a goodly roll of English and French aeroplanes and aviators. The two towns have been engaged in a rather undignified controversy, each accusing the other of underhand methods in securing contracts, and as a result several of the astute Frenchmen have reaped a golden harvest. The quality of the sport, although not, of course, equal to that at Rheims, has been on the whole very good, and it seems there was room for both.

Doncaster was first away, opening nominally on October 15, but a strong gale kept the aeroplanes in their sheds. The following day Col. S. F. Cody went up about noon in his biplane. After flying about 1,000 yards he miscalculated his distance from the ground on a turn; his front wheel struck, and the machine turned a somersault. Cody was not hurt, but the machine was badly smashed, and was withdrawn for repairs.

In the afternoon the competitions started with an event for five circuits of the course, the distance being five and a half miles. Delagrange, in a Blériot monoplane, was the first to complete the trip, his time being 11 minutues 20½ seconds. Sommer, in a Farman biplane, ascended while Delagrange was still in the air, and for the first time in England two aeroplanes were seen flying together. Sommer completed 9 miles and 1,350 yards in 21 minutes 45 seconds.

On the Field at Juvisy—Indicating that Autoists Are Interested in Aeronautics

The Blackpool meet opened October 18. On the first day Farman led in the speed contest, covering 17 1-2 miles in 23 minutes. Rougier made the longest flight, 22 1-2 miles in 32 minutes. The following Friday Hubert Latham, in his Antoinette monoplane, made one of the most daring flights on record. He went up in the teeth of a thirty-mile gale, twice circling the course. With the wind ahead the machine seemed at times to stand still; but when Latham came about he was driven at terrific speed at least 80 miles an hour. At one time he barely escaped being carried to sea.

A surprising feature of both meets has been the number of English-built machines which have appeared. Although these have not been able to compete successfully with the well-tried French craft and their experienced pilots, they have demonstrated that England is not so far behind in the progress of aviation as might have been supposed. Henry Farman carried off the $10,000 prize for the longest flight and $2,000 for the fastest three laps, and Latham took the prizes for general merit and for the slowest lap.

AMERICA VICTORIOUS IN BALLOON RACE

PARIS, Oct. 20—The Gordon-Bennett cup for spherical balloons was won by Edgar W. Mix, who sailed from Zurich, Switzerland, to a point north of Warsaw, in Russian Poland. His distance is estimated at 680 miles. Alfred Leblanc, the French pilot, was second, with a distance of 520 miles. Mix was arrested by the Russian police on his landing, but was soon released. Owing to a report that he made a landing near Dettva, Hungary, the award of the cup was suspended, but the commission finally decided in his favor. As a result, the race will be held in America next year.

BISHOP RETURNS WITH AERO TROPHIES

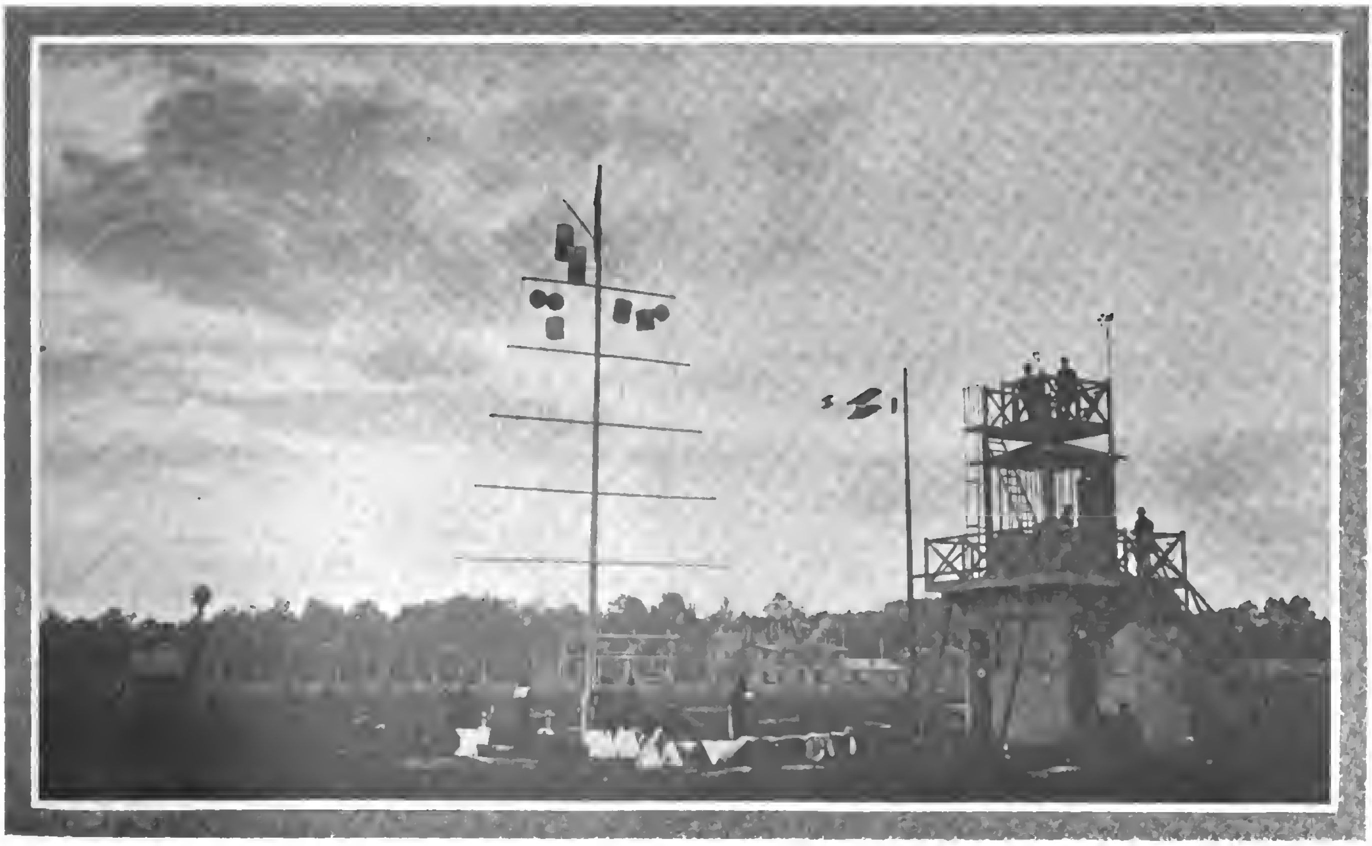
Cortlandt F. Bishop, president of the Aero Club of America, arrived in New York October 24, bringing with him the Gordon Bennett trophy for aeroplanes won by Glenn Curtiss. Mr. Bishop has been abroad for six months, during which he covered 20,000 miles in his automobile, and witnessed all the aviation meets. He was elected vice-president of the International Aero Federation. One of the reasons for his return is the approaching election in the Aero Club of America.

WRIGHT'S MILITARY PUPILS FLY ALONE

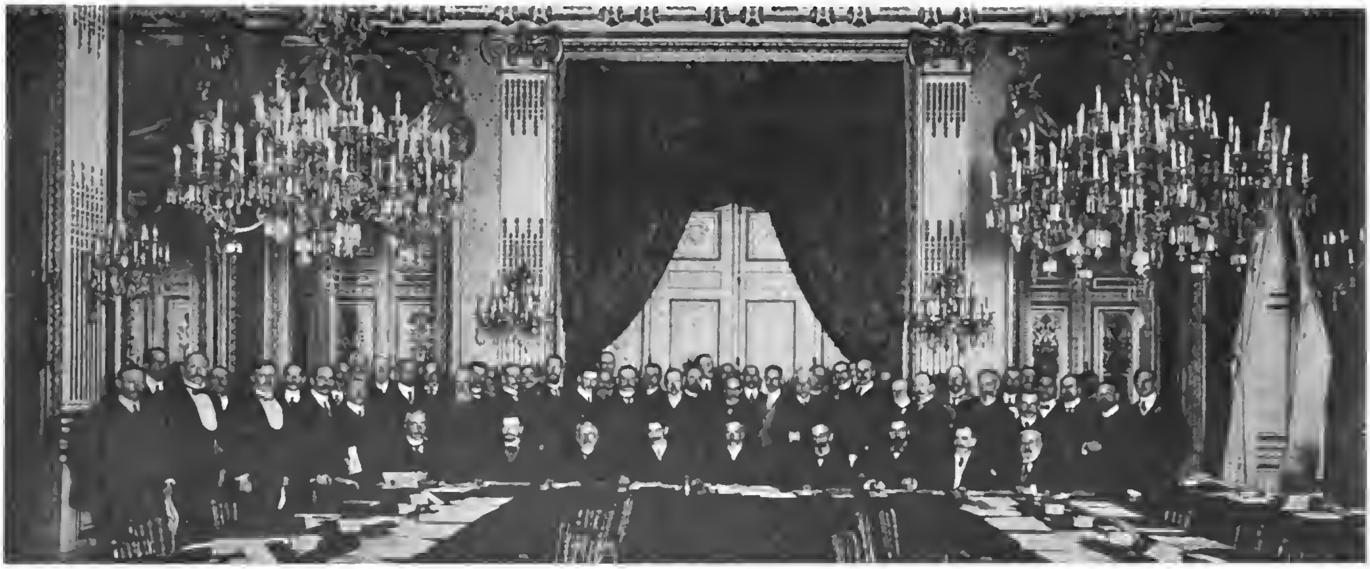
WASHINGTON, D. C., Oct. 26—Wilbur Wright this morning allowed his pupils, Lieuts. Lahm and Humphreys, to ascend alone in the army aeroplane, with which they have been making trial flights at College Park, Md. Lieut. Humphreys went up first, at 8:16. He rose easily and made two circles of the field, alighting easily. Lieut. Lahm, after a false start, got away at 8:41, and circled the field half a dozen times, turning several short circles. He stayed up thirteen minutees. Then Lieut. Humphreys tried again. He, too, made a false start, but ascended at 9:22 and remained in the air eight minutes, equaling his comrade's total time. Finally, Professor Wright took the levers and gave a short exhibition. He cut off the motor while at a considerable distance from the ground, and glided down gently.

President Bishop and Winner Mix at Aero Club de France

The training of the two officers, which has been in progress for nearly three weeks, is now practically completed. Hitherto Mr. Wright has always accompanied his pupils, although often allowing them to hold the levers. Five flights were made October 8. The following day Mr. Wright, alone, made a record of 58 3-5 seconds for a kilometer flight in a closed circuit. Most of his ascensions were made without the starting apparatus.



Fortnight of Aviation at Juvisy—How Aeronautical Contests Are Conducted—Timers' Box and Signal Poles



Delegates to the International Touring Parliament in Session at the Ministry of Foreign Affairs, Paris

NINE COUNTRIES AGREE TO UNIFORM TOURING REGULATIONS

PARIS, Oct. 20—The United States possessing varied automobile laws and regulations, was unable to take an active part in the international parliament held in Paris recently for the purpose of unifying regulations governing auto traffic throughout the world. This inability created considerable comment.

The net outcome of the meeting is that nine nations: France, Germany, Italy, Belgium, Bulgaria, Roumania, Montenegro, Servia, and the Principality of Monaco have signed an agreement which will materially simplify international automobile touring. In order that a car of any one of these nations may be allowed to enter free and without formality into any of the nine countries, all that is necessary is that it shall obtain an international road certificate from its home authorities.

What the Certificate Requires

The certificate, which is good for one year from date of issue, is issued for both car and driver on the fulfilment of certain requirements. The machine must be up to a certain standard, which is practically that of the Service des Mines in France, the points of which are safety from fire and explosion, effective steering, two independent sets of brakes, and simplicity of control. The driver must not be less than eighteen years of age, and must give proof of his ability to handle a car in a safe manner to the satisfaction of the examining authorities.

With driver and car up to standard, the automobilist may go forth into any or all of these nine countries without any other driving license or the necessity for any other registration number than that issued by his own country. The move is an important one, and will be specially appreciated by those visiting France, Germany, Belgium, and Italy, which are the most extensively toured countries in Europe.

England and America Not Included

It will be noted that England, in addition to America, has failed to join the international group. English regulations are very similar to those of America: any car can be put on the road providing taxation is paid, and any man can have a driving license on making application for it and paying the necessary fee. To come into line with the others it would have been necessary to institute an examination of cars, with a special registration other than that for taxation purposes, and further it would have been necessary to establish an examination for drivers with an accompanying registration, as is now done in France, Germany and other countries. The English delegates, evidently, could not guarantee that their government would do this, and were consequently unable to sign. There is a possibility of Great Britain coming into line at a later date. In fact, it approaches a certainty.

Pass to the Right and Keep to the Left
